# How to use the MICROPAEDIA

The 12 volumes of the MICROPAEDIA contain tens of thousands of shorter articles on specific persons, places, things, and ideas, arranged in alphabetical order. The MICROPAEDIA can be used as an information resource on its own; and it can function as support for the longer articles in the MACROPAEDIA (to which it refers whenever appropriate). The MICROPAEDIA in turn is supported by references in the INDEX and by the lists of suggested readings in the PROPAEDIA. Finally, the MICROPAEDIA is the portion of the *Encyclopædia Britannica* best suited for the reader who wishes to browse among the countless subjects in all fields of human learning and history in all times and places.

---

## Alphabetization

Entry titles are alphabetized according to the English alphabet, A to Z. All diacritical marks (such as in ö, ð, or ñ) and foreign letters without parallels in English (such as ayin [ʿ] and hamza [ʾ]) are ignored in the alphabetization. Apostrophes likewise are ignored. Titles beginning with numbers, such as **1812, War of**, are alphabetized as if the numbers were written out (**Eighteen-twelve, War of**).

Alphabetization proceeds according to the “word-by-word” principle. Thus, **Mount Vernon** precedes **mountain**; any **John** entry precedes **John Henry**, which in turn precedes **Johne’s disease**. Any character or string of characters preceding a space, hyphen, or dash is treated as a word and alphabetized accordingly. Thus, **De Broglie** precedes **debenture**, and **jack-o’-lantern** precedes **jackal**. Titles with identical spellings are arranged in the following order: (1) persons, (2) places, (3) things.

For many rulers and titled nobility, chronological order, as well as alphabetical order, governs placement. Rulers of the same given name (e.g., **William**) may be grouped together, separate from other entries, and indicated by the symbol ●. They may be subgrouped alphabetically by country and, within each country, arranged chronologically (**William I, William II**, etc.). Nobility or peers of the same titled name (e.g., **Essex, EARLS OF**) are similarly grouped together, separate from other entries; they are indicated by the symbol ● and arranged chronologically.

Places with identical names are arranged in the alphabetical order of the countries where they are located. Identical place-names in the same country are alphabetized according to the alphabetical order of the state, province, or other political subdivision where they are found.

---

## Entry arrangement

The titles of entries are arranged according to the forms commonly found in indexes and dictionaries, with some special conventions.

Entry titles for certain physical features, institutions, structures, events, and concepts are ordinarily inverted to place the substantive word first. Thus, the Bay of Bengal is entered as **Bengal, Bay of**; the Bank of England as **England, Bank of**; the Tower of London as **London, Tower of**; the Siege of Vienna as **Vienna, Siege of**; and the balance of power as **power, balance of**. If the name of a physical feature, institution, structure, event, or concept has two or more descriptors, it is entered under the descriptor appearing first. Thus, the Episcopal Church in Scotland is entered as **Episcopal Church in Scotland** (not **Scotland, Episcopal Church in**); the Leaning Tower of Pisa as **Leaning Tower of Pisa**; and the kinetic theory of gases as **kinetic theory of gases**.

The entries for most Western persons are arranged so that one can read a name in correct order by beginning after the first comma, proceeding to the end of the boldface type, returning to the beginning word or words, and proceeding forward to the first comma. Thus, the entry **March, Patrick Dunbar, 2nd Earl of**, is read “Patrick Dunbar, 2nd Earl of March”; the entry **Orléans, Louis, duc d’**, is read “Louis, duc d’Orléans.” Names of Far Eastern origin are given in Oriental order, with the surname preceding the personal name (e.g., **Tojō Hideki, Deng Xiaoping, Nguyen Cao Ky**).

---

## Cross-references

Some cross-reference entries appear in the MICROPAEDIA for the purpose of leading a reader from names that are familiar to alternate names that may not be. Cross-references also appear frequently within or at the ends of standard entries, where they are identified by *see*, *see also*, *see under*, *q.v.* (*quod vide*, “which see”), or *qq.v.* (*quae vide*, “which see,” plural).

Certain entries serve both as relatively brief essays on general subjects and as cross-references to the same subjects treated at greater length and in greater depth in the MACROPAEDIA. Such an entry (e.g., **igneous rock**) begins with a definition of the subject and then provides the following cross-reference: “A brief treatment of igneous rocks follows. For full treatment, *see* MACROPAEDIA: Minerals and Rocks.

Entries on certain broad subjects (e.g., **music**) direct the reader to several relevant articles in the MACROPAEDIA and also to the PROPAEDIA for listings of related articles in the MICROPAEDIA.

---

## Abbreviations

Abbreviations used in the MICROPAEDIA are given in a list that appears at the end of every MICROPAEDIA volume.

---

## Territorial boundaries

In articles and maps indicating disputed geopolitical boundaries and territories, the attribution of sovereignty or administrative subordination to any specific area does not imply recognition of the status claimed by an administering power.

**Freon** (trademark), any of several chlorofluorocarbons (CFCs) that are used in commerce and industry. The CFCs are a group of aliphatic organic compounds containing the elements carbon and fluorine and, in many cases, other halogens (especially chlorine) and hydrogen. The name Freon is a trademark registered by the E.I. du Pont de Nemours & Company.

The Freons are colourless, odourless, non-flammable, noncorrosive gases or liquids of low toxicity that were introduced as refrigerants in the 1930s; they also proved useful as propellants for aerosols and in numerous technical applications. Their low boiling points, low surface tension, and low viscosity make them especially useful refrigerants. The presence of fluorine atoms in Freon molecules makes them extremely stable, inert compounds that are entirely harmless to humans. The Freons neither present a fire hazard nor give off a detectable odour in their circulation through refrigerating and air-conditioning systems. The most important members of the group have been dichlorodifluoromethane (Freon 12), trichlorofluoromethane (Freon 11), chlorodifluoromethane (Freon 22), dichlorotetrafluoroethane (Freon 114), and trichlorotrifluoroethane (Freon 113).

In the mid-1970s it was suggested that Freons and other CFCs were, by chemical reaction, destroying the ozone present in the stratosphere. Depletion of the ozone could create a threat to animal life on the Earth because ozone absorbs ultraviolet radiation that can induce skin cancer. The use of Freons in aerosol-spray containers was banned in the United States in the late 1970s. By the early 1990s, accumulating evidence of ozone depletion in the polar regions had heightened worldwide public alarm over the problem, and in 1992 most of the developed nations agreed to end their production of Freons and other CFCs by 1996. *See also* chlorofluorocarbon.

**frequency**, in physics, number of waves that pass a fixed point in unit time; also the number of cycles or vibrations undergone during one unit of time by a body in periodic motion (*q.v.*). A body in periodic motion is said to have undergone one cycle or one vibration after passing through a series of events or positions and returning to its original state. *See also* angular velocity; simple harmonic motion.

If the period, or time interval, required to complete one cycle or vibration is  $\frac{1}{2}$  second, the frequency is 2 per second; if the period is  $\frac{1}{100}$  of an hour, the frequency is 100 per hour. In general, the frequency is the reciprocal of the period, or time interval—*i.e.*,  $\text{frequency} = 1/\text{period} = 1/(\text{time interval})$ . The frequency with which the Moon revolves about the Earth is slightly more than 12 cycles per year; the frequency of the A string of a violin is 440 vibrations or cycles per second.

The symbols most often used for frequency are *f* and the Greek letters nu ( $\nu$ ) and omega ( $\omega$ ). Nu is used more often when specifying electromagnetic waves, such as light, X rays, and gamma rays; omega is mostly used by electrical engineers in referring to alternating current. Usually frequency is expressed in the hertz unit, named in honour of the 19th-century German physicist Heinrich Rudolf Hertz, one hertz being equal to one cycle per second, abbreviated Hz; one kilohertz (kHz) is 1,000 Hz, and one megahertz (MHz) is 1,000,000 Hz.

In spectroscopy another unit of frequency, the wave number (*q.v.*), is sometimes used.

**frequency meter**, device for measuring the repetitions per unit of time (customarily, a second) of a complete electromagnetic waveform. Various types of frequency meters are used. Many are instruments of the deflection type, ordinarily used for measuring low frequencies but capable of being used for frequencies as

high as 900 Hz. These operate by balancing two opposing forces. Changes in the frequency to be measured cause a change in this balance that can be measured by the deflection of a pointer on a scale. Deflection-type meters are of two types, electrically resonant circuits and ratiometers.

An example of a simple electrically resonant circuit is a moving-coil meter. In one version, this device possesses two coils tuned to different frequencies and connected at right angles to one another in such a way that the whole element, with attached pointer, can move. Frequencies in the middle of the meter's range cause the currents in the two coils to be approximately equal and the pointer to indicate the midpoint of a scale. Changes in frequency cause an imbalance in the currents in the two coils, causing them and, in turn, the pointer to move.

Another type of frequency meter, not of the deflection type, is the resonant-reed type, ordinarily used in ranges from 10 to 1,000 Hz, although special designs can operate at lower or higher frequencies. These work by means of specially tuned steel reeds that vibrate under the effect of electric current; only those reeds that are in resonance vibrate visibly, however.

**frequency modulation (FM)**, variation of the frequency of a carrier wave in accordance with the characteristics of a signal. *See* modulation.

**Frere, Sir Bartle, 1st Baronet**, in full SIR HENRY BARTLE EDWARDS, 1st Baronet FRERE (b. March 29, 1815, Brecknockshire, Wales—d. May 29, 1884, Wimbledon, Surrey, Eng.), British colonial administrator in India

Sir Bartle Frere, detail of an oil painting by Sir George Reid, 1881; in the National Portrait Gallery, London  
By courtesy of the National Portrait Gallery, London

and finally in South Africa, where his administration as high commissioner became highly controversial.

After graduation from the East India Company's college at Haileybury in 1834, Frere began his long career in the Indian civil service. As chief commissioner of Sindh from 1850 to 1859, he did much to foster the economic development of the region. During the Indian Mutiny of 1857 the Sindh remained relatively quiet, enabling Frere to send troop reinforcements to the neighbouring Punjab. He was rewarded with a knighthood and a place on the viceroy's council at Calcutta (1859–62).

After serving as governor of Bombay for five years, he returned to England as a member of the India Council (1867–77), in which posts he concerned himself with the development of Indian agriculture and communications and with educational improvements. He was created a baronet in 1876.

Lord Carnarvon, the British colonial secretary, sent Frere to the Cape Colony as governor and high commissioner in 1877 to carry out the planned confederation of British South Africa and the Boer republics. When he landed at Cape Town, Frere found the colony in turmoil. The colonists were unsympathetic to Carnarvon's plans, and the Transvaal Boers, whose lands had just been annexed by the

British, were leaning toward independence rather than federation. Carnarvon's resignation in January 1878 further weakened Frere's position, and Frere did little to calm matters. After being convinced that the Zulu were an obstacle to federation, he provoked a war with them in December 1878. The Zulu War ended in a British victory, but the shocking defeat of British forces at Isandhlwana (Jan. 22–23, 1879) and the war's high cost led to Frere's official censure. He was recalled after federation talks collapsed in August 1880.

**Frere, John** (b. Aug. 10, 1740, Roydon Hall, near Diss, Norfolk, Eng.—d. July 12, 1807, East Dereham, Norfolk), British antiquary and a founder of prehistoric archaeology.

Frere was a country squire and, from 1771, an active member of the Royal Society of Antiquaries. In 1790 he discovered Stone Age flint implements among some fossilized bones of extinct animals at Hoxne, near Diss. Anticipating later archaeological methods, Frere carefully noted and described the strata uncovered. Though fettered by the then-popular belief that the Earth had been created in 4004 BC, in reporting his findings (1797) Frere nevertheless suggested that the remains may have dated from a time considerably earlier than 4004. His report was politely received but had to wait some 60 years to be appreciated.

**Frere, John Hookham**, pseudonym WILLIAM AND ROBERT WHISTLECRAFT (b. May 21, 1769, London, Eng.—d. Jan. 7, 1846, Valletta, Malta), British diplomat and man of letters.

Frere was educated at Eton, where he met the future statesman George Canning (with whom he collaborated on *The Anti-Jacobin*), and at the University of Cambridge. He entered the Foreign Office, in 1799 becoming undersecretary of state for foreign affairs and in 1800 going to Portugal as envoy extraordinary. His diplomatic career ended disastrously in 1808, when he was blamed for endangering the British army by advising its commander, Sir John Moore, against retreat from the French to La Coruña, Spain. He was recalled and spent the rest of his life in retirement, residing in Malta after 1820.

Frere is remembered for witty parodies in *The Anti-Jacobin* (1797–98), a weekly that opposed revolution in England and abroad; for his brilliance as a translator; and for his experiments with metre. He reintroduced into English verse the Italian ottava rima, an eight-line stanza with a skillfully interwoven rhyme scheme, which he used effectively in his mock-heroic Arthurian epic *The Monks and the Giants* (1817–18). He also showed a mastery of metre in his translations of four plays by Aristophanes, the greatest of the Greek comic dramatists.

**Frère-Orban, Hubert Joseph Walther** (b. April 22, 1812, Liège, French Empire [now in Belgium]—d. Jan. 1, 1896, Brussels, Belg.), Belgian statesman and Liberal Party reformer who was twice prime minister (1868–70 and 1878–84).

A strong advocate of free trade, Frère-Orban played a prominent part in the Liberal movement while practicing law in Liège. He was sent in 1847 to the Chamber of Representatives as a member from that city. From 1847 to 1894 he served as the leading Liberal member of the lower house in addition to holding many ministerial posts. As minister of finance (1848–52), he founded the Banque Nationale, abolished the newspaper tax, reduced the postage, and modified the customs duties as a preliminary to a free-trade policy.

To facilitate negotiations for a new commercial treaty, he conceded to France a law of copyright, which proved highly unpopular in

Belgium. He resigned and the rest of the Cabinet soon followed him. While serving again as finance minister in 1857, he embodied his free-trade principles in commercial treaties with Great Britain and France and abolished

Frère-Orban, detail of an oil painting by Louis Gallait, 1880; in the Banque Nationale, Brussels

© A.C.L., Brussels

the *octroi* duties (local import taxes) and tolls on national roads. After becoming prime minister in 1868, he defeated a French attempt to gain control of the Luxembourg railways (1869). In his second term as prime minister, he provoked the bitter opposition of Belgium's Catholic party by establishing secular primary education (1879) and by breaking off diplomatic relations with the Vatican (1880). Although Frère-Orban grudgingly conceded an extension of the franchise (1883), the hostility of the Radicals and the discontent caused by a financial crisis resulted in the overthrow of his government in the elections of 1884. He continued to lead the Liberal opposition until 1894.

**Fréron, Louis**, in full LOUIS-MARIE-STANISLAS FRÉRON (b. Aug. 17, 1754, Paris, France—d. July 15, 1802, Santo Domingo, Hispaniola [now in Dominican Republic]), journalist of the French Revolution and leader of the *jeunesse dorée* ("gilded youth") who terrorized Jacobins (radical democrats) during the Thermidorian reaction that followed the collapse of the Jacobin regime of 1793–94.

His father, Élie-Catherine Fréron, was the editor of *L'Année Littéraire* ("The Literary Year"), which combated the ideas of Voltaire and other Philosophes. Louis took over the management of the journal upon his father's death in 1776, and, soon after the outbreak of the Revolution in 1789, he founded the newspaper *L'Orateur du Peuple* ("The Spokesman of the People"), which violently attacked the new system of constitutional monarchy.

After King Louis XVI's abortive flight from Paris in June 1791, Fréron called for the king's execution. Threatened with arrest, Fréron went into hiding until the monarchy was

Louis Fréron

By courtesy of the Bibliothèque Nationale, Paris

overthrown on Aug. 10, 1792. He sat with the Montagnards (deputies from the Jacobin Club) in the revolutionary National Convention, which convened in September 1792, and in March 1793 he was sent to suppress counterrevolutionary activity at Marseille and Toulon. In both cities, Fréron ordered mass executions of hundreds of captured insurgents. As a result, Robespierre, chief spokesman for the Jacobin regime, had Fréron recalled in March 1794. Fearing that Robespierre intended to order his execution, Fréron became one of the most active participants in the conspiracy that brought about Robespierre's downfall on 9 Thermidor (July 27, 1794). In the ensuing Thermidorian reaction, Fréron vigorously denounced the Jacobins in *L'Orateur du Peuple* and organized the gangs of fashionably dressed *jeunesse dorée* who assaulted Jacobin workmen in the streets. He led the raid on the Parisian Jacobin Club that gave the government an excuse to order the club closed in November 1794. In November 1801, two years after Napoleon Bonaparte came to power, Fréron was appointed subprefect of Santo Domingo.

**fresco painting**, method of painting water-based pigments on freshly applied plaster, usually on wall surfaces. The colours, which are made by grinding dry-powder pigments in pure water, dry and set with the plaster to become a permanent part of the wall. Fresco painting is ideal for making murals because it lends itself to a monumental style, is durable, and has a matte surface.

Buon', or "true," fresco is the most durable technique and consists of the following process. Three successive coats of specially prepared plaster, sand, and sometimes marble dust are troweled onto a wall. Each of the first two rough coats is applied and then allowed to set (dry and harden). In the meantime, the artist, who has made a full-scale cartoon (preparatory drawing) of the image that he intends to paint, transfers the outlines of the design onto the wall from a tracing made of the cartoon. The final, smooth coat (intonaco) of plaster is then troweled onto as much of the wall as can be painted in one session. The boundaries of this area are confined carefully along contour lines, so that the edges, or joints, of each successive section of fresh plastering are imperceptible. The tracing is then held against the fresh intonaco and lined up carefully with the adjacent sections of painted wall, and its pertinent contours and interior lines are traced onto the fresh plaster; this faint but accurate drawing serves as a guide for painting the image in colour.

A correctly prepared intonaco will hold its moisture for many hours. When the painter dilutes his colours with water and applies them with brushstrokes to the plaster, the colours are imbedded into the surface, and as the wall dries and sets, the pigment particles become bound or cemented along with the lime and sand particles. This gives the colours great permanence and resistance to aging, since they are an integral part of the wall surface, rather than a superimposed layer of paint on it. The medium of fresco makes great demands on a painter's technical skill, since he must work fast (while the plaster is wet) but cannot correct mistakes by overpainting; this must be done on a fresh coat of plaster or by using the *secco* method.

*Secco* ("dry") fresco is a somewhat superficial process that dispenses with the complex preparation of the wall with wet plaster. Instead, dry, finished walls are soaked with limewater and painted while wet. The colours do not penetrate into the plaster but form a surface film, like any other paint. *Secco* has always held an inferior position to true fresco, but it is useful for retouching the latter.

The origins of fresco painting are unknown, but it was used as early as the Minoan civ-

"Delphic Sibyl," fresco by Michelangelo, 1508–12; in the Sistine Chapel, Vatican

SCALA/Art Resource

ilization (at Knossos on Crete) and by the ancient Romans (at Pompeii). The Italian Renaissance was the great period of fresco painting, as seen in the works of Cimabue, Giotto, Masaccio, Fra Angelico, Correggio, and many other painters from the late 13th to the mid-16th century. Michelangelo's paintings in the Sistine Chapel and Raphael's Stanza murals in the Vatican are the most famous of all frescoes. By the mid-16th century, however, the use of fresco had largely been supplanted by oil painting. The technique was briefly revived by Diego Rivera and other Mexican Muralists in the first half of the 20th century.

**Frescobaldi FAMILY**, family of medieval bankers who were prominent in Florentine business and politics and who financed the wars of Edward I and II of England.

The Frescobaldi belonged to the wealthy "magnate" class and were important in the public affairs of Florence from the 12th century. In the 1290s the family split into Whites and Blacks, representing Florentine factions that became allied with the Ghibelline (imperial) and Guelf parties. By the early 14th century, only the White (Ghibelline) Frescobaldi remained. The family's conservatism virtually excluded it from government office from 1285 to 1433.

The Frescobaldi opened a branch in England in the 1270s, and in two decades their firm had risen to the position of royal bankers formerly occupied by the Riccardi company of Lucca, which had been driven into bankruptcy by loans for Edward I's wars in Wales and France. Between 1302 and 1310, the Frescobaldi loaned £150,000 to Edward I and II. In return they were given virtual control of the revenues of England, including the mint and the customs, and were granted lands, honours, and privileges. In 1310 Edward II's barons, jealous of the Italians' power, drew up ordinances forbidding the assignment of customs to foreigners and calling for the arrest of foreign merchants and seizure of their goods. Before the ordinances could be implemented, the Frescobaldi fled to the European continent, taking refuge at Avignon and then at Florence.

The Frescobaldi were active participants in the unsuccessful revolt of Florentine magnates in 1343, and consequently they were excluded from the democratic government when it was reinstated.

The family included several literary figures, among them the poet Dino Frescobaldi (died c. 1316) and Leonardo Frescobaldi, who visited Egypt and the Holy Land in 1384 and left a valuable historical account of the social and economic life of the countries he visited.

**Frescobaldi, Girolamo** (b. September 1583, Ferrara, Papal States—d. March 1, 1643, Rome), Italian organist and one of the

first great masters of organ composition. He strongly influenced the German Baroque school through the work of his pupils, J.J. Froberger and Franz Tunder. Frescobaldi began his public career as organist at the church of Sta. Maria in Trastevere in Rome, in 1607. He travelled to the Netherlands the same year and published his first work, a book of madrigals, in Antwerp. In 1608 he became organist at St. Peter's in Rome, and, except for the period when he was court organist at Florence (1628–34), he remained at St. Peter's until his death.

Frescobaldi's fame rests on his instrumental works. Among these, keyboard compositions predominate, but the canzone for unspecified instruments with basso continuo are of outstanding historical significance in the development of the trio sonata. They are of a transitional type that led to the fully developed trio sonata, which was the principal chamber music medium until it was displaced by the string quartet.

In 1608 Frescobaldi published 12 fantasias in open score that are notable for their variety and for contrapuntal mastery of the highest order. The textures are idiomatic in a way rarely found in earlier examples of the form. In 1624 he published, again in open score, a collection of 10 *ricercari*, 5 *canzoni*, and 11 *capriccios*. The composer's preface contains valuable information about performance: "Should the player find it tedious to play a piece right through he may choose such sections as he pleases, provided only that he ends in the main key. . . . The opening passages should be played slowly so that what follows may appear more animated. The player should broaden the tempo at cadences. . . ."

Much of Frescobaldi's keyboard music was intended for the harpsichord, as is made clear in the title of his *Toccate d'intavolature di cimbalo e organo* (1637). The volume includes also *partitas* on various melodies and pieces on ground basses. These show Frescobaldi's free inventiveness in genuine keyboard textures and figuration. The preface of another collection, first published in 1627, again gives information of great value to the interpretation of Baroque instrumental music: "Play the opening of a toccata slowly and *arpeggiando*. . . . If one hand has a trill, while the other plays a passage, do not play note against note, but play the trill rapidly and the other expressively." Such directions indicate the extent to which keyboard style had moved

to develop the modern principle of monothematic writing, which replaced the rapid presentation of a number of themes typical of the early *ricercar* and *canzone*.

**Fresenius, Carl Remigius** (b. Dec. 28, 1818, Frankfurt am Main—d. June 11, 1897, Wiesbaden, Prussia), German analytical chemist whose textbooks on qualitative analysis (1841) and quantitative analysis (1846) became standard works. They passed through many editions and were widely translated.

Apprenticed to an apothecary (1836), he became an assistant to Justus von Liebig at the

Fresenius, engraving after a photograph  
Bavaria-Verlag

University of Giessen (1841) and a privatdozent (1843). From 1845 he was active in scientific and technological education and research at Wiesbaden. Many of his papers appeared in the *Zeitschrift für Analytische Chemie* ("Journal of Analytical Chemistry"), which he founded (1862) and edited until his death.

**Freshfield, Douglas William** (b. April 27, 1845, London—d. Feb. 9, 1934, Forest Row, Sussex, Eng.), British mountaineer, explorer, geographer, and author who advocated the recognition of geography as an independent discipline in English universities (from 1884).

On an expedition to the central Caucasus Mountains (1868), Freshfield made the first ascent of Mt. Elbrus (18,510 feet), the highest peak in the range and in Russia west of the Ural Mountains. Later, he failed in attempts to climb the Himalayan mountain Kängchenjunga (1899; 28,208 feet) and the Ruwenzori Range in Central Africa (1905). Freshfield was secretary (1881–94) and president (1914–17) of the Royal Geographical Society and chairman of the Society of Authors (1908–09). Among his books are *Italian Alps* (1875), *The Exploration of the Caucasus* (1896), *Round Kängchenjunga* (1903), and two editions of *Murray's Guide to Switzerland*.

**Freshwater**, town, unitary district of Isle of Wight, historic county of Hampshire, England. It lies close to Alum Bay, notable for its many coloured sandstone cliffs and for the Needles, a group of chalk sea stacks.

Farringford House at Freshwater was the home of Alfred, Lord Tennyson, who is commemorated by a tablet in All Saints' Church and by a large cross on High Down. Pop. (1991) 7,317.

**freshwater duck:** see dabbling duck.

**freshwater jellyfish**, any medusa, or free-swimming form, of the genus *Craspedacusta*, class Hydrozoa (phylum Cnidaria). *Craspedacusta* is not a true jellyfish; true jellyfish are exclusively marine in habit.

*Craspedacusta sowerbyi*, which is widespread in freshwaters of the Northern Hemisphere, grows to about 2 centimetres (0.8 inch) in diameter. Several hundred short tentacles extend, fringelike, from the margins of the animal's bell-shaped body.

The medusoid form alternates in generations with a polypoid form (cylindrical, stalklike, and permanently attached to a surface). The polyp, about 2 millimetres (0.08 inch) high, produces a medusoid form by budding; *i.e.*, an extension of the main body breaks away. The medusa is either male or female, rather than bisexual, and produces eggs or sperm. These unite to form a planula, a free-swimming larva, that settles onto a surface and develops into a polyp. The *Craspedacusta* polyp is notable for its lack of tentacles.

**freshwater snail**, any of the approximately 5,000 snail species that live in lakes, ponds, and streams. Most are members of the subclass Pulmonata; some are members of the subclass Prosobranchia; both subclasses belong to the class Gastropoda. The southeastern United States has the greatest number of species; another notable location is Lake Tanganyika, in Africa.

Freshwater snails are distributed via birds' feet, wind-blown leaves, and floods. Several species are hosts of flatworms causing disease in warm-blooded animals; *e.g.*, schistosomiasis. Large forms used to keep aquariums clean include the amphibious snail *Ampullarius gigas*.

**freshwater sponge**, any of about 20 species of the genus *Spongilla* (class Demospongiae, siliceous sponges), a common, widely occur-

Freshwater sponge (*Spongilla*)

Larry West—The National Audubon Society Collection/Photo Researchers

ring group. *Spongilla* species are found in clean lake waters and slow streams.

Freshwater sponges are delicate in structure, growing as encrusting or branching masses. They usually appear greenish because of the algae that live on them. Freshwater sponges may attain a volume of more than 2,500 cubic centimetres (150 cubic inches). The larva of the spongillafly lives as a parasite on freshwater sponges.

**Fresnay, Pierre**, original name PIERRE-JULES-LOUIS LAUDENBACH (b. April 4, 1897, Paris—d. Jan. 9, 1975, Paris), versatile French actor who abandoned a career with the Comédie-Française for the challenge of the cinema. Groomed for the stage by his uncle, the actor Claude Garry, Fresnay made his first stage appearance in 1912 before entering the Paris Conservatory.

Admitted to the Comédie-Française as a pensionnaire (contract player) in 1915, he played 80 roles there, making a particular impression in the plays of Alfred de Musset, and became a *sociétaire* (life member) four years before he resigned in 1927. During the next 10 years he worked in England and the United States as well as in France. He was outstanding in the title roles in *Cyrano de Bergerac* (1928) and *Don Juan* (London, 1934). In London and New York City Fresnay made his English-language debut in Noël Coward's *Conversation Piece* (1934) opposite his wife, the actress Yvonne Printemps. Subsequently, the

Girolamo Frescobaldi, engraving by Christian Sas, c. 1619

By courtesy of the trustees of the British Museum, photograph, J.R. Freeman & Co. Ltd

away from its origin in transcriptions of vocal or instrumental compositions. Frescobaldi's remaining publication, the *Fiori musicali* of 1635, consists of organ music intended for liturgical use.

Frescobaldi's style is characterized by a dramatic inventiveness and a bold use of chromaticism, but these qualities were carefully subordinated to a logical, effective construction within the piece. He was one of the first

couple became managers of the Théâtre de la Michodière in Paris (1937).

Although he made several silent films, his reputation as a cinema actor was established with his portrayal of Marius in the screen adaptations of Marcel Pagnol's trilogy: *Marius* (1931), *Fanny* (1932), and *César* (1936). His appearance as the young French officer opposite Erich von Stroheim in Jean Renoir's *La Grande Illusion* (1937; *Grand Illusion*) was a high point in his film career, although his principal honours came for later works: the Venice Biennial Prize (1947) for *Monsieur Vincent* and awards for *Dieu à besoin des hommes* (1950; *God Needs Men*).

**Fresnel, Augustin-Jean** (b. May 10, 1788, Broglie, Fr.—d. July 14, 1827, Ville-d'Avray), French physicist who pioneered in optics and did much to establish the wave theory of light advanced by Thomas Young.

Fresnel, detail of an engraving by Ambroise Tardieu after a contemporary portrait, 1825

H. Roger-Vollet

Fresnel served as an engineer in various departments of France but lost his post temporarily during the period following Napoleon's return from Elba (1814). About that time he seems to have begun his researches in optics. He studied the aberration of light, created various devices for producing interference fringes, and, by applying mathematical analysis to his work, removed a number of objections to the wave theory.

With François Arago he studied the laws of the interference of polarized light. He obtained circularly polarized light and developed the use of compound lenses instead of mirrors for lighthouses. Although his work in optics received scant public recognition during his lifetime, Fresnel maintained that not even acclaim from distinguished colleagues could compare with the pleasure of discovering a theoretical truth or confirming a calculation experimentally.

**Fresnel lens**, succession of concentric rings, each consisting of an element of a simple lens, assembled in proper relationship on a flat surface to provide a short focal length (see illustration). The Fresnel lens is used particularly in lighthouses and searchlights to concentrate the light into a relatively narrow beam. It would be almost impossible to make a large lighthouse lens of the usual solid glass-disk

Cross section of a Fresnel lens indicating its construction

type because the thickness and weight would be prohibitive; the lighter Fresnel lens is constructed of elements that are separately ground and polished from suitable glass blanks and assembled to make up the complete lens.

A one-piece molded-glass Fresnel lens is convenient for spotlights, floodlights, railroad and traffic signals, and decorative lights in buildings. Cylindrical Fresnel lenses are used in shipboard lanterns to increase visibility.

A wide variety of thin Fresnel lenses are molded in plastic, the width of the rings being only a few thousandths of an inch, for use as field lenses with ground-glass screens in cameras and small projectors to increase the brightness of the outer parts of the screen.

Georges-Louis Leclerc de Buffon (1748) originated the idea of dividing a lens surface into concentric rings in order to reduce the weight significantly. In 1820 this idea was adopted by Augustin-Jean Fresnel in the construction of lighthouse lenses.

**Fresnillo**, in full FRESNILLO DE GONZÁLEZ ECHEVERRÍA, city, central Zacatecas state, north central Mexico. It lies on an interior plateau more than 7,000 ft (2,100 m) above sea level and northwest of Zacatecas city, the state capital. It was founded in 1554 and has been an important silver-mining centre since 1569. Limited quantities of gold, copper, lead, and zinc are also produced. Irrigation has increased grain and vegetable production in the area; the livestock industry dates from the colonial period. The city is accessible by highway and air and is near a major rail line. Pop. (2000 est.) 94,000.

**Fresno**, city, seat (1874) of Fresno county, central California, U.S., in the San Joaquin Valley. Settled in 1872 as a station on the Central (later Southern) Pacific Railroad, it became an agricultural community after the introduction of irrigation in the 1880s. It processes and markets cotton, grain, fruits, wines, sugar beets, and dairy products and is the site of the huge Sun Maid Raisin processing plant. Fresno (Spanish: "Ash Tree") is headquarters of the Sierra National Forest and is a gateway to resort areas of the Sierra Nevadas. It is the home of California State University, Fresno (1911), and Fresno City College (1910). Inc. 1885. Pop. (1990) city, 354,202; Fresno MSA, 667,490.

**fret**, also called KEY PATTERN, in decorative art and architecture, any one of several types of running or repeated ornament, consisting of lengths of straight lines or narrow bands,

Mosaic fret in S. Apollinare Nuovo, Ravenna, 6th century

Alinari—Art Resource/EB Inc

usually connected and at right angles to each other in T, L, or square-cornered G shapes, so arranged that the spaces between the lines or bands are approximately equal to the width of the bands. Occasionally the system is arranged so that the lines intersect or interlace, as in the common swastika fret. Because the fret is one of the simplest and most natural of decorative forms, it is one of the most widely spread, found from early times in most art forms and on all continents. Thus, it was a favourite decoration, during and after the 4th dynasty, for the ceilings of tombs in Egypt, where in later examples it was combined with rosettes, scarabs, and the lotus into patterns of great richness.

In America the design has been found in early Peruvian textiles, on extant sculpture and architecture of the Mayan and Aztec cultures in Meso-America, and as a universal pottery decoration among American Indians.

Highly developed by both the Chinese and the Japanese for textiles as well as for architectural ornament, the fret occurs not only as a band but also as a complicated all-over pattern, sometimes with acute and obtuse angles instead of the more usual right angles. Its most important development, however, came at the hands of the Greeks (hence the common name Greek fret or Greek key), who used it for pottery and for painted decoration of architectural members, such as the abaci of capitals, where it was later carved.

Like so many Greek motifs, the fret was widely used by the Romans, particularly in Syria (e.g., the propylaea at Damascus and the great temple at Baalbek), and it occurs in Byzantine and Romanesque work.

Fretwork, either painted or carved, is the most often used of any small-scale repeated ornament in which geometrical forms occur.

**Freud, Anna** (b. Dec. 3, 1895, Vienna—d. Oct. 9, 1982, London), Austrian-born British founder of child psychoanalysis and one of its foremost practitioners. She also made fundamental contributions to understanding how the ego, or consciousness, functions in averting painful ideas, impulses, and feelings.

Anna Freud, c. 1970

Archiv für Kunst und Geschichte, West Berlin

The youngest daughter of Sigmund Freud, Anna was devoted to her father and enjoyed an intimate association with developing psychoanalytic theory and practice. As a young woman she taught elementary school, and her daily observation of children drew her to child psychology. While serving as chairman of the Vienna Psycho-Analytic Society (1925–28), she published a paper (1927) outlining her approach to child psychoanalysis.

Publication of Anna Freud's *Das Ich und die Abwehrmechanismen* (1936; *The Ego and Mechanisms of Defense*, 1937) gave a strong, new impetus to ego psychology. The principal human defense mechanism, she indicated, is repression, an unconscious process that develops as the young child learns that some impulses, if acted upon, could prove dangerous to himself. Other mechanisms she described include the projection of one's own feeling into another; directing aggressive impulses against the self (suicide being the extreme example); identification with an overpowering aggressor; and the divorce of ideas from feelings. The work also was a pioneer effort in the development of adolescent psychology.

In 1938 Anna Freud and her father, whom she had cared for during a number of years of his terminal illness, escaped from Nazi-dominated Austria and settled in London, where she worked at a Hampstead nursery until 1945. During World War II she and a U.S. associate, Dorothy Burlingham, recounted their work in *Young Children in Wartime* (1942), *Infants Without Families* (1943), and *War and Children* (1943).

Anna Freud founded the Hampstead Child

Therapy Course and Clinic, London, in 1947 and served as its director from 1952 to 1982. She viewed play as the child's adaptation to reality but not necessarily as a revelation of unconscious conflicts. She worked closely with parents and believed that analysis should have an educational influence on the child. A summation of her thought is to be found in her *Normality and Pathology in Childhood* (1968).

**Freud, Sigmund** (b. May 6, 1856, Freiberg, Moravia, Austrian Empire [now Příbor, Czech Republic]—d. Sept. 23, 1939, London, Eng.), Austrian neurologist, founder of psychoanalysis. Freudian theory had a great effect on psychology, psychiatry, and other fields.

A brief treatment of Sigmund Freud follows. For full treatment, see *MACROPAEDIA: Freud*.

Freud entered the University of Vienna in 1873 as a medical student and the General Hospital of Vienna in 1882. In 1885 he went to Paris to study with the neurologist Jean-Martin Charcot, which proved a turning point in his career. Charcot's work with patients classified as hysterics introduced Freud to the possibility that mental disorders might be caused by purely psychological factors rather than by organic brain disease.

Upon his return to Vienna, Freud entered into a fruitful partnership with the physician Josef Breuer. They collaborated on *Studien über Hysterie* (1895; *Studies in Hysteria*), which contains a presentation of Freud's pioneering psychoanalytic method of free association. It was this method that allowed Freud to arrive at numerous new insights: he developed theories concerning the deeper layers of the mind, the unconscious; he arrived at an understanding of neuroses; and in 1899 he published *Die Traumdeutung* (*The Interpretation of Dreams*), in which he analyzed the highly complex symbolic processes underlying dream formation. In 1905 appeared his controversial study *Drei Abhandlungen zur Sexualtheorie* (*Three Essays on the Theory of Sexuality*), in which he presented his discoveries concerning infantile sexuality and in which he delineated the complicated stages of psychosexual development, including the formation of the Oedipus complex.

Freud also applied his psychoanalytic insights to mythological, anthropological, cultural, and religious phenomena. Among his most noted works in this vein are *Totem und Tabu* (1913; *Totem and Taboo*) and *Das Unbehagen in der Kultur* (1930; *Civilization and Its Discontents*).

**Freudenstadt**, city, Baden-Württemberg Land (state), southwestern Germany, in the Black Forest (Schwarzwald). Founded in 1599 as a refuge for Protestants from Salzburg, Freudenstadt ("Town of Joy") was severely damaged by fire during World War II. The central city, including the Renaissance arcades in the marketplace and the Evangelical church (1601–08), was rebuilt in its original form. The town is a winter sports centre and one of the most frequented resorts in the Black Forest. Its spa has been reconstructed with modern facilities. Pop. (2003 est.) 23,884.

**Freudenthal, Axel Olof** (b. Dec. 12, 1836, Sjundea, Fin.—d. June 2, 1911), philologist, Swedish nationalist, and the leading ideologist for the nationalist movement of Finland's Swedish minority in the 19th century.

An adherent of the Pan-Scandinavian movement while still a student in the 1850s, Freudenthal was strongly influenced by one of the leaders of the movement, August Sohlman, a Swedish journalist who had written a racist defense of Finland's dominant Swedish minority against the claims of the Finnish nationalist movement.

Basing his position largely on Sohlman's views, Freudenthal, after becoming professor of Swedish language and literature at the University of Helsinki (1878–1904), devel-

oped the notion that nationality is primarily determined by language and that, by forsaking Swedish for Finnish, the educated classes would therefore be destroying the Swedish nation in Finland. He further maintained that because Finland had advanced culturally under Swedish influence, the annihilation of the Swedish cultural element would mean general decline. The Svecoman (Swedish nationalist) movement that arose in the 1860s based itself on Freudenthal's ideology.

**Freudian criticism**, literary criticism that uses the psychoanalytic theory of Sigmund Freud to interpret a work in terms of the known psychological conflicts of its author or, conversely, to construct the author's psychic life from unconscious revelations in his work.

Freudian critics depart from the traditional scope of criticism in reconstructing an author's psychic life on the basis of his writings. Edmund Wilson's *Wound and the Bow* (1941) explored this realm, and Van Wyck Brooks used this approach to biography in works such as *The Ordeal of Mark Twain* (1920). Professional analysts have applied their techniques to literature, notably Ernest Jones in *Hamlet and Oedipus* (1910 and 1949), which traces the famous problem of Hamlet's irresolution back to William Shakespeare's own Oedipal guilt.

**Freundsberg, Georg von:** see *Fruntsberg, Georg von*.

**Frey, Adolf** (b. Feb. 18, 1855, Külligen, near Aarau, Switz.—d. Feb. 12, 1920, Zürich), Swiss novelist, poet, and literary historian, whose most lasting achievements are his biographies of Swiss writers and his Swiss-German dialect poetry.

Adolf Frey

By courtesy of the Bibliotheque Nationale Suisse, Bern

As a biographer Frey showed a predilection for rich character studies in the manner of the 19th-century realists. Because he knew many writers and painters when he was a professor of German literature at Zürich (1898–1920), his portraits of them contain important personal material. Among these biographies are *Erinnerungen an G. Keller* (1892), *C.F. Meyer* (1899), *A. Böcklin* (1903), and *Der Tiermaler R. Koller* (1906). With his poetry, notably *Duss und uderm Rafe* (1891), rooted in the style of the folk song, he helped inaugurate creative and stylistic developments in Swiss poetry. His historical novels, such as *Die Jungfer von Wattenwil* (1912; "The Maiden of Wattenwil"), and his plays are considered to be of less importance.

**Frey, Roger** (b. June 11, 1913, Nouméa, New Caledonia—d. Sept. 13, 1997, Neuilly-sur-Seine, France), French Gaullist politician, considered a brilliant administrator with a flair for reform.

Frey was reared in New Caledonia. When World War II broke out, he rallied to Charles de Gaulle in 1940 and served in the Italian, French, and German campaigns. He was a key member (1947–52) of the Rally of the French People (RPF), which was the fledgling Gaullist party. Frey was a critical component of the

movement in the Fourth Republic to restore de Gaulle to power. He managed, with consummate skill, to merge different and sometimes contentious pro-de Gaulle groups and fuse them into the Union for the New Republic (UNR). After serving as secretary-general of the UNR (1958–59) when de Gaulle came to power, Frey served in nearly every cabinet under de Gaulle and his successor, Georges Pompidou. He was minister of information (1959), minister of the interior (1961–67), and minister of state (1967–72). Elected deputy successively from 1962 on, Frey left his seat in the National Assembly in 1974 to serve as president of the Constitutional Council (until 1983).

**Frey-Wyssling, Albert F(riedrich)** (b. Nov. 8, 1900, Küsnacht, Switz.—d. Aug. 30, 1988), Swiss botanist and pioneer of submicroscopic morphology, who helped to initiate the study later known as molecular biology.

Frey-Wyssling was educated at the Federal Institute of Technology, Zürich, at the University of Jena, and at the Sorbonne. From 1928 to 1932 he was a plant physiologist at Medan, Sumatra. He became a lecturer at the Federal Institute of Technology (1932), served as a professor in the department of botany and plant physiology (1938–70), and was also rector of the institution (1957–61).

In 1938 he began his studies in submicroscopic morphology, using polarizing microscopy and other optical techniques to obtain indirect evidence concerning submicroscopic structures. He held that the studies of the histologists (those who deal with structures discernible through the microscope) and of the physiological chemists, who study submicroscopic structures, would eventually be unified on the level of macromolecular chemistry. This subject, later known as molecular biology, became a practical reality with the application of the electron microscope in biological research (1940). Frey-Wyssling found that the basic concepts he evolved from his indirect methods were corroborated by the direct imaging of submicroscopic structures with the electron microscope. He wrote several books based on his submicroscopic studies.

**Freyberg (of Wellington and of Munstead), Bernard Cyril Freyberg, 1st Baron**, also called (1942–51) SIR BERNARD CYRIL FREYBERG (b. March 21, 1889, Richmond, Surrey, Eng.—d. July 4, 1963, Windsor, Berkshire), commander in chief of the New Zealand forces in World War II and governor-general of New Zealand from 1946 to 1952.

In 1891 Freyberg immigrated with his parents to New Zealand and was educated at Wellington College. He soldiered in the territorial army in New Zealand in 1911–12, and early in World War I he took part in the retreat from Antwerp and in the operations in Gallipoli. Later, in France, he fought in many of the fiercest battles and was awarded the Victoria Cross in December 1917. He was promoted to brigadier general at 27, then the youngest of that rank in the British army. He commanded the 29th Division in 1917–18. Freyberg was nine times wounded, and his bravery became legendary.

Between the wars he held senior staff appointments and a command in England. In World War II, as major general, he commanded the New Zealand Expeditionary Force (1939–45) and commanded the Allied forces during the battle for control of Crete in 1941. Later in the war he fought in North Africa and in Italy under Montgomery and Alexander. In 1942 he received a knighthood. Freyberg in 1946 became governor-general of New Zealand, an appointment he held for six years. In 1951 he was created a baron.

**Freycinet, Charles-Louis de Saulces de** (b. Nov. 14, 1828, Foix, Fr.—d. May 15, 1923, Paris), French political figure who served in 12 different governments, including four terms as premier; he was primarily responsible for important military reforms instituted in the last decade of the 19th century.

Freycinet graduated from the École Polytechnique and entered government service as a mining engineer, eventually rising to the position of inspector general of mines in 1883. Upon the establishment of the French Republic in September 1870, during the Franco-German War, he offered his services to Léon Gambetta, who appointed him prefect of Tarn-et-Garonne and, in October, chief of the military Cabinet of the provisional government of national defense at Tours. It was largely Freycinet's powers of organization that

Charles de Freycinet, photograph by Nadar (Gaspard-Felix Tournachon) Archives Photographiques, Paris

enabled Gambetta to muster forces with which to oppose the advancing German armies. Freycinet's account of his experience, *La Guerre en Province pendant le siège de Paris, 1870-1871* ("The War in the Provinces During the Siege of Paris, 1870-71"), was published in 1871.

Freycinet was elected to the Senate in 1876. Joining Jules Dufaure's government as minister of public works the next year, he directed a policy—often called the Freycinet Plan—whereby the government purchased railroads and built extensive new railways and waterways. In December 1879 he became premier for the first of four terms, but the issue of state support for religious organizations soon brought about the fall of his Cabinet.

Freycinet headed a new government and simultaneously served as foreign minister in January–August 1882; this time it fell because of his decision to occupy the Isthmus of Suez. He was in and out of governments for the next 17 years; in 1887 he lost the presidential election to Sadi Carnot. In April 1888 he became the first civilian war minister since 1848. For the next five years, in five successive governments, including one of his own (1890–92), he directed an impressive reform of the Army, which included the introduction of three-year terms of service, the establishment of a general staff, and the creation of a supreme war council. In January 1893 he was forced to resign as war minister because of a financial scandal over the proposed construction of a Panama canal. He returned to the War Ministry briefly in 1899 and then served as minister without portfolio in 1915–16.

Freycinet became a member of the Académie Française in 1890. In addition to many technical and scientific works, he wrote his memoirs, *Souvenirs, 1848-1878* (1912).

**Freycinet, Louis-Claude de Saulces de** (b. Aug. 7, 1779, Montélimar, Fr.—d. Aug. 18, 1842, near Loriol, Fr.), French naval officer and cartographer who explored portions of Australia and islands in the Pacific Ocean.

In 1800 he joined Captain Nicolas Baudin on a voyage of exploration to southern and southwestern coastal Australia and Tasmania. After his return to Paris in 1804, he completed an account of this expedition, *Voyage de découvertes aux terres australes* (1807; "Voyage of Discovery to Southern Lands"), for which he also drew maps.

In 1817 he took command of *l'Uranie* to conduct magnetic and oceanographic researches in the Pacific. His wife, Rose, disguised as a sailor, was smuggled aboard and accompanied the voyage, which she described in a journal published in 1827. After a stop at Rio de Janeiro, *l'Uranie* rounded the Cape of Good Hope and visited Timor, north of Australia, and the Mariana and Hawaiian islands. Freycinet named Rose Island in the Samoa group for his wife.

On the return voyage from Sydney to France, via Cape Horn, *l'Uranie* was wrecked in the Falkland Islands, but the scientific data and specimens aboard were saved. Freycinet purchased an American whaler, renamed *la Physicienne*, and in it returned to France. Observations from the expedition were published in *Voyage autour du monde... sur les corvettes de S.M. "l'Uranie" et "la Physicienne,"* 13 vol. and four atlases (1824-44; "Voyage Around the World... in H.M. Corvettes *l'Uranie* and *la Physicienne*").

**Freycinet Peninsula**, peninsula extending south into the Tasman Sea from east-central Tasmania, Australia. Measuring about 14 miles (23 km) by 4 miles (6.5 km), with an area of 25 square miles (65 square km), it rises to a high point at Mount Freycinet (2,011 feet [613 m]), one of the peaks along a high central granite ridge known as the Hazards. The peninsula is joined to the mainland by twin sandspits. Off its southern tip lie the Schouten Passage and Island and, to the west, Oyster Bay. The promontory was surveyed in 1802 by the French captain Nicolas Baudin and was named after his lieutenant, Louis-Claude de Saulces de Freycinet. In 1916 part of the peninsula was made a national park, which is entered via the resort town of Coles Bay, 70 miles (115 km) northeast of Hobart.

**Freyja** (Old Norse: "Lady"), most renowned of the Norse goddesses, who was the sister and female counterpart of Freyr and was in charge of love, fertility, battle, and death. Her father was Njörd, the sea god. Pigs were sacred to her, and she rode a boar with golden bristles. A chariot drawn by cats was another of her vehicles. It was Freyja's privilege to choose one-half of the heroes slain in battle for her great hall in the Fölkvangar (the god Odin took the other half to Valhalla). She possessed a famous necklace called *Brisinga men*, which the trickster god Loki stole and Heimdall, the gods' watchman, recovered. Greedy and lascivious, Freyja was also credited with the evil act of teaching witchcraft to the Aesir (a tribe of gods). Like the Egyptian goddess Isis and the Greek Aphrodite, Freyja traveled through the world seeking a lost husband and weeping tears of gold. She was also known by four nicknames—Mardöll, Hörn, Gefn, and Syr.

**Freyr**, also spelled FREY, also called YNGVI, in Norse mythology, the ruler of peace and fertility, rain, and sunshine and the son of the sea god Njörd. Although originally one of the Vanir tribe, he was included with the Aesir. Gerd, daughter of the giant Gymir, was his wife. Worshipped especially in Sweden, he was also well-known in Norway and Iceland. His sister and female counterpart, Freyja, was goddess of love, fertility, battle, and death. The boar was sacred to both. Freyr and Freyja figure in many lays and stories of medieval Iceland.

**Freyre, Gilberto de Mello**, Freyre also spelled FREIRE (b. March 15, 1900, Recife, Braz.—d. July 18, 1987, Recife), sociologist,

considered the 20th-century pioneer in the sociology of the Brazilian northeast.

Freyre received a B.A. from Baylor University, Waco, Tex., and his M.A. from Columbia University in 1923. In 1926 he organized the first northeastern regional congress in Recife and published the "Regionalist Manifesto." He was joined in this endeavour by the northeast writers Jorge de Lima, José Américo de Almeida, José Lins do Rego, and Luís Jardim, among others.

Most of Freyre's numerous sociological essays are concerned with the socioeconomic development of the northeastern region of Brazil and the attempt to relate this pattern constructively to the Portuguese-speaking African nations. Freyre's basic premise is that, by reason of its wide Afro-European cultural experience prior to the discovery of Brazil, the Portuguese nationality was uniquely endowed to work out in the New World a successful multicultural and multiracial society that could be imitated to advantage elsewhere.

Among Freyre's numerous published works in Portuguese and English, the best-known is *Casa-grande e senzala* (1933; "The Big House and the Slave Quarters"; Eng. trans. *The Masters and the Slaves*), an account of the relationship between Brazil's Portuguese colonizers and their African slaves. His other works include *Sobrados e mucambos* (1936; "The Rich and the Servants"; Eng. trans. *The Mansions and the Shanties*), *Brazil: An Interpretation* (1945), *Nordeste* (1937; "The Northeast"), and *Ordem e progresso* (1959; "Order and Progress"). *Sobrados e mucambos* traces the processes of urbanization and the decline of the rural patriarchal society in Brazil.

Freyre organized several university departments of sociology in Brazil and was the prime mover in the first Congress of Afro-Brazilian Studies in 1934. In 1949 he represented Brazil in the UN General Assembly.

**Freyssinet, (Marie-) Eugène (-Léon)** (b. July 13, 1879, Objat, Fr.—d. June 8, 1962, St. Martin-Vésudie), French civil engineer who successfully developed pre-stressed concrete—i.e., concrete beams or girders in which steel wire is embedded under tension, greatly strengthening the concrete member.

Hangars at Orly Airport, near Paris, designed by Freyssinet, 1916-24

By courtesy of the Musée de l'Air, Paris

Appointed bridge and highway engineer at Moulins in 1905, Freyssinet designed and built many reinforced-concrete bridges, including one with a 300-foot (91-metre) span. From the end of World War I until 1928 he worked for a contracting firm, and in 1930 he completed the Plougastel Bridge across the Elorn River at Brest. With three 612-foot (187-metre) spans, this was the largest reinforced-concrete bridge constructed up to that time.

After 1928 Freyssinet devoted himself to the development of pre-stressed concrete and also to the manufacture of high-strength concrete. His most significant discovery was that only a high-strength steel at a high stress would achieve a permanent pre-stress in concrete. At first little recognized, Freyssinet's methods were successfully applied at the Gare Maritime (harbour station) at Le Havre, Fr., in 1933 and gradually became universally adopted. After

his invention in 1938 of a practical tool for applying tension to steel, the use of pre-stressed concrete became worldwide.

**Freytag, Gustav** (b. July 13, 1816, Kreuzburg, Silesia, Prussia—d. April 30, 1895, Wiesbaden, Ger.). German writer of realistic novels celebrating the merits of the middle classes.

After studying philology at Breslau and Berlin, Freytag became Privatdozent in German literature at the University of Breslau (1839), but he resigned after eight years to devote himself to writing. He was much excited by the revolutions of 1848 and became, with Julian Schmidt, joint editor of the Leipzig weekly *Die Grenzboten*, which he made into the leading organ of the middle-class liberals. He abhorred both the democratic radicalism of the *Jungdeutschen* ("Young Germany") and the escapism of the Romantics. From 1867 to 1870 he represented the national liberal party in the North German *Reichstag*, and he served at the headquarters of the 3rd Army in the Franco-German War until the battle of Sedan (1870).

His literary work was influenced by his early reading of English novelists, especially Sir Walter Scott and Charles Dickens, and of French plays. His name was made with the comedy *Die Journalisten* (1854; *The Journalists*), still regarded as one of the most successful German comedies, and he acquired an international reputation with his widely translated novel *Soll und Haben* (1855; *Debit and Credit*, 1857). It celebrates the solid bourgeois qualities of the German merchants, and the close relationships between people's characters and the work they do is well brought out. The success of the novel was such that its author was recognized as the leading German writer of his day. He attempted to realize a similar intention with *Die verlorene Handschrift* (1864; *The Lost Manuscript*, 1865), which depicts Leipzig university life in the same realistic manner, but the plot is much weaker and the effect less successful. His most ambitious literary work was the novel-cycle *Die Ahnen*, 6 vol. (1873–81) which unfolded the story of a German family from the 4th century AD up to Freytag's own time. His *Bilder aus der deutschen Vergangenheit*, 5 vol. (1859–67; partial Eng. trans. *Pictures of German Life*, 1862–63) were originally contributed to *Die Grenzboten* and give a vivid and popular account of the history of the Germans, in which Freytag stresses the idea of folk character as determinative in history. His collected works, *Gesammelte Werke*, 22 vol. (1886–88) were reissued, edited by E. Elster (12 vol.) in 1926.

**Fria**, town and administrative capital of Fria region, western Guinea, West Africa, near the Amaria Dam on the Konkouré River. The Fria Company's bauxite-reducing factory at nearby Kimbo was one of Africa's first alumina-processing plants and is Guinea's largest industrial enterprise. Bauxite deposits were discovered in 1954, and alumina was first exported in 1960 via rail to Conakry, 55 mi (88 km [91 mi by rail]) south. The site of the largest technical training school in the country, Fria also has a hospital, a stadium, a mosque, and a Roman Catholic mission (1959). The town is also the chief trade centre for a region inhabited mainly by the Susu (Soussou) people. Pop. (1983) region, 70,413.

**friar** (from Latin *frater* through French *frère*, "brother"), one belonging to a Roman Catholic religious order of mendicants. Formerly, friar was the title given to individual members of these orders, as Friar Laurence (in *Romeo and Juliet*), but this is no longer common. The 10 mendicant orders are the Dominicans, Franciscans, Augustinians (Augustian Hermits), Carmelites, Trinitarians, Mercedarians, Servites, Minims, Hospitallers of St. John of

God, and the Teutonic Order (the Austrian branch).

**Friar Lands Question**, problem confronting the U.S. government after the takeover of the Philippines from Spain in 1898, concerning the disposition of large landed estates owned by Spanish monastic orders on the islands.

For more than 300 years the Roman Catholic Church had been intimately involved with Spanish colonial government in the Philippines. During that time three religious orders—Dominicans, Augustinians, and Recollects—had acquired about one-tenth of all the improved land in the islands. The discontent of the Filipino peasants with this situation had been a contributing factor in the Philippine Revolution of 1896–98.

In the Treaty of Paris (1898), which settled the Spanish-American War, the U.S. government agreed to protect the friars' property rights, but it was clearly dangerous to allow them to return to their lands. An agreement was eventually reached under which the U.S. purchased 410,000 acres (about 170,000 hectares) for a sum of \$7,000,000. The land was then resold to tenant farmers on an installment basis. This solution was not entirely satisfactory; numerous disputes arose over the accuracy of surveys and terms of repayment. Continued monastic possession of certain parcels of land has been a source of contention ever since, as has the issue of land reform in general.

**Fribourg** (French), German FREIBURG, canton, western Switzerland, bounded by Lake Neuchâtel and the cantons of Vaud on the west and south and Bern on the east, with enclaves within Vaud. Occupying an area of 644 sq mi (1,669 sq km), it lies in an elevated plain (Swiss Plateau) and rises from flat land in the west through a hilly region up to the Pre-Alps in the south and east. The highest summits are to the south in La Gruyère district and include the Vanil Noir (7,836 ft [2,389 m]). The canton is bisected by the Saane River (La Sarine), which flows from south to north (to join the Aare), and by its tributaries. On the west, La Broye flows northeast into Lakes Morat (Murtensee) and Neuchâtel, and, in the southwest, La Veveyse flows south to Lake Geneva (Lac Léman).

Traces of prehistoric settlements have been found on the shores of Lakes Neuchâtel and Morat. The canton, made up of districts acquired by its capital, the city of Fribourg (*q.v.*), reached its present extent with the inclusion of Morat (now Murten) in 1803. It joined the Sonderbund (separatist league of Catholic cantons) in 1846 but surrendered to the federal army in 1847. Predominantly Roman Catholic, it has numerous monasteries and convents.

The canton is predominantly agricultural. Cattle breeding and dairying (including the processing of milk and cheese, notably in La Gruyère district) are important. Market gardening, cereals, tobacco, and fruit prosper in the fertile north and on hillsides in the centre of the canton. Light industries are largely concentrated in Fribourg city, Düdingen, and Murten and the timber industry in La Gruyère. Power plants in La Sarine district generate electricity for home use and for export. Tourism is most developed in the mountain and lake regions and in Fribourg. The canton is served by the main railway line from Lausanne to Bern, with several branch lines.

Situated on the Swiss linguistic frontier, Fribourg's population is two-thirds French speaking (west) and one-third German speaking (east). Pop. (1998 est.) 232,086.

**Fribourg** (French), German FREIBURG, capital of Fribourg canton, Switzerland, on a loop in La Sarine (Saane) River, southwest of Bern. Founded in 1157 by Berthold IV, duke of Zähringen, to control a ford across the river, it passed to the sons of Rudolf of

Habsburg in 1277. The Habsburgs abandoned it in 1452; it then accepted the suzerainty of the dukes of Savoy. Fribourg assisted the Swiss in defeating Charles the Bold of Burgundy at Grandson and Morat (now Murten) in 1476 and was admitted to full membership in the Swiss Confederation in 1481. Occupied by the French in 1798, Fribourg became part of the Helvetic Republic and then one of the cantons of the Swiss Confederation as reconstituted by Napoleon's Act of Mediation in 1803.

The oldest part of the city (the Bourg) is high above the river bank; the Neuveville, Auge, and Planche (Matte) quarters form the lower part (Basseville). West of the Bourg and still higher are the modern Places and Péroilles quarters. The old quarters retain much of their medieval appearance, characterized by Gothic-fronted houses and the remains of towers and gateways with 13th- to 17th-century ramparts, which originally surrounded the city. Medieval buildings include St. Nicholas Cathedral (13th–15th century) with a famous organ built by Aloys Mooser; the Franciscan church (Église des Cordeliers [1281; altered 1748]) with a 15th-century reredos; the former Augustinian Church of St. Maurice (1255) with a baroque reredos; and numerous chapels and

Fribourg, Switz., on the Sarine River, with the Point de Zähringen  
Josef Muench

former convents and monasteries. The town hall dates from 1506–22 with a tower of 1642. Modern architecture includes the university buildings (1941) and the Church of Christ the King (1954). The Sarine River is spanned by several bridges, notably the seven-arched Pont de Zähringen. The seat of the bishopric of Lausanne–Geneva–Fribourg and of a Roman Catholic state university (founded 1889), Fribourg is the centre of Swiss Catholicism. It possesses numerous works of art, mainly preserved in its churches and in the Musée d'Art et d'Histoire.

Situated on the main railway from Lausanne to Bern and a junction of lines to Murten and Payerne, the city is also a centre for bus and postal road services. There are breweries, a foundry, and factories for chocolate, cardboard boxes, machinery, electrical equipment, wood products, clothing, and chemicals. The population is primarily French speaking. Pop. (1998 est.) 31,939.

**fricative**, in phonetics, a consonant sound, such as English *f* or *v*, produced by bringing the mouth into position to block the passage of the airstream, but not making complete closure, so that air moving through the mouth generates audible friction.

Fricatives (also sometimes called "spirants") can be produced with the same positions of the vocal organs as stops; bilabial, labiodental, dental, alveolar, palatal, velar, and uvular consonants. In addition to the *f* and *v* sounds,

examples of fricatives in English are *s* as in "sitter," *z* as in "zebra," and the two *th* sounds as in "think" and "this."

**Frick, Henry Clay** (b. Dec. 19, 1849, West Overton, Pa., U.S.—d. Dec. 2, 1919, New York City), U.S. industrialist, art collector, and philanthropist who helped build the world's largest coke and steel operations.

Frick began building and operating coke ovens in 1870, and the following year he organized Frick and Company. Taking advantage of the difficult times following the financial panic of 1873, he acquired extensive coal deposits and supplied Pittsburgh with the coke required for its steel and iron industry.

In 1889 Frick was made chairman of Carnegie Brothers and Company to reorganize their steel business. He initiated far-reaching improvements and bought out Carnegie's chief competitor, the Duquesne Steel Works. He was responsible for building Carnegie into the largest manufacturer of steel and coke in the world. As a result of his leading role in the dispute during the Homestead (Pa.) steel strike of 1892, he was shot and stabbed by Alexander Berkman, an anarchist, but survived.

Frick played a major role in the formation of the United States Steel Corporation in 1901 and later became a director. He also served as a director of a number of railroads.

Upon his death Frick bequeathed \$15,000,000 and his Fifth Avenue mansion to New York City to establish the Frick Collection, a trove of paintings, bronzes, and enamels he had collected over a 40-year period. It is generally considered one of the great privately owned museums of the world. His other gifts include a 150-acre (61-hectare) park and a \$2,000,000 endowment to the city of Pittsburgh, as well as liberal contributions to Princeton University.

**Frick, Wilhelm** (b. March 12, 1877, Alsenz, Ger.—d. Oct. 16, 1946, Nürnberg), longtime parliamentary leader of the German National Socialist Party and Adolf Hitler's minister of the interior, who played a major role in drafting and carrying out the Nazis' anti-Semitic measures.

An official in the police administration at Munich, Frick was convicted of high treason for participating in Hitler's Munich (Beer Hall) Putsch of November 1923 but managed to avoid imprisonment. Elected to the Reichstag (parliament) in May 1924, he began to lead the Nazis in that body in 1928.

During 1930–31, as minister of the interior in the state government of Thuringia, Frick was the first Nazi to hold any ministerial-level post in Germany. Thereafter he became the recognized party expert in German domestic politics. As Hitler's national minister of the interior (1933–43), he played a significant role in devising and obtaining passage of legislation providing for government by decree (March 1933) and in drafting subsequent measures against the Jews, especially the notorious Nürnberg laws of September 1935.

With the growth of the SS (Schutzstaffel) as the state's principal internal-security force, however, Frick's importance in the government declined, and in 1943 he was replaced at the interior ministry by SS chief Heinrich Himmler. Thereafter Frick served as Reich protector for Bohemia and Moravia until the end of World War II. Arraigned before the Allied war-crimes tribunal at Nürnberg (1946), he was convicted and subsequently executed for his "crimes against humanity."

**Frick Collection**, gallery of paintings, sculpture, and decorative arts in New York City. The art, spanning the history of Western art from the Middle Ages to the late 19th century, was amassed by the industrialist Henry Clay

Frick (1849–1919) under the guidance of the art dealer Joseph Duveen and the English art critic Roger Fry.

The collection, as well as an art reference library, is housed in Frick's Manhattan townhouse. It includes decorative arts, drawings, furniture, paintings, prints, and sculpture.

**friction**, force that resists the sliding or rolling of one solid object over another. Frictional forces, such as the traction needed to walk without slipping, may be beneficial; but they also present a great measure of opposition to motion. About 20 percent of the engine power of automobiles is consumed in overcoming frictional forces in the moving parts.

The major cause of friction between metals appears to be the forces of attraction, known as adhesion, between the contact regions of the surfaces, which are always microscopically irregular. Friction arises from shearing these "welded" junctions and from the action of the irregularities of the harder surface plowing across the softer surface.

Two simple experimental facts characterize the friction of sliding solids. First, the amount of friction is nearly independent of the area of contact. If a brick is pulled along a table, the frictional force is the same whether the brick is lying flat or standing on end. Second, friction is proportional to the load or weight that presses the surfaces together. If a pile of three bricks is pulled along a table, the friction is three times greater than if one brick is pulled. Thus, the ratio of friction  $F$  to load  $L$  is constant. This constant ratio is called the coefficient of friction and is usually symbolized by the Greek letter mu ( $\mu$ ). Mathematically,  $\mu = F/L$ . Because both friction and load are measured in units of force (such as pounds or newtons), the coefficient of friction is dimensionless. The value of the coefficient of friction for a case of one or more bricks sliding on a clean wooden table is about 0.5, which implies that a force equal to half the weight of the bricks is required just to overcome friction in keeping the bricks moving along at a constant speed. The frictional force itself is directed oppositely to the motion of the object. Because the friction thus far described arises between surfaces in relative motion, it is called kinetic friction.

Static friction, in contrast, acts between surfaces at rest with respect to each other. The value of static friction varies between zero and the smallest force needed to start motion. This smallest force required to start motion, or to overcome static friction, is always greater than the force required to continue the motion, or to overcome kinetic friction.

Rolling friction occurs when a wheel, ball, or cylinder rolls freely over a surface, as in ball and roller bearings. The main source of friction in rolling appears to be dissipation of energy involved in deformation of the objects. If a hard ball is rolling on a level surface, the ball is somewhat flattened and the level surface somewhat indented in the regions in contact. The elastic deformation or compression produced at the leading section of the area in contact is a hindrance to motion that is not fully compensated as the substances spring back to normal shape at the trailing section. The internal losses in the two substances are similar to those that keep a ball from bouncing back to the level from which it is dropped. Coefficients of sliding friction are generally 100 to 1,000 times greater than coefficients of rolling friction for corresponding materials. This advantage was realized historically with the transition from sledge to wheel.

**friction drum**, musical instrument made of a membrane stretched across the mouth of a vessel and set in vibration by rubbing with wet or resined fingers a stick or string passed through the membrane or tied upright from underneath; in some types the membrane is rubbed with another piece of skin. Closer in

Flemish *rommelpot* friction drum; in the Musée Instrumental du Conservatoire Royal, Brussels

By courtesy of the Musée Instrumental, Brussels, photograph © A.C.L. Brussels

sound production to primitive friction, or rubbing, boards, it probably evolved separately from the beaten drum, which is associated with different rites in nonliterate societies.

The friction drum—found in Africa, Europe, Asia, and the Americas—is primarily a ritual instrument. In Europe this ritual association survives in places where the instrument has not become a toy—e.g., in Italian religious processions and Romanian New Year's festivities. Other European friction drums include the Flemish *rommelpot* and the Spanish *zambomba*.

**Friday**, sixth day of the week (*q.v.*).

**Fridolin of Säckingen, Saint** (b. Ireland—d. 6th or 7th century AD, Säckingen, Ger.; feast day March 6), Irish-born missionary who is said to have established churches among the Franks and Alamanni and who, in modern times, has been revered in southern Germany, Switzerland, and Austria.

Accounts of his life (generally unreliable and deriving principally from the 10th-century monk Balther of Säckingen) describe him as a man of noble birth who became an itinerant preacher in Ireland, travelling from town to town, and then crossed over to France. He lived for a while at a monastery at Poitiers and then travelled to the Rhine, building churches along the way. At Säckingen he purportedly founded a church and monastery, with a nunnery nearby.

**Fried, Alfred Hermann** (b. Nov. 11, 1864, Vienna—d. May 5, 1921, Vienna), Austrian pacifist, publicist, co-founder of the German peace movement, and co-winner (with Tobias Asser) of the Nobel Prize for Peace in 1911.

In 1891 Fried, in Berlin, founded the paci-

Fried

By courtesy of the Bild Archiv, Österreichische Nationalbibliothek, Vienna

first periodical *Die Waffen nieder!* ("Lay Down Your Arms!"), from 1899 called *Friedenswarte* ("The Peacekeeper"). In 1892 he founded the Deutsche Friedensgesellschaft (German Peace Society), which became the focus for the German pacifist movement before World War I. Fried advocated "fundamental pacifism" and believed that "international anarchy" should be met by both legislative measures and spiritual regeneration.

With the outbreak of World War I he immigrated to Switzerland in protest against German policy. As editor of *Blätter für internationale Verständigung und zwischenstaatliche Organisation* ("Papers for International Understanding and Inter-State Organization"), he worked for an immediate peace. Fried protested against the Treaty of Versailles but warned the Germans against attempting to revise it by force. His works include *Handbuch der Friedensbewegung*, 2 vol. (1911-13; "Handbook of the Peace Movement"), and *Mein Kriegstagebuch*, 4 vol. (1918-20; "My War Diary").

**Friedan, Betty (Naomi)**, *née* GOLDSTEIN (b. Feb. 4, 1921, Peoria, Ill., U.S.—d. Feb. 4, 2006, Washington, D.C.), American feminist best known for her book *The Feminine Mystique* (1963), which explored the causes of the frustrations of modern women in traditional roles.

Friedan earned a B.A. in psychology (1942) from Smith College, Northampton, Mass., and did graduate work at the University of California at Berkeley. She worked for a time in New York City but married in 1947 (divorced 1969), moved to the suburbs, and reared three children. Friedan's unhappiness with her role as housewife and mother coupled with the discovery that her dissatisfaction was shared by other women, prompted her to write *The Feminine Mystique*. One result of this work was her further involvement in the women's movement.

In 1966 Friedan cofounded and became the first president of the National Organization for Women (NOW). Her second book, *It Changed My Life* (1976), is an account of her campaigns of the 1960s and early '70s as recorded in speeches, essays, and interviews. In *The Second Stage* (1981) she assessed the status of the women's movement. Her other books include the memoir *Life So Far* (2000).

**Friedel, Charles** (b. March 12, 1832, Strasbourg, France—d. April 20, 1899, Montauban), French organic chemist and mineralogist who, with the American chemist James Mason Crafts, discovered in 1877 the chemical process known as the Friedel-Crafts reaction.

In 1854 Friedel entered C.A. Wurtz's laboratory and in 1856 was appointed conservator of the mineralogical collections at the Superior National School of Mines. In 1871 he began to lecture at the École Normale and in 1876 became professor of mineralogy at the Sorbonne, but on the death of Wurtz in 1884 he exchanged that position for the chair of organic chemistry.

He collaborated in efforts to form diamonds artificially, studied the pyroelectric properties of crystals, determined crystallographic constants, and did research on ketone and aldehyde compounds. Friedel was the chief founder of *Revue Générale de Chimie* in 1899.

**Friedel, Georges** (b. July 19, 1865, Mulhouse, France—d. Dec. 11, 1933, Strasbourg), French crystallographer, who formulated basic laws concerning the external morphology and internal structure of crystals.

Friedel studied at the École Polytechnique and the Superior National School of Mines, where his father, the chemist Charles Friedel, was curator of the mineralogical collections. After graduation he worked as a mining engineer and then turned to teaching and research,

first at the School of Mines of Saint-Étienne and later at the University of Strasbourg.

Friedel's observations established the general validity of the hypothesis, put forward by Auguste Bravais, that the different faces of crystals were external expressions of a periodic, internal arrangement of atoms, or lattice structure. His own law of rational symmetric intercepts (1905) and law of mean indices (1908) are generalizations of the regularities observed in the external symmetry of crystals. After conclusive proof of the lattice structure was achieved in 1912 by the X-ray diffraction experiments of Max von Laue, Friedel showed that, because the X-ray diffraction pattern is always symmetric, it is impossible (except under special circumstances) to determine whether the crystal actually has a centre of symmetry and that only 11 different types of crystal symmetry can be distinguished. This result is known as Friedel's law, and the 11 possible types of symmetry are known as Friedel classes (or Laue symmetry groups).

**Friedland, Battle of** (June 14, 1807), victory for Napoleon that compensated for a setback the preceding February at Eylau and led to the Treaty of Tilsit between Napoleon and Alexander I of Russia. It was fought at Friedland (modern Pravdinsk, Russia), 27 miles (43 km) southeast of Königsberg in East Prussia.

About 80,000 troops of Napoleon's Grand Army (including Polish, Dutch, Italian, and German units) confronted about 58,000 Russians under the command of General Leonty Leontyevich Bennigsen. Most of the Russian troops crossed to the west bank of the Alle River at Friedland and early on June 14 attacked the seemingly isolated French corps of Marshal Jean Lannes. Outnumbered by more than two to one, Lannes held off the Russian attacks, led by Prince P.I. Bagration, for nine hours while Napoleon concentrated his forces. At 5 PM Napoleon launched his main attack, employing about 65,000 men, and in two hours pushed the southern half of the Russian army back into the tiny village of Friedland. There, close-packed, they were cut down by volleys of canister and grapeshot fired by the French guns at close range. The Russians were either killed, captured, or driven into the river, since the bridges had earlier been destroyed by the French. The Russians lost about 19,000 men, and the French about 9,000. Bennigsen's army was shattered, and the next day his ally, the Prussian general Anton Lestocq, with about 25,000 men, abandoned Königsberg and retreated to Tilsit. The French occupied Königsberg.

**Friedman, Jerome Isaac** (b. March 28, 1930, Chicago, Ill., U.S.), American physicist who, together with Richard E. Taylor and Henry W. Kendall, received the Nobel Prize for Physics in 1990 for their joint experimental confirmation of the fundamental particles known as quarks.

Friedman was educated at the University of Chicago (Ph.D., 1956). After conducting research there and at Stanford University, where he met Taylor and Kendall, he began teaching at the Massachusetts Institute of Technology in 1960. He became a full professor there in 1967 and head of the physics department in 1983.

Friedman conducted his prizewinning research jointly with Kendall and Taylor at the Stanford Linear Accelerator Center of Stanford University. In a series of experiments from 1967 to 1973, the three physicists used a particle accelerator to direct a beam of high-energy electrons at target protons and neutrons. They found that the manner in which the electrons scattered from the targets indicated that both protons and neutrons are composed of hard, electrically charged, pointlike particles. As their experiments progressed, it became clear that these particles corresponded to the fundamental particles called quarks, whose existence

had been hypothesized in 1964 by Murray Gell-Mann and George Zweig.

**Friedman, Milton** (b. July 31, 1912, Brooklyn, N.Y., U.S.), American economist and educator, one of the leading proponents of monetarism in the second half of the 20th century. He was awarded the Nobel Prize for Economics in 1976.

Friedman was one year old when his family moved from Brooklyn, N.Y., to Rahway, N.J., where he grew up. He studied mathematics and economics at Rutgers University (B.A., 1932) and continued his economics studies at the University of Chicago (A.M., 1933) and Columbia University (Ph.D., 1946). In 1935 he assisted with a consumer budget study for the Natural Resources Committee in Washington, D.C. Two years later Friedman joined economist Simon Kuznets in a study of income and wealth distribution sponsored by the National Bureau of Economic Research. Friedman's finding—that barriers to entry sustained by the American Medical Association helped secure higher incomes for physicians—stirred controversy when it was published.

In 1946 he accepted a position in the economics department at the University of Chicago, which was his academic home for the next 30 years. As a specialist in price theory and monetary economics, Friedman established the Money and Banking Workshop, a critical forum for topics in monetary economics. Beyond the university he advised Presidents Richard M. Nixon and Ronald W. Reagan on economic policy and wrote an economics column for *Newsweek* magazine (1966-84). In areas of public policy, Friedman supported flexible exchange rates and a monetary growth rule, school vouchers, and balanced budgets; he opposed conscription and various forms of price controls—from the minimum wage to rent controls.

Friedman's contributions to economic theory are numerous. One of his earliest, described in *A Theory of the Consumption Function* (1957), was the articulation of the permanent income hypothesis—the idea that a household's consumption and savings decisions are more affected by changes in its permanent income than by income changes that household members perceive as temporary or transitory. This was Friedman's novel finding: households will maintain their established spending patterns if they believe income changes are temporary.

Friedman's best-known contributions are in the realm of monetary economics, where he is seen as the founder of monetarism. He became an articulate spokesman for free markets and free societies in an era when many social scientists disparaged market solutions to social problems. Friedman's collaborative work with Anna J. Schwartz, starting with *A Monetary History of the United States, 1867-1960* (1963), became an essential resource in the monetary history of the United States. Especially influential was the authors' claim that the Great Depression would have been a typical downturn had it not been for policy errors made by the Federal Reserve.

In 1977 Friedman became a member of the Hoover Institution in Palo Alto, Calif. He and his wife, Rose, published their memoirs, *Two Lucky People*, in 1998. (Br.J.C.)

**Friedman, William F(rederick); and Friedman, Elizabeth S(mith)**, *née* ELIZABETH SMITH (respectively b. Sept. 24, 1891, Chisinau, Russia [now in Moldova]—d. Nov. 2, 1969, Washington, D.C., U.S.; b. 1892, Huntington, Ind., U.S.—d. Oct. 31, 1980, Plainfield, N.J.), American cryptologists, who helped decipher enemy codes from World War I to World War II.

William Friedman was still an infant when

his family immigrated to the United States; he studied genetics at Cornell University (B.S., 1914). Elizabeth Smith majored in English at Hillsdale (Michigan) College (B.A., 1915). They met at the Riverbank Laboratories (Geneva, Ill.), where they both eventually became involved in cryptology, working often for the government in decoding diplomatic messages. In 1917–18 William served in the U.S. Army, partly in France, analyzing German code books.

After the war, in 1921, the Friedmans (they had married in May 1917) moved to Washington, D.C., where, over the years, Elizabeth Friedman worked for several government departments, notably cracking the codes used by rumrunners and other smugglers, and where William Friedman, in the War Department, became the chief cryptanalyst in the Signal Intelligence Service, notably leading the teams that broke various Japanese codes, including ultimately the Purple machine cipher initiated by Japan in 1939. After World War II, William Friedman worked awhile for the National Security Agency, and Elizabeth Friedman for the International Monetary Fund.

William Friedman wrote *The Index of Coincidence and Its Applications in Cryptography* (1922), one of the standard works in the nomenclature and classification of ciphers. Together, the Friedmans wrote *The Shakespearean Ciphers Examined* (1957), in which they denied Francis Bacon's purported authorship of the William Shakespeare plays and sonnets.

**Friedmann, Aleksandr Aleksandrovich**, Friedmann also spelled FRIDMAN (b. June 17 [June 29, New Style], 1888, St. Petersburg, Russia—d. Sept. 16, 1925, Leningrad [St. Petersburg]), Russian mathematician and physical scientist.

After graduating from the University of St. Petersburg in 1910, Friedmann joined the Pavlovsk Aerological Observatory and, during World War I, did aerological work for the Russian army. After the war he was on the staff of the University of Perm (1918–20) and then on the staffs of the Main Physical Observatory and other institutions until his death in 1925.

Friedmann was first to formulate (1922) the mathematics of a model universe in which the average mass density is constant and all fundamental parameters are known except the expansion factor, or radius of curvature. His model has been of great significance in the mathematical derivation of cosmological models from Albert Einstein's general theory of relativity. Friedmann was also one of the first to postulate (1922, 1924) a "big bang" model for the evolution of the universe. He was also a founder of the science of dynamic meteorology.

**Friedmann, Andrei:** see Capa, Robert.

**Friedrich** (German personal name): see under Frederick, except as below.

**Friedrich, Caspar David** (b. Sept. 5, 1774, Greifswald, Pomerania [Germany]—d. May 7, 1840, Dresden, Prussia [Germany]), pioneer early 19th-century German Romantic painter. His vast, mysterious landscapes and seascapes proclaimed man's helplessness against the forces of nature and did much to establish the idea of the sublime as central concerns of the Romantic movement.

Friedrich studied from 1794 to 1798 at the academy at Copenhagen but was largely self-taught. Settling at Dresden, he became a member of an artistic and literary circle that included the painter Philipp Otto Runge and the writers Ludwig Tieck and Novalis. His drawings in sepia, executed in his neat early style, won the poet J.W. von Goethe's

Self-portrait, drawing by Caspar David Friedrich; in the Kupferstichkabinett und Sammlung der Zeichnungen, Berlin

By courtesy of the Staatliche Museen zu Berlin

approval and a prize from the Weimar Art Society in 1805. His first important oil painting, "The Cross in the Mountains" (c. 1807), established his mature style, characterized by an overwhelming sense of isolation, and was an attempt to replace the traditional symbolism of religious painting with one drawn from nature. Other symbolic landscapes, such as "Shipwreck in the Ice" (1822), reveal his fatalism and obsession with death. Though based on close observation of nature, his works were coloured by his imaginative response to the atmosphere of the Baltic coast and the Harz Mountains, which he found both awesome and ominous. In 1824 he was made professor of the Dresden academy. For a long time his work was forgotten; but it was revived when the 20th century recognized its own existential isolation in his work.

**Friedrich August** (German personal name): see under Frederick Augustus.

**Friedrich Karl** (German personal name): see under Frederick Charles.

**Friedrich Wilhelm** (German personal name): see under Frederick William.

**Friedrichshafen**, city, Baden-Württemberg Land (state), southwestern Germany, on the north shore of Lake Constance (Bodensee). It was formed in 1811 by Frederick I of Württemberg through unification of the former free imperial city (1275–1802) of Buchhorn and the monastery and village of Hofen. Hofen (from 1050 a Benedictine convent) became a provostship of monks in 1420, was suppressed in 1802, and passed to Württemberg in 1805. Buchhorn was assigned to Württemberg in 1810.

Before World War II, in which the town was heavily damaged, Zeppelin airships were built there, and it now has a Zeppelin museum. Largely reconstructed, it is a lake resort with an annual fair and ferry connections to Switzerland. Industries include ship and railroad car repair, leatherworking, and the manufacture of cars, textiles, and electrical machinery. Pop. (1989 est.) 52,295.

**Friel, Brian** (b. Jan. 9, 1929, near Omagh, County Tyrone, N.Ire.), playwright noted for his portrayals of Irish Catholic conditions, in both Ireland and Northern Ireland.

Educated at St. Patrick's College, Maynooth (B.A., 1948), and St. Joseph's Training College, Belfast (1949–50), he taught school in Londonderry for 10 years. After *The New Yorker* began regular publication of his stories, he turned to writing full time in 1960, issu-

ing short stories and radio and stage plays. After a six-month tutelage at the Tyrone Guthrie Theatre in Minneapolis, Minn., U.S., in 1963, he wrote his first dramatic success, *Philadelphia, Here I Come!*, produced first by the Dublin Theatre Festival (1964) and subsequently appearing in New York City and London to critical and popular acclaim. The play told of a young Irishman's mood changes in contemplating emigrating from Ireland to America. Soon, Friel himself was settled in County Donegal, Ireland.

Thereafter he had plays produced almost yearly for the next decade. After writing *The Loves of Cass McGuire* (1966), *Lovers* (1967), *Crystal and Fox* (1968), and *The Mundy Scheme* (1969), he turned more to political themes, relating the dilemmas of Irish life and the troubles in Northern Ireland in such plays as *The Freedom of the City* (1973), *Volunteers* (1975), *Living Quarters* (1977), and *Making History* (1988). Many of his plays—notably *Aristocrats* (1979) and *Translations* (1980)—deal with family ties and with mythmaking as a human need.

**Friendly Islands** (Pacific Ocean): see Tonga.

**friendly society**, mutual-aid organization formed voluntarily by individuals to protect members against debts incurred through illness, death, or old age. Friendly societies arose in the 17th and 18th centuries and were most numerous in the 19th century. They had their origins in the burial societies of ancient Greek and Roman artisans. In the Middle Ages the guilds of Europe and England extended the idea of mutual assistance to other circumstances of distress, such as illness.

The friendly societies went a step further by attempting to define the magnitude of the risk against which it was intended to provide and how much the members should contribute to meet that risk. Offshoots of the friendly societies include trade unions, fraternal orders (such as the International Order of Odd Fellows), and life insurance companies.

**Friends, Society of**, also called FRIENDS CHURCH, byname QUAKERS, Christian group that arose in the mid-17th century in England and the American colonies, advocating direct inward apprehension of God without creeds, clergy, or other ecclesiastical forms.

A brief treatment of the Society of Friends follows. For full treatment, see MACROPAEDIA: Protestantism.

Quakerism represents the extreme left wing of the 17th-century English Puritan movement. The three chief emphases of its founder, George Fox (1624–91), were the immediacy of Christ's teaching and guidance, the consequent irrelevance of special buildings or ordained ministers, and the application of Christ's teaching to the whole of life. The early Quakers gathered for worship without liturgy or prearrangement of any kind, or any appointed preacher, believing that out of an energetic and expectant silence God might use any one of the worshippers as a minister.

The rapid spread of Quakerism in the north of England was followed by a vigorous expansive movement to London and the rest of England, to Scotland and Ireland, to the continent of Europe, and to North America. The main centres of Quaker missionary activity in the New World were New England, New Amsterdam and Long Island, Maryland, Virginia, and the West Indies. Almost everywhere they went, the Quakers met with persecution for what were considered unconventional Christian practices. Although the Toleration Act (1689) brought an end to the worst violence of

persecution in Great Britain, many disabilities long remained.

During the 18th century, Quaker thought felt the influence of two conflicting tendencies. Quietism, on the one hand, advocated passivity and self-abnegation in deference to divine direction, while the energy and theology of Wesleyanism and other evangelical movements inspired a new fervour. This tension precipitated several separations within Quakerism in the 18th and 19th centuries, most notably in the United States, where followers of Elias Hicks established a number of regional meetings. With the adoption of revivalist methods, of a worship pattern with hymns and set sermons, and of paid pastors, it was inevitable that opposition by traditionalist Friends should lead to further divisions. By the beginning of the 20th century there were thus (1) a group of "orthodox" or evangelical yearly meetings in fellowship, (2) a group of "conservative" yearly meetings in fellowship following the traditional Quaker patterns of worship, speech, and dress, and (3) a group of Hicksite yearly meetings, rigorously separated from all other Quaker groups for 70 years, increasingly interested in "modern thought" and suspected by other groups of being Unitarian in theology. During and after World War I the barriers of suspicion were broken down and cooperation and reunion among different branches ensued.

The Quaker system of church government has remained substantially unaltered since the time of George Fox. The principal unit is the monthly meeting, a body usually meeting once a month and responsible for all matters of membership, for finance and property, and for deliberation on concerns raised by individual members or referred to it by superior meetings. The extreme austerity characteristic of early Quaker worship services has been modified in many areas with the adoption of hymn singing, set prayers, and prepared sermons. Almost alone among Christian bodies, Friends have no form of outward observance of the sacraments. They believe in a spiritual baptism and a spiritual communion.

**Friends of Constitutional Government** (Japan): see Rikken Seiyūkai.

**Friends of God**, German *GOTTESFREUNDE*, medieval Christian fellowship that originated during the early part of the 14th century in Basel, Switz., and then spread to Germany and the Netherlands. Primarily a middle-class, democratic lay movement espousing a Christian life of love, piety, devotion, and holiness, the Friends of God presaged the 16th-century Reformation. Some of its leaders, attacking corruption in the Western church and expecting a subsequent intervention of God, were tried and executed for heresy.

**Friends of the Constitution, Society of the:** see Jacobin Club.

**Friends of the Rights of Man and the Citizen, Society of the:** see Cordeliers, Club of the.

**Friends World Committee for Consultation** (FWCC), international organization of the Society of Friends (Quakers) founded at Swarthmore, Pa., in 1937. It promotes visits, conferences, and study groups among Friends from all parts of the world and maintains contact with various Friends organizations and activities. It is concerned with the work of the United Nations and has a Friends representative to the United Nations in New York City and in Geneva.

Representatives to the FWCC are appointed by the various Friends yearly meetings and other Friends organizations. Meetings are held every three years. It produces several publications, including the *Friends World News*, issued three times a year. The central FWCC office is in Birmingham, Eng.; the European

office is in Edinburgh; and American offices are in Philadelphia and Plainfield, Ind.

**Fries, Elias (Magnus)** (b. Aug. 15, 1794, Femsjö, Swed.—d. Feb. 8, 1878, Uppsala), Swedish botanist, developer of the first system used to classify fungi.

Fries received his Ph.D. from the University of Lund in 1811 and was appointed as a science lecturer there. Later he was appointed professor and demonstrator in botany but left to accept a professorship at the University of Uppsala, from which he retired in 1859 to study fungi.

During his stay at Lund, Fries had begun to collect and describe known species for his *Systema Mycologicum*, 3 vol. (1821–32), in which he introduced a new system for classifying fungi. With the exception of a few changes with respect to microscopic discoveries, the system is still valid for many groups of fungi.

Fries also developed a system for classifying lichens based on the characters of the organs that produce fruit. This system, presented in his *Lichenographia Europaea Reformata* (1831), was widely accepted until the use of the microscope revolutionized knowledge in

Elias Fries

By courtesy of the Kungliga Biblioteket, Stockholm

this field. Fries was the first person to distinguish between lichens with external coverings on the fruit and those without.

**Fries, Jakob Friedrich** (b. Aug. 23, 1773, Barby, Saxony [Germany]—d. Aug. 10, 1843, Jena, Thuringia [Germany]), German philosopher.

Fries studied at Leipzig and at Jena, and he became professor of philosophy and elementary mathematics at Heidelberg in 1805. His attitude toward contemporary philosophies is set forth in *Reinhold, Fichte und Schelling* (1803; reprinted 1824 as *Polemische Schriften* ["Polemical Writings"]), *System der Philosophie als evidente Wissenschaft* (1804; "System of Philosophy as Intuitive Science"), and *Wissen, Glaube und Ahndung* (1805; "Knowledge, Belief, and Superstition"). His important *Neue oder anthropologische Kritik der Vernunft*, 3 vol. (1807; "New or Anthropological Critique of Reason") attempted to give a new foundation of psychological analysis to the critical theory of Immanuel Kant, which he sought to reconcile with the philosophy of F.H. Jacobi. His *System der Logik* ("System of Logic") appeared in 1811. In 1816 Fries accepted the chair of theoretical philosophy at Jena, but because of his liberal, nationalist views, he was deprived of his professorship. In 1824 he was recalled to Jena as professor of mathematics and physics, and in 1838 the right of public lecturing on philosophy was restored to him.

Among the most important works of his Jena professorate were the *System der Metaphysik* (1824; "System of Metaphysics") and *Die Geschichte der Philosophie* (1837–40; "The History of Philosophy").

**Fries-Greene, William** (b. Sept. 7, 1855, Bristol, Gloucestershire, Eng.—d. May 5, 1921, London), British photographer and inventor, sometimes credited with the invention of cinematography.

Fries-Greene constructed a camera for taking a series of photographs on a roll of perforated film moving intermittently behind a shutter, the basic principle of a motion-picture camera. It would appear, however, that the camera was incapable of taking pictures at a sufficient rate for animation, for no successful

Fries-Greene

By courtesy of the Science Museum, London

presentation of moving pictures was given by him, and the credit for a successful cinematographic device must go to Thomas Edison.

Fries-Greene later pioneered stereoscopic and colour cinematography but lacked the technical knowledge necessary to bring his ideas to fruition.

**BIBLIOGRAPHY.** A biography by Ray Allister (pseud. for Muriel Forth), *Fries-Greene: Close-up of an Inventor* (1948, reprinted 1972), includes photographs from the 1951 film *The Magic Box*, based on this book.

**Friesland**, coastal *provincie*, northern Netherlands, extending inland from the IJsselmeer and the North Sea (west and north) and including four of the West Frisian Islands (see Frisian Islands) off the north coast. The province is drained by a vast system of canals, waterways, and lakes, particularly in the north and west; the principal lakes are Tjeukemeer, Slotermeer, Fluessen, and Sneekermeer. Its area is 1,295 square miles (3,353 square km), rarely exceeding 50 feet (15 m) above sea level, and the population density is less than half the national average. The predominantly Protestant Frisians have maintained both their own language and their own literature to a considerable degree.

The terrain in the southeast, supporting woodlands, orchards, and Frisian cattle, is sandy heathland bordered by fens; some reclamation of peat areas continues. Between fen and coast stretch almost flat clay marshlands and polders, where reclamation continues slowly, chiefly near the north coast. The last serious flooding was in 1825. These lands support potatoes, wheat, sugar beets, and pasture for the Frisian cattle. Agriculture is the basis of the provincial economy; beef and dairy products are sold in large quantities. There is some manufacturing of agricultural machinery in the province, and tourism, largely based on water sports, is an economic asset.

Leeuwarden, the capital, is the only large town, and Harlingen, the only port, serves as its outlet. Other centres are Sneek, Heerenveen, Drachten, Bolsward, Franeker, and Dokkum. There is a nature reserve for seals that is located on the Frisian island of Terschelling. For history, see Frisia. Pop. (1988 est.) 599,104.

**Fries's Rebellion** (1799), uprising, in opposition to a direct federal property tax, by farmers in eastern Pennsylvania led by John Fries (c. 1750–1818). In July of 1798, the Federalist-controlled U.S. Congress, which greatly needed revenues for an anticipated war with France, had voted a direct federal tax on all

real property, including land, buildings, and slaves. This tax, which caused widespread national resentment against the John Adams administration, infuriated the German farmers of Bucks, Northampton, and Montgomery counties in Pennsylvania. Eventually, several hundred farmers took up arms under the leadership of John Fries. At Bethlehem, Pa., Fries and his men forced, by intimidation rather than by actual violence, the release of a group of tax resisters who had been imprisoned under the custody of the federal marshal.

In response, President Adams called out a group of federal troops and militia, who marched into the rebellious counties and began making wholesale arrests of the insurgents. John Fries was captured and subsequently tried twice, convicted of treason on each occasion, and sentenced to hang. He was pardoned by Adams in April 1800, when the president declared a general amnesty for all those who had been involved in the "rebellion."

**frieze**, in Greco-Roman classical architecture, the middle of the three main divisions of an entablature (section resting on the capital). The frieze is above the architrave and below the cornice. The term also refers to any long, narrow, horizontal panel or band used for decorative purposes—*e.g.*, on pottery, on the walls of a room, or on the exterior walls of buildings.

The frieze in buildings using the classical Doric order (*see order*) is usually composed of alternate triglyphs (projecting rectangular blocks, each ornamented with three vertical channels) and metopes (spaces). In buildings using the Ionic, Corinthian, or Composite orders, the frieze is ornamented with relief figures, as in the treasury of the Cnidians at Delphi (early 5th century BC) or the choragic monument of Lysicrates at Athens (310 BC). In Roman buildings the frieze is decorated with plant motifs such as anthemions, acanthus foliage, or garlands. In late Roman and in many Renaissance structures the profile of the frieze is a convex curve and is known as a pulvinated frieze.

The most famous of decorative friezes is undoubtedly that carved on the top of the outer wall of the cella of the Parthenon, just under the ceiling of the portico. This frieze, which is 40 inches (101 cm) high and 525 feet (160 m) long, bears a representation of the ritual procession of the Panathenaic festival and is characterized by superb rhythmic design and

faultless execution. It is a perfect expression of Greek sculpture of the mid-5th century BC and is the most famous example of classical architectural sculpture.

**frigate**, either of two different types of warships, of the 17th through the 19th centuries and of World War II and after.

The Seven Years' War (1756–63) marked the definite adoption of the term frigate for a class of vessel that was smaller than the three-decked ship but was still capable of considerable firepower. A frigate was a three-masted, fully rigged vessel, with its armament carried on a single gun deck and with additional guns on the poop and forecabin. The number of guns varied between 24 and 56, but 30 to 40 guns were common. Frigates could not stand up to ships of the line in fleet engagements, but, sailing at greater speed, they served as scouts or as escorts protecting merchant convoys from privateers and enemy raiders; they also cruised the seas as merchant raiders themselves. With the transition from sail to steam the term frigate gradually gave way to cruiser.

During World War II, Great Britain revived the name frigate by assigning it to a small escort ship used to guard convoys from submarines.

Battle between the frigates HMS *Shannon* and USS *Chesapeake* off Boston during the War of 1812; detail of a lithograph by J.C. Schetky

The National Maritime Museum, London

This vessel displaced about 1,500 tons, was capable of 20 knots, and was equipped with asdic, or sonar, and depth charges. In the postwar decades, the frigate also adopted an anti-aircraft role, adding radar and surface-to-air missiles to its antisubmarine gear. Many frigates now carry helicopters to aid in submarine hunting. Such a vessel displaces upward of 3,000 tons, has a top speed of 30 knots or more and carries a crew of about 200.

For three decades after World War II, the U.S. Navy applied the term frigate to a type of escort ship that was somewhat larger than a destroyer. In 1975 these ships were reclassified as cruisers and destroyers, and the United States then used frigate in the same sense as most other navies.

**frigate bird**, also called MAN-O'-WAR BIRD, any member of five species of large seabirds

Great frigate bird (*Fregata minor*)

Jen and Des Bartlett—Bruce Coleman Inc./EB Inc.

constituting the family *Fregatidae* (order *Pelecaniformes*). Frigate birds are about the size of a hen and have extremely long, slender wings, the span of which may reach to about 2.3 m (nearly 8 feet), and a long, deeply forked tail. In general, adult males are all black, and adult females are marked with white below. The birds have a bare-skinned throat pouch, which in courting males becomes bright red and is inflated, for display purposes, to the size of a person's head. Other distinguishing characteristics are the almost helpless tiny feet with four webbed toes, and a long hooked bill that is used in attacking and robbing other seabirds of their fish.

The frigate bird is perhaps the most aerial of all birds except the swift and alights only to sleep or to tend its nest. The adult, with insufficient preening oil to waterproof its plumage, never willingly alights on the water, but it is unbelievably fast and skillful in the air, soaring effortlessly and often diving to recover falling fish dropped aloft by panic-stricken boobies or other seabirds. It also courses low over the water to seize fish.

Found throughout the world along tropical and semitropical coasts and islands, the frigate bird usually keeps within 100 miles (160 km) of land, to which it must return to roost. It breeds in crowded colonies on islands. Both parents incubate the single white egg.

The largest species (to about 115 cm [45 inches]) is the magnificent frigate bird, *Fregata magnificens*, found on both coasts of America, the Caribbean Sea, and Cape Verde. The great and lesser frigate birds, *F. minor* and *F. ariel*, breed on islands worldwide.

**Frigg**, also called **FRIJA**, in Norse mythology, the wife of Odin and mother of Balder. She was a promoter of marriage and of fertility. In Icelandic stories, she tried to save her son's life but failed. Some myths depict her as the weeping and loving mother, while others stress her loose morals. Frigg was known also to other Germanic peoples, as *Frija* (in German) and *Frea*; her name survives in English in the word *Friday*.

**frigidity**, in psychology, the inability of a woman to attain orgasm during sexual intercourse. In popular, nonmedical usage the word has been used traditionally to describe a variety of behaviours, ranging from general coldness of manner or lack of interest in physical affection to aversion to the act of sexual intercourse. Because of the derogatory connotations that have become

Ionic order frieze, east facade of the Temple of Athena Nike, the Acropolis, Athens, designed by Mnesicles, 5th century BC

By courtesy of the Deutsches Archäologisches Institut, Athens

associated with the term frigidity, it has been replaced in the vocabulary of sex therapists by the general term hypogynism, the inability of a woman to obtain sexual satisfaction under other otherwise appropriate circumstances.

The lay term frigidity encompasses three distinct problems recognized by sex therapists: inability to experience a sexual response of any kind; ability to achieve sexual arousal only with great difficulty (hyposexuality); and the inability to achieve orgasm (anorgasmia). Failure of sexual response in females—as in males—may have specific physical sources; such is the case of women who experience vaginal spasms (vaginismus) or pain (dyspareunia) during attempted intercourse. Likewise, female sexual response may be impaired by purely psychological causes, triggered by emotional conflicts outside the sexual relationship or by anxiety and other stresses within the relationship. *See also* sexual dysfunction.

**Friis, Johan** (b. Feb. 20, 1494, Lundbygaard, Swed.—d. Dec. 5, 1570, Koge, Den.), Danish statesman who, as chancellor under Christian III, king of Denmark and Norway, helped to establish the Lutheran Church as the state church in Denmark and to reform the state and local administrations.

Friis served as secretary at the court of King Frederick I and became successor-designate to the chancellor. When a civil war (the Count's War; 1533–36) broke out over the succession to the throne following Frederick's death (1533), Friis tried to persuade the nobles of

Friis, detail from an oil painting by Jakob Binck, 1551

By courtesy of the Nationalhistoriske Museum på Frederiksborg, Denmark

Fyn province to join their Jutland colleagues in supporting the claims of Frederick's eldest son, Christian III. He was taken prisoner by forces supporting the deposed (1523) king Christian II but escaped and rejoined Christian III in 1535.

After Christian III's assumption of power in 1536, Friis became the King's principal adviser, helping to carry out his religious and administrative reforms. Friis directly supervised the confiscation of Catholic church property, which helped Christian reduce his war debt.

The growing influence of Friis and the Rigsråd (state council) caused the King to declare war on the emperor Charles V (who wanted to place the daughters of Christian II on the Scandinavian thrones). The war was resolved by the Diet of Speyer (1544), a settlement favourable to Denmark. Friis also overcame objections of the Holstein nobility in 1544 when he divided Schleswig and Holstein among the King and his younger brothers.

Friis inspired Danish nobles to enter careers of public service and was also a great patron of the arts. He sponsored continuation and translation of the work of the 12th- and 13th-century Danish historian Saxo Grammaticus and introduced Renaissance architecture to Denmark in the building of his own houses. He was disappointed by the outbreak of the Seven Years' War of the North (1563), believing that war could have been avoided if his advice to Christian III and to Christian's

successor, Frederick II, to assert Danish power in Scandinavia had been heeded.

**frilled lizard:** *see* Chlamydosaurus.

**Friml, (Charles) Rudolf** (b. Dec. 7, 1879, Prague—d. Nov. 12, 1972, Hollywood), U.S.

Rudolf Friml, c. 1932

The Granger Collection, New York City

composer of operettas showing strong European musical influences and suggesting pre-World War I European lightheartedness.

After study under the Czech composer Antonín Dvořák at the Prague Conservatory, Friml served as piano accompanist for the violinist Jan Kubelík in Europe and the United States, where he remained from 1906. In 1912 he was hired to replace Victor Herbert as composer of an operetta proposed for the singer Emma Trentini. The result, *The Firefly* (book and lyrics by Otto Harbach), was highly successful. In the 1920s Friml achieved his greatest popularity. *Rose Marie* (1924; book and lyrics by Harbach and Oscar Hammerstein II), best remembered for the song "Indian Love Call," was followed in 1925 by *The Vagabond King* (book and lyrics by Brian Hooker and W.H. Post), with its popular songs "Only a Rose" and "Some Day," and in 1928 by *The Three Musketeers* (book and lyrics by Clifford Grey and P.G. Wodehouse). From 1934 Friml composed for motion pictures. His last important song, "The Donkey Serenade" (composed with Herbert Stothart; words by Chet Forrest and Bob White), was interpolated into a film version (1937) of *The Firefly*.

**fringe, interference** (physics): *see* interference fringe.

**fringe benefit**, any nonwage payment or benefit (e.g., pension plans, profit-sharing programs, vacation pay, and company-paid life, health, and unemployment insurance programs) granted to employees by employers. They may be required by law, granted unilaterally by employers, or obtained through collective bargaining. Employers' payments for fringe benefits are included in employee-compensation costs and therefore are not usually liable to corporate income tax. If the cost of fringe benefits were paid directly as wages, the worker would pay personal income tax on this amount and therefore have less to spend on such benefits as he might elect to furnish for himself. Thus, the employer can obtain more benefits for the employee with the same amount of money. He can also take advantage of lower group rates for insurance.

Fringe benefits have generally constituted a higher proportion of total employee compensation in Europe than in the United States. In Europe they are most often the result of legislation, whereas in the United States collective bargaining has been more important in gaining such benefits for workers. The prevalence of fringe-benefit programs increased sharply during World War II because controls on this type of compensation were less stringent than controls on wages.

**fringe moss**, any of the plants of the genus *Grimmia* (order Bryales), which includes sev-

eral hundred species distributed throughout the world, primarily on rocks or stone walls. A few species grow on roofs or in streams; *G. maritima* forms cushions up to four centimetres (1½ inches) tall on rocks along seashores. Nearly 50 species of *Grimmia* are native to North America, and about 30 are found in Great Britain. Most fringe mosses are one to three centimetres tall and have blackish-green, lance-shaped phyllids (leaves) about two millimetres (¼ inch) long, which are sometimes tipped with a white hair.

**fringe tree**, either of two tree species constituting the genus *Chionanthus* in the family Oleaceae. They get their name from the long, fringed, snow-white flowers that cover the trees in spring. The flowers hang in clusters of about the same length as the leaves and have four narrow petals.

The dark-blue fruits are oval. *C. virginicus*, from southeastern North America, reaches

Fringe tree (*Chionanthus virginicus*)

Gilbert L. Twiest

about 10 metres (33 feet). *C. retusus*, from China, seldom reaches 6 m.

**Fringillidae**, songbird family, order Passeriformes, sometimes collectively termed New World seedeaters. The group includes grosbeaks, cardinals, longspurs, Galápagos finches, New World sparrows, and Old World buntings. The relationships of seed-eating birds are the subject of great disagreement, many authorities preferring to place certain of these groups in the family Emberizidae (*q.v.*), with a somewhat different family composition.

**fringing reef**, a coral reef (*q.v.*) consisting of a sea-level flat built out from the shore of an island or continent.

**Frio, Cape**, Portuguese CABO FRIO, promontory on Brazil's southeast Atlantic coast, Rio de Janeiro state, 70 mi (113 km) east of the city of Rio de Janeiro. Discovered in 1503 by Amerigo Vespucci, the cape became a 16th-century pirate stronghold and now is the site of the towns of Cabo Frio and Arraial do Cabo. The cape attracts tourists for its good weather and the nearby São Mateus Fort, built by the French.

**Frioul, Géraud-Christophe-Michel Duroc, duc de** (duke of): *see* Duroc, Géraud-Christophe-Michel.

**Frisch, Frank**, byname of FRANK FRANCIS FRISCH, also called THE FORDHAM FLASH (b. Sept. 9, 1898, Queens, New York City—d. March 12, 1973, Wilmington, Del., U.S.), U.S. professional National League baseball player and manager, who played in 50 World Series games and was on four pennant winners with the New York Giants (1919–26) and four with the St. Louis Cardinals (1927–37).

Frisch played baseball, football, and basketball at Fordham University (New York City) and after graduating went directly to the Giants in 1919. He played the infield, mainly at second base, through the 1926 season and was then traded to the St. Louis Cardinals, where

he played at second and third base through the 1937 season and also managed (1933–38). He hit for an average of .300 or more in 13 of his 19 seasons. He was a switch hitter (batting right- and left-handed) and a very good base runner. He threw right-handed. He led the league in stolen bases for three seasons (1921 [49], 1927 [48], 1931 [28]). His career batting average was .316. He later managed the Pittsburgh Pirates (1940–46) and the Chicago Cubs (1949–51). He was a radio sports broadcaster in the 1940s and a radio and television broadcaster in New York City in the 1950s. He was voted into the Baseball Hall of Fame in 1947.

**Frisch, Karl von** (b. Nov. 20, 1886, Vienna, Austria—d. June 12, 1982, Munich, W.Ger.), zoologist whose studies of communication among bees added significantly to the knowledge of the chemical and visual sensors of insects. He shared the 1973 Nobel Prize for Physiology or Medicine with animal behaviourists Konrad Lorenz and Nikolaas Tinbergen.

Frisch received a Ph.D. from the University of Munich in 1910. He was appointed director of the Zoological Institution of the University of Rostock in 1921, and in 1923 he accepted a similar position at the University of Breslau. In 1925 Frisch returned to the University of Munich, where he established the Zoological Institution. When this institution was destroyed during World War II, he joined the staff of the University of Graz in Austria, but he returned to Munich in 1950, remaining there until his retirement in 1958.

About 1910 Frisch initiated a study that proved fishes could distinguish colour and brightness differences. He also later proved that auditory acuity and sound-distinguishing ability in fishes is superior to that in humans.

Frisch is best known for his studies of bees, however. In 1919 he demonstrated that they can be trained to distinguish between various tastes and odours. He found that while their sense of smell is similar to that of humans, their sense of taste is not as highly developed. He also observed that it is not limited to the quality of sweetness. He found that bees communicate the distance and direction of a food supply to other members of the colony by two types of rhythmic movements or dances: circling and wagging. The circling dance indicates that food is within 75 m (about 250 feet) of the hive, while the wagging dance indicates a greater distance.

In 1949 Frisch established that bees, through their perception of polarized light, use the Sun as a compass. He also found that they are capable of using this method of orientation when the Sun is not visible, apparently remembering patterns of polarization presented by the sky at different times of the day and the location of previously encountered landmarks.

**Frisch, Max (Rudolf)** (b. May 15, 1911, Zürich, Switz.—d. April 4, 1991, Zürich), German-Swiss dramatist and novelist, noted for his Expressionist depictions of the moral dilemmas of 20th-century life.

In 1933 Frisch withdrew from the University of Zürich, where he had studied German literature, and became a newspaper correspondent. After touring southern and eastern Europe from 1934 to 1936, he returned to Zürich, where he studied architecture. Frisch worked as an architect after service in the Swiss army during World War II. He abandoned architecture in 1955 to devote himself full-time to writing.

Frisch's play *Santa Cruz* (first performed 1946) established the central theme found throughout his subsequent works: the predicament of the complicated, skeptical individual

in modern society. One of Frisch's earliest dramas is the morality play *Nun singen sie wieder* (1945; "Now They Sing Again"), in which Surrealistic tableaux reveal the effects caused by hostages being assassinated by German Nazis. His other historical melodramas include *Die chinesische Mauer* (1946; *The Chinese Wall*) and the bleak *Als der Krieg zu Ende war* (1949; "When the War Was Over"). Reality and dream are used to depict the terrorist fantasies of a responsible government prosecutor in *Graf Oederland* (1951; *Count Oederland*), while *Don Juan oder die Liebe zur Geometrie* (1953; *Don Juan, or The Love of Geometry*) is a reinterpretation of the legend of the famous lover of that name. In his powerful parable play *Biedermann und die Brandstifter* (1958; *The Firebugs*), arsonists invade the house of the self-righteous philistine Biedermann, who allows them to burn his world rather than reveal his real self. Frisch's later plays include *Andorra* (1962), about the destructiveness of anti-Semitic prejudice, and *Biografie* (published 1967; *Biography*), which deals with social relationships and their limitations.

Frisch's novels *Stiller* (1954; *I'm Not Stiller*), *Homo Faber* (1957), and *Mein Name sei Gantenbein* (1964; *A Wilderness of Mirrors*) are concerned with the uncertainties of modern intellectuals and the utter failure confronting those desiring to change their identity or pattern of living. His autobiographical works include two diaries, *Tagebuch 1946–1949* (1965; *Sketchbook 1946–1949*) and *Tagebuch 1966–1971* (1972; *Sketchbook 1966–1971*). His later novels include *Montauk: Eine Erzählung* (1975) and *Der Mensch erscheint im Holozän* (1979; *Man in the Holocene*).

**Frisch, Otto Robert** (b. Oct. 1, 1904, Vienna, Austria—d. Sept. 22, 1979, Cambridge, Cambridgeshire, Eng.), physicist who, with his aunt Lise Meitner, described the division of neutron-bombarded uranium into lighter elements and named the process fission (1939). At the time, Meitner was working in Stockholm and Frisch at Copenhagen under Niels Bohr, who brought their observation to the attention of Albert Einstein and others in the United States.

After receiving his doctorate at Vienna (1926), Frisch, with Otto Stern and Immanuel Estermann, measured the magnetic moment of the proton (1933). During World War II he was engaged in atomic research at Los Alamos, N.M. From 1947 he taught at Cambridge and directed the nuclear physics department of the Cavendish Laboratory. His books include *Atomic Physics Today* (1961).

**Frisch, Ragnar (Anton Kittil)** (b. March 1895, Oslo, Nor.—d. Jan. 31, 1973, Oslo), pioneer Norwegian econometrician and economist who was a joint winner (with Jan Tinbergen) of the 1969 Nobel Prize for Economics.

Frisch was educated at the University of Oslo, obtaining his Ph.D. in 1926. He was appointed to a specially created professorship at Oslo in 1931, a post he held until his retirement in 1965. Frisch was a pioneer of econometrics—the application of mathematical models in association with statistical techniques to economic data—and is credited with inventing the term. He was one of the founders of the Econometric Society and, for 21 years, editor of *Econometrica*.

Frisch is particularly famous for the development of large-scale econometric modeling linked to economic planning and national income accounting. In this connection he was also influential in the introduction of academically trained economists into key civil service positions. Frisch was involved with a range of macroeconomic topics, including the trade cycle, production theory, consumer behaviour, and statistical theory. Many of the papers he published are regarded as classics.

**Frischlin, Philipp Nikodemus** (b. Sept. 22, 1547, Balingen, Württemberg [Germany]—d. Nov. 29/30, 1590, Hohenurach, near Reutlingen [Germany]), German philologist, poet, and commentator on Virgil. He was one of the last of the Renaissance humanists.

Frischlin was educated at the University of Tübingen, where he became (1568) professor of poetry and history. In 1575, for his comedy *Rebecca*, which he read at Regensburg before the Holy Roman emperor Maximilian II, he was rewarded with the laureateship, and in 1577 he was made a count palatine.

In 1582 Frischlin had to leave Tübingen, and he spent two years teaching at Laibach. Shortly after his return to Tübingen in 1585, he was threatened with a criminal prosecution for immoral conduct and fled to Frankfurt am Main (1587). For 18 months he taught in Brunswick, and he appears also to have lived at Strasbourg, Marburg, and Mainz. From Mainz he wrote libelous letters, which led to his arrest in March 1590. He was imprisoned in the fortress of Hohenurach, where, on the night of Nov. 29–30, 1590, he was killed in a fall while attempting to let himself down from the window of his cell.

In his Latin verse Frischlin often successfully imitated classical models. His Latin comedies have freshness and vivacity, and his commentaries on Virgil's *Georgics* and *Bucolics* were important contributions to the scholarship of his time. He also wrote plays in German.

**Frisco** (U.S.): see San Francisco.

**Frisco, The:** see Saint Louis-San Francisco Railway Company.

**Frisi, Paolo** (b. April 13, 1728, Milan, Austrian Habsburg domain [Italy]—d. Nov. 22, 1784, Milan), Italian mathematician, astronomer, and physicist who is best known for his work in hydraulics. His most significant contributions to science, however, were in the compilation, interpretation, and dissemination of the work of other scientists.

Frisi was a member of the Barnabite religious order, a professor at the University of Milan, and a member of most of the major scientific societies of his time. He was held in such esteem by his contemporaries that plans for nearly all the major hydraulic works constructed in northern Italy during his adult life were first shown to him for his inspection. His major work on hydraulics, *Del modo di regolare i fiumi, e i torrenti* (1762; *A Treatise on Rivers and Torrents*), a summary of the best information in this field, was widely used as an engineering handbook. The commentaries he wrote on the work of such scientists as Galileo Galilei and Sir Isaac Newton were influential in bringing their ideas to the attention of a wide audience.

**Frisia**, historic region of The Netherlands and Germany fronting the North Sea and including the Frisian Islands. It has been divided since 1815 into Friesland, a province of The Netherlands, and the Ostfriesland and Nordfriesland regions of northwestern Germany. Frisia is the traditional homeland of the Frisians, a Germanic people who speak a language closely related to English.

In prehistoric times of uncertain date, the tribal Frisians migrated to the North Sea coastal region between the mouth of the Rhine River (at Katwijk, north of The Hague) and the mouth of the Ems River and ousted the resident Celts. Much of their land was then covered by lakes and estuaries and was exposed to the incursions of the sea, so the inhabitants lived mostly on man-made mounds called terps. Slowly, as the shifting of the waters allowed, they brought the lower-lying land under cultivation and protected themselves against the sea by building more terps (dikes were not practicable). Most of these were in the modern provinces of Friesland and Groningen.

From the 1st to the 5th century AD, the Frisians were more or less tributary to the Romans. Frisia was then infiltrated by Angles and Saxons on their way to England and was subsequently conquered by the Franks under Charlemagne, who converted the Frisians to Christianity. In subsequent centuries their territory became divided into the following regions: West Frisia, extending from the mouth of the Rhine River to the Vlie River and what is now the Zuiderzee; Middle Frisia, extending from the Vlie eastward to the town of Leeuwarden; and East Frisia, extending from Leeuwarden eastward to the estuary of the Jade River. West Frisia came under the control of the counts of Holland by 1250. Part of East Frisia came to be dominated by the city of Groningen (which was ruled by the bishop of Utrecht), and part was a county under the Cirksena family from 1454 to 1744, when it passed to the kingdom of Prussia. Middle Frisia kept itself free of overlords, however, until the end of the Middle Ages. Feudalism never took root there, hence the adage "Every Frisian is a nobleman." Rejecting foreign interference, the Frisians governed themselves with a degree of liberty that is rare in medieval Europe. In 1524, however, Middle Frisia fell to the Holy Roman emperor Charles V, and thenceforth it was joined to the Burgundian portion of the Habsburg heritage. During the Reformation the Frisians became Protestants. Frisia participated in the revolt of the northern Netherlands against Spanish rule, and thus became a province (Friesland) of the republic of the Netherlands, as constituted by the Union of Utrecht (1579).

In modern times the Frisian people have become most famous for their cattle (records from as early as the 1st century BC suggest considerable cattle raising); they also engage in other agriculture. Traditionally, they were also a seafaring and commercial people and had one of the largest textile industries of medieval northwestern Europe. Although the Frisian language appeared for a time to be losing currency, it has experienced a resurgence in recent years; it has been recognized as an official language of The Netherlands and is taught in primary schools throughout the province of Friesland.

**Frisian Islands**, low-lying chain of islands from 3 to 20 miles (5 to 32 km) off the northern European mainland. They extend in an arc from near the port of Den Helder (northern Netherlands), eastward along the Dutch and German coasts as far as the Elbe River,

Coastline of Texel Island near De Slufter in the Frisian Islands

P. R. Johanson—Ostman Agency

and then turn sharply north along the coast of Schleswig-Holstein (Germany) and the southern part of the Jutland Peninsula coast (Denmark). Although they form a single physical feature, it is customary to subdivide them into

the West, East, and North Frisian Islands. After the North Sea established a southwestern outlet to the Atlantic about 7,000–5,000 BC, its southeasterly shore probably coincided with the present curve of the Frisians. Periodic subsidence, storms, and flooding have since produced this long chain of islands separated from the mainland by the narrow belt of shallow waters and tidal mud flats generally called *wadden* in Dutch (German *Watten*).

Not surprisingly, many Frisian legends and folk songs tell of drowned villages. The Dutch and German governments have spent large sums not only to protect their seaward coasts but also to reclaim the land from the *wadden* for farming. Fishing, sheep and cattle raising, and rye, oat, and potato growing are the main occupations in most islands; the sandy beaches and resorts attract many tourists.

The West Frisian Islands (Dutch: Friese Eilanden), belonging to The Netherlands, include from west to east the inhabited islands of Texel, Vlieland, Terschelling, Ameland, and Schiermonnikoog and the virtually uninhabited group of Simonszand, Boschplaat, Rottumerplaat, and Rottumeroog (Rottum). Extending southeast from the coastal dunes, Texel has an extensive area of polder (land previously under water) reclaimed from the Wadden Sea. Very small polder areas also exist in Terschelling, Ameland, and Schiermonnikoog. Eierland in north Texel is partly a nature reserve in which thousands of seabirds nest. Scattered farmsteads with a few villages are typical of the five main islands.

The East Frisian Islands (German: Ostfriesische Inseln) belong to Germany and extend from the Ems River estuary eastward to Jade Channel, the outer part of Jade Bay, with two small islands, Scharhörn and Neuwerk, lying near the estuary of the Elbe River. Smaller than most of the West Frisian group, the main islands from west to east are Borkum, Juist, Norderney, Baltrum, Langeoog, Spiekeroog, and Wangeroog, which have scattered farmsteads and small villages. Scharhörn is uninhabited, whereas Neuwerk has only lighthouse keepers and lifeboat crews. In summer, tourists visit the main islands, and the towns of Nordseebad Borkum and Norderney are popular resorts. Holiday steamers ply the islands' sheltered south coasts, many of which have light railways to carry visitors inland.

The North Frisian Islands (German: Nordfriesische Inseln) are divided between Germany and Denmark. Apart from the rocky red sandstone island of Helgoland that stands aloof both in location and geologically, the North Frisian Islands run from Trischen, north of the Elbe estuary, northward along the coasts of Schleswig-Holstein and the Jutland Peninsula to Fanø, near the Danish port of Esbjerg. Until 1634 the present German islands of Nordstrand, Nordstrandischmoor, and Pellworm were part of one large island. A similar situation exists farther north with the German islands of Hooge, Nordmarsch-Langeness, Amrum, Föhr, and Sylt. Still north of these lie the Danish islands of Rømø, Manø, and, lastly, Fanø. Rømø and Sylt are connected to the mainland by long embankments, and the entire group underwent extensive land reclamation in the 1970s.

**Frisian language**, Frisian *FRIESISCH*, the West Germanic language most closely related to English. Although Frisian was formerly spoken from what is now the province of Noord-Holland (North Holland) in The Netherlands along the North Sea coastal area to modern German Schleswig, including the offshore islands in this area, modern Frisian is spoken in only three small remaining areas, each with its own dialect. These dialects are West Frisian, which is spoken in the province of Friesland in The Netherlands, including the islands of Schiermonnikoog and Terschelling; East Frisian, which is spoken in the Saterland west

of Oldenburg, Ger.; and North Frisian, which is spoken along the west coast of Schleswig in Germany and on the offshore islands of Sylt, Föhr, Amrum, the Halligen Islands, and Helgoland.

Written records date from the end of the 13th century and are in Old Frisian, a stage of the language that lasted until the late 16th century. Old Frisian shows all the features that distinguish English and Frisian from the other Germanic languages.

Although Frisian was hardly used at all as a written language for about 300 years after the end of the Old Frisian period, there has been a revival in modern times in the West Frisian area. The language is now used in the schools and courts in the province of Friesland and is acknowledged as an official language by the government of The Netherlands. There is also a Frisian Academy. East and North Frisian are being gradually supplanted by German.

**Frisian literature**, the literature that is written in West Frisian, a language closely related to Old English, and now spoken primarily by the inhabitants of Friesland, a northern province of The Netherlands. (The languages known as East Frisian and North Frisian made little contribution to Frisian literature. See Frisian language.)

Frisian literature, as it is known today, began with Gysbert Japicx (also spelled Japiks; 1603–66) in the 17th century. Friesland's incorporation into the Dutch Republic in 1581 threatened to reduce Frisian to a mere peasant dialect. Japicx, however, through his *Friesche Rymlere* (1668; "Frisian Verse") and other works proved the richness and versatility of the language and saved it from potential extinction.

It was not until the Romantic period of the 19th century, however, that Frisian literature began to flourish as a national literature. About this time the Halbertsma brothers—Eeltsje, Joast, and Tsjalling—founded a movement known as "New Frisian Literature," and they went on to write an amusing collection of Romantic prose and poetry, *Rimen en Teltsjes* (1871; "Rhymes and Tales"), that stimulated the rise of a rich folk literature in the second half of the 19th century. Their contemporary, the philologist and poet Harmen Systerma, wrote of the heroic past in old Germanic verse forms.

In 1915 Douwe Kalma launched the Young Frisian Movement, which challenged younger writers to break radically with the provincialism and didacticism of past Frisian literature. This break had been anticipated in the lyrical poetry and fiction of Simke Kloosterman and in the psychological narratives of Reinder Brolsma. Kalma himself made important contributions to poetry, drama, translation, and literary history and criticism. Other important Frisian literary figures in the first half of the 20th century were the essayist E.B. Folkertsma and the poets Fedde Schurer, Obe Postma, and Douwe Tamminga.

Frisian literature since World War II has largely broken away from the national movement and many traditional conventions, especially through Anne Wadman's leadership as critic, essayist, and novelist. Most Frisian poetry and fiction now reflects the larger western European community of writers in themes and techniques.

**frit fly**, also called *CHLOROPID FLY*, any small fly of the family Chloropidae (order Diptera), destructive to oats, rye, barley, wheat, and other cereal grains. Frit flies, often bright yellow and black, are usually found in grassy areas. The larvae live in developing grain heads and within stems, causing the central leaf to wilt. Some frit flies are carriers of conjunctivitis and yaws. They breed in decaying vegeta-

tion and excrement and feed on pus, blood, and other animal fluids. Because some frit flies (for example, *Hippelates*) are attracted to the eyes, they are called eye gnats.

**Frith, William Powell** (b. Jan. 9, 1819, Aldfield, Yorkshire, Eng.—d. Nov. 2, 1909, London), English painter famous for his crowded scenes of contemporary English life, executed with a preciseness of technique akin to that of the Pre-Raphaelites.

Frith entered the Royal Academy school in 1837, and in 1840 he exhibited there his first picture, "Malvolio Before the Countess Olivia." He quickly gained wide popularity. Elected associate of the Royal Academy in 1845 and a member in 1852, he established his reputation with a succession of large compositions of everyday English life, the first of which, "Ramsgate Sands" (exhibited 1854), was bought by Queen Victoria. His most memorable works of the period include "The Derby Day" (1858) and "The Railway Station" (1862). Frith later turned to moralizing works exemplified by a series of five paintings under the general title "The Race for Wealth" (1880).

**fritillary**, any ornamental plant of the genus *Fritillaria* of the family Liliaceae, consisting of about 80 species of bulbous, mostly perennial

Snake's head (*Fritillaria meleagris*)  
Ingmar Holmasen

herbs, native primarily to the North Temperate Zone. Members of the genus have bell-shaped, nodding flowers that usually are solitary. The leaves alternate along the stem or are in whorls. A nectar gland is present at the base of each of the six parts of the flower.

In many species the flower has a checkered appearance. The fruit is a three-valved capsule with many seeds. Snake's head, or toad lily (*F. meleagris*), a species with poisonous bulbs, and crown imperial (*F. imperialis*), a strong-smelling plant, are commonly cultivated as garden flowers.

**fritter**, any of three types of fried foods. Plain fritters are deep-fried cakes of chow paste or a yeast dough. In a second type bits of meat, seafood, vegetables, or fruit are coated with a batter and deep fried. Small cakes of chopped food in batter, such as corn fritters in the southern United States, are also called fritters.

Fritters are found in many cuisines. The French *beignets*, Italian *bigne*, and Greek *loukoumades* are sweet cakes of the first type of fritter. The batter-frying technique was introduced into Japan by the Portuguese and Spanish in the late 16th century; the tempura that developed, a mixed fry of shrimps, herbs, and vegetables, has been totally incorporated into the cuisine. The Indian *pakora* is a savoury

deep-fried cake containing bits of cauliflower, eggplant, or other vegetables. *Fritto misto* is an Italian dish of bits of meat, seafood, and vegetables dipped in batter and fried in olive oil. A specialty dish of various local cuisines is the flower fritter, using daylilies, roses, violets, acacia, elder blow, and squash blossoms.

**Fritzsche, Hans** (b. 1899, Dresden, Ger.—d. Sept. 27, 1953, Cologne), German journalist and broadcaster, a member of the Nazi propaganda ministry, whose nightly commentaries on Nazi radio throughout World War II climaxed in his broadcast of the news of Hitler's suicide.

After attending the universities of Würzburg and Leipzig, he began practicing law. After World War I he joined the virulently anti-British and jingoistic Young Conservative movement and eventually, in 1929, joined the Nazi Party. He became a member of the *Sturmabteilung* (SA; "Storm Troopers") the following year and served mostly in his native Saxony and in Thuringia.

Fritzsche started broadcasting in September 1932 with a daily program called "Hans Fritzsche Speaks." That same year he was named head of the Wireless News services, a government agency. The agency was incorporated into Joseph Goebbels' propaganda ministry on May 1, 1933, and Fritzsche became head of the press division of the ministry in 1938. By November 1942 he had become chief of the ministry's radio division. Throughout his association with the propaganda ministry Fritzsche was subordinate to Goebbels and had no hand in formulation of policy. Captured in Berlin by Soviet troops in May 1945, he was indicted at Nürnberg but was found not guilty under the terms of the indictment. Shortly after, a German court tried and sentenced him to nine years' imprisonment. He was released in 1950 and died three years later of cancer.

**Friuli-Venezia Giulia**, *regione* of northeastern Italy, bordering Austria to the north, Slovenia to the east, the Adriatic Sea to the south, and the Veneto *regione* to the west; it has an area of 3,030 square miles (7,847 square km) and comprises the *provincias* of Udine, Pordenone, Gorizia, and Trieste. In the north the solid wall of the Carnine Alps, broken only by the Plöcken Pass (Passo di Monte Croce) and the low Tarvisio saddle, form a spectacular backdrop to the Tagliamento River Valley, the heart of Friuli. The southern part of the *regione* is a low coastal plain, some of it occupied by the shallow lagoons of Grado and Caorle. To the southeast, that part of the former Free Territory of Trieste that is now an integral part of Italy extends as a narrow corridor between the Karst (Carso) limestone plateau and the Adriatic Sea, as far as the city of Trieste.

Known in Roman times as the Julian region, the area was divided after the barbarian invasions into a coastal part (dominated by the Byzantines through the city and port of Grado) and an inland zone ruled by the dukes of Friuli and the counts of Gorizia. The rise of the Roman Catholic patriarchate of Aquileia to prominence in the 11th century brought Friuli and the Istrian Peninsula, as well as the seacoast, under the control of this ecclesiastical sovereignty.

The period of Aquileian hegemony ended when Venice became the great power in northeastern Italy (1420) and shared its dominion over the region with Austria (at Gorizia and Trieste). After 1815 all Venezia Giulia and Friuli fell under Habsburg rule, Udine *provincia* (including Pordenone) becoming part of Italy in 1866; the rest of the *regione* (including much of what is now Slovenia and Croatia) was added in 1918. After World War II the Istrian Peninsula, the hinterland of Trieste, and the Karst plateau became part of Yugoslavia, while Trieste and the area surrounding it be-

came a free territory divided into northern and southern (A and B) zones under U.S.-British and Yugoslavian administration, respectively. Udine *provincia* was detached from Veneto and united with Gorizia *provincia* to form Friuli-Venezia Giulia. The London agreement of 1954 restored the city of Trieste and part of A zone to Italy, and the city became the *regione's* capital. A statute of autonomy for the *regione* was passed on Jan. 31, 1963. The *provincia* of Pordenone was formed in 1968.

One of the poorer parts of Italy, the *regione* ranges in terrain from rocky uplands and infertile foothills in the north to arid or marshy lowlands in the south, where reclamation has shown little success and much of the land remains in subsistence farms.

The *regione* is one of Italy's most seismically active, as seen in a May 1976 earthquake centered north of Udine that killed more than 1,000 people. Rainfall in the north (the highest in Italy), however, favours the development of natural meadows for livestock; the ham and dairy products of Friuli are famous. Corn (maize) and some other cereals are grown in the valley of the Tagliamento, and there is market gardening around Udine. The larger cities, Udine, Pordenone, Gorizia, Monfalcone, and Trieste, have all experienced considerable industrial development, and Trieste is one of Italy's great ports, although its trade is smaller than it was before 1914, when it served most of central Europe. The *regione* is connected by rail and road with Austria, Slovenia, Venice, and thence the rest of Italy. A Friulian separatist movement exists and periodically presses its demands for Friulian autonomy. Friulians represent about three-fifths of the *regione's* population. Pop. (2001) 1,183,764.

**Fröbel, Friedrich (Wilhelm August):** see Froebel, Friedrich (Wilhelm August).

**Froben, Johann**, also spelled JOHANNES FROBENIUS (b. c. 1460, Hammelburg, Franconia [Germany]—d. October 1527, Basel, Switz.), the most famous of the Basel scholars, whose professional innovations revolutionized printing in Basel and whose publications included many outstanding works of scholarship.

Froben's first publication, a Latin Bible, appeared in 1491. Entering into partnership with Johann Petri (1496), Johann Amerbach (1500), and the bookseller Wolfgang Lachner, whose daughter Gertrud he married, Froben came to control four presses by 1515 and, later, seven. Froben's contributions to printing in

Froben, engraving by B. Hubner, 1795, after a painting by Hans Holbein the Younger

By courtesy of the Bibliothèque Nationale Suisse, Bern

Basel included popularizing roman type, introducing italic and Greek fonts, experimenting with smaller and cheaper books, and employing talented artists, including Hans Holbein, as illustrators. His correctors included many famous scholars who benefited from the proximity of the hitherto little-used manuscript collections of Alsace and the Palatinate.

About 250 of Froben's publications have

been listed. They include, notably, the first New Testament printed in Greek, with a Latin translation (1516) by Erasmus, who after 1513 entrusted the printing of all his works to Froben, and also the works of the Roman historian Velleius Paterculus (1520) and the Latin church father Tertullian (1521), both edited by Beatus Rhenanus.

**Frobenius, Georg**, in full FERDINAND GEORG FROBENIUS (b. Oct. 26, 1849, Berlin, Prussia [Germany]—d. Aug. 3, 1917, Berlin), German mathematician who made major contributions to group theory, especially the concept of abstract groups and the theory of finite groups of linear substitutions, that later found important uses in the theory of finite groups as it applies to quantum mechanics.

Frobenius became assistant professor of mathematics at the University of Berlin in 1874 and in 1875 was appointed professor of mathematics at the Federal Polytechnic, Zürich. In 1892 he returned to the University of Berlin as professor of mathematics.

Frobenius' findings in abstract group theory were published in the paper "Über Gruppen von vertauschbaren Elementen" (1879; "Concerning Groups of Permutable Elements"), in collaboration with Ludwig Stickelberger. In collaboration with Issai Schur, he developed group theory by means of the theory of finite groups of linear substitutions. Many of his results were published in such papers as "Über die Gruppencharaktere" (1896; "Concerning Group Characters"). He also contributed to the development of a means of solving linear homogenous differential equations.

**Frobenius, Leo (Viktor)** (b. June 29, 1873, Berlin, Ger.—d. Aug. 9, 1938, Biganzolo, Italy), German explorer, ethnologist, and one of the originators of the culture-historical ap-

Leo Frobenius  
Bavaria-Verlag

proach\* to ethnology. He was also a leading authority on prehistoric art.

Largely self-educated as a social scientist, Frobenius led 12 expeditions to Africa between 1904 and 1935 and explored centres of prehistoric art in the Alps, Norway, Spain, and northern and southern Africa. Frobenius attributed a common origin to the cultures of Oceania and West Africa. He advocated the idea of cultural diffusion and arranged areas of the same cultural distribution into what he called *Kulturkreise* (cultural clusters, or cultural complexes). This concept was further extended by Fritz Graebner.

Frobenius began examining the nature of culture in the first volume of his *Probleme der Kultur*, 4 vol. (1899–1901; "Problems of Culture"). Frobenius wrote many articles and pamphlets and 60 books, including *Und Afrika sprach*, 3 vol. (1912–13; *The Voice of Africa*), and *Erlebte Erdteile*, 7 vol. (1925–29; "Parts of the Earth Experienced"). In 1932 he began teaching cultural anthropology at the University of Frankfurt am Main and from 1934 was director of the Municipal Museum of Ethnology, Frankfurt.

**Froberger, Johann Jakob** (b. May 18, 1616, Stuttgart, Württemberg [Germany]—d. May

7, 1667, Héricourt, Fr.), German composer, organist, and harpsichordist whose keyboard compositions are generally acknowledged to be among the richest and most attractive of the early Baroque era.

Froberger became a court organist in Vienna in 1637, but the same year he went to Rome to study under Girolamo Frescobaldi. After further employment at the Viennese court (1641–45 and 1653–57) he toured widely.

Froberger was the earliest important German composer for the harpsichord. His style represents an integration of French, Italian, and other styles with the more austere style of German keyboard music. He was the first German master of the keyboard suite. His suites in manuscript consisted of three movements, often with an interpolated gigue; but in the posthumous publication of 1693 they were arranged in the order that became standard for the suite: allemande, courante, sarabande, and gigue. Although the suites are clearly for harpsichord or clavichord, in other works, such as the partitas, it is difficult to say whether the music was intended for harpsichord or organ. His canzoni for harpsichord and organ are composed in several sections bound together by a single theme. His powerful and imaginative toccatas and fantasias, composed for the organ, show the influence of Frescobaldi and were highly regarded by J.S. Bach.

**Frobisher, Sir Martin** (b. c. 1535, Yorkshire, Eng.—d. Nov. 22, 1594, Plymouth, Devon), English navigator and early explorer of Canada's northeast coast.

Frobisher went on voyages to the Guinea coast of Africa in 1553 and 1554, and during the 1560s he preyed on French shipping in the English Channel under a privateering license from the English crown; he was arrested several times on charges of piracy but never brought to trial.

Having become interested in the possibility of finding a Northwest Passage to the Pacific Ocean, Frobisher in 1576 obtained the command of three small ships, in one of which he succeeded in crossing the Atlantic that year. He reached Labrador and Baffin Island and discovered the bay that now bears his name. He returned to England with reports of possible gold mines, thereby obtaining royal backing for two further expeditions to the same area, in 1577 and 1578. On the latter of these expeditions, Frobisher sailed up Hudson Strait but then turned back to anchor at Frobisher Bay, where his attempts to establish a colony were unsuccessful. Frobisher's single-minded pursuit of mineral treasure limited the exploratory value of his voyages, and, when the ores he brought back from his third voyage proved to contain neither silver nor gold, his financing collapsed, and he was forced to seek other employment.

In 1585 Frobisher sailed as vice admiral of Sir Francis Drake's expedition to the West Indies, and three years later he played a prominent part in the campaign against the Spanish Armada, being knighted during the operations. Over the next six years Frobisher commanded various English naval squadrons, including one in the Azores (1591) that unsuccessfully sought to capture Spanish treasure ships. In 1594 he was mortally wounded fighting a Spanish force on the west coast of France. Frobisher was undoubtedly one of the ablest seamen of his time, but as an explorer he lacked the capacity for patient factual investigation.

**Frobisher Bay**, inlet of the North Atlantic extending northwestward from the southeastern tip of Baffin Island, Canada. The bay is about 150 miles (240 km) long and 20–40 miles (32–64 km) wide and has a maximum depth of 400 feet (120 m). It was discovered in 1576 by Sir Martin Frobisher, who believed it to be a strait. It was identified as a bay in 1860. The town of Iqaluit (*q.v.*) at the head of

Boat on Frobisher Bay off Baffin Island  
Shostal

the bay is the headquarters of Baffin region, Northwest Territories.

**Fröding, Gustaf** (b. Aug. 22, 1860, Alster, Värmland, Swed.—d. Feb. 8, 1911, Stockholm), lyrical poet who, by uniting colloquial language with a rich musical form, liberated Swedish verse from traditional patterns.

Fröding studied at the University of Uppsala in 1880–83, and again in 1885, but did not take a degree. He worked for 10 years as a journalist at Karlstad, Värmland, though he spent long periods in sanatoriums for treatment of nervous disorders. Stimulated by the revolt against naturalism at the end of the 1880s, in 1891 he published his first collection of poems, *Guitar och dragharmonika (Guitar and Concertina)*. It was followed by *Nya dikter* (1894; "New Poems") and *Stänk och sliker* (1896; "Splashes and Rags"). These three volumes contain the essential Fröding. Passages in the last led to his prosecution for pornography, and, although he was acquitted, the experience was disastrous to a man so scrupulous and sensitive. He managed to publish two more small books of poems, *Nytt och Gammalt* (1897; "New and Old Pieces") and *Gralstänk* (1898; "Grail Splashes"), before his final breakdown. From 1898 to 1905 he was a patient in a mental hospital at Uppsala, and, although he recovered a measure of sanity, he never recovered his health. A collection of

Fröding, 1896  
By courtesy of Albert Bonniers Forlag, Stockholm

verse and prose, *Efterskörd*, was published in 1910, and a posthumous collection, *Reconvalescentia*, appeared in 1913. Fröding also wrote humorous dialect sketches and literary essays.

Fröding's poetic style showed a virtuosity new to Swedish literature and an unusual technical perfection. He was a master of humorous verse, and his drolleries are as effective as the bitter pathos or evocative magic of his serious poetry. Readers were first attracted by the poems inspired by the scenes, characters, and folklore of his native Värmland; but even in his early work there was also a strong personal note of melancholy and revolt and a pathetic quest for a philosophy capable of resolving life's discords.

**Froebel, Friedrich (Wilhelm August)**, Froebel also spelled FRÖBEL (b. April 21, 1782, Oberweissbach, Thuringia, Ernestine Saxony [now in Germany]—d. June 21, 1852, Marienthal, near Bad Liebenstein, Thuringia),

Froebel, detail of a drawing by Friedrich Unger; in the State Museum, Heidecksburg  
By courtesy of the Staatliche Museen, Heidecksburg

German educator who was founder of the kindergarten and one of the most influential educational reformers of the 19th century.

Froebel was the fifth child in a clergyman's family. His mother died when he was only nine months old, and he was neglected as a child until an uncle gave him a home and sent him to school. Froebel acquired a thorough knowledge of plants and natural phenomena while at the same time beginning the study of mathematics and languages. After apprenticeship to a forester, he pursued some informal university courses at Jena until he was jailed for an unpaid debt. He tried various kinds of employment until he impulsively took a teaching appointment at a progressive model school in Frankfurt run by Anton Gruner on lines advocated by the Swiss educator Johann Heinrich Pestalozzi. Froebel became convinced of his vocation as a teacher at the school.

After two years as assistant to Gruner, Froebel went to Yverdon, Switz., where he came into close contact with Pestalozzi. Though he learned much at Yverdon, he quickly discovered the weakness of organization that characterized Pestalozzi's work. In 1811 Froebel entered the University of Göttingen, where military service in the Napoleonic Wars soon interrupted his studies. During the campaign of 1813 he formed a lasting friendship with H. Langenthal and W. Middendorff, who became his devoted followers and who joined him at a school he opened at Griesheim in Thuringia in 1816. Two years later the school moved to Keilhau, also in Thuringia, and it was there that Froebel put into practice his educational theories. He and his friends and their wives became a kind of educational community, and the school expanded into a flourishing institution. During this time Froebel wrote numerous articles and in 1826 published his most important treatise, *Menschenziehung* (*The Education of Man*), a philosophical presentation of principles and methods pursued at Keilhau.

In 1831 Froebel left Keilhau to his partner and accepted the Swiss government's invitation to train elementary school teachers. His experiences at Keilhau and as head of a new orphan asylum at Burgdorf in Switzerland impressed him with the importance of the early stages of education. On returning to Keilhau in 1837 he opened an infant school in Blankenburg, Prussia, that he originally called the Child Nurture and Activity Institute, and

which by happy inspiration he later renamed the Kindergarten, or "garden of children." He also started a publishing firm for play and other educational materials, including a collection of *Mother-Play and Nursery Songs*, with lengthy explanations of their meaning and use. This immensely popular book was translated into many foreign languages. Froebel insisted that improvement of infant education was a vital preliminary to comprehensive educational and social reform. His experiments at the Kindergarten attracted widespread interest, and other kindergartens were started. Unfortunately, because of a confusion with the socialist views of Froebel's nephew, the Prussian government proscribed the kindergarten movement in 1851. The ban was not removed until after 1860, several years after Froebel's death in 1852.

One of Froebel's most enthusiastic disciples, the Baroness of Marenholtz-Bülow, was largely responsible for bringing his ideas to the notice of educators in England, France, and The Netherlands. Later they were introduced into other countries, including the United States, where the Froebelian movement achieved its greatest success. There John Dewey adopted Froebel's principles in his experimental school at the University of Chicago. Kindergartens were established throughout Europe and North America and became a standard educational institution for children of four to six years of age.

Froebel was influenced by the outstanding German idealist philosophers of his time and by Jean-Jacques Rousseau and Pestalozzi. He was a sincerely religious man who, because of his belief in the underlying unity of all things, tended toward pantheism and has been called a nature mystic. His most important contribution to educational theory was his belief in "self-activity" and play as essential factors in child education. The teacher's role was not to drill or indoctrinate the children but rather to encourage their self-expression through play, both individually and in group activities. Froebel devised circles, spheres, and other toys to stimulate learning through well-directed play activities accompanied by songs and music. Modern educational techniques in kindergarten and preschool are much indebted to him. (S.J.C./Ed.)

**BIBLIOGRAPHY.** Irene M. Lilley, *Friedrich Froebel: A Selection from His Writings* (1967), emphasizes aspects of Froebel's life often neglected in other studies. William H. Kilpatrick, *Froebel's Kindergarten Principles Critically Examined* (1916), is a penetrating analysis.

**frog**, any of various tailless amphibians belonging to the order Anura. Used strictly, the term may be limited to any member of the family Ranidae (true frogs), but more broadly the name frog is often used to distinguish smooth-skinned, leaping anurans from squat, warty, hopping ones, which are called toads.

A brief treatment of frogs follows. For full treatment, see MACROPAEDIA: Amphibians.

In general, frogs have protruding eyes, no

Costa Rican flying tree frog (*Agalychnis spurrelli*)  
Heather Angel

tail, strong, webbed hind feet that are adapted for leaping and swimming, and smooth, moist skins. Many are predominantly aquatic, but some live on land, in burrows, or in trees. A number depart from the typical form. Sedge frogs (*Hyperolius*), for example, are climbing African frogs with adhesive toe disks. The dagger frog (*Babina holsti*) of Okinawa has thumbs developed into sharp, daggerlike spines. The flying frogs (*Rhacophorus*) are tree-dwelling, Oriental ranids; they can glide 12 to 15 m (40 to 50 feet) by means of expanded webbing between the fingers and toes.

Frogs range in snout-vent length from 9.8 mm (0.4 inch) in the Brazilian *Psyllophryne didactyla* to 30 cm (12 inches) in the West African *Conraua goliath*. The male anuran is generally smaller than the female.

Although frogs have poisonous skin glands, these toxins do not usually provide protection from predatory mammals, birds, and snakes. Edible anurans rely on camouflage; some blend with their backgrounds, while others change colours. Several species have bright colours on their underparts that flash when the frog moves, possibly confusing enemies. Most frogs eat insects, other small arthropods, or worms, but a number of them also eat other frogs, rodents, and reptiles.

The annual breeding of frogs usually takes place in freshwater. In the sexual embrace (amplexus) the male clasps the female from behind and extrudes sperm over the eggs as they are ejected by the female. The eggs, laid in numbers varying from a few hundred to several thousand (depending on the species), then float off in clusters or sheets and may become attached to the stems of water plants; the eggs of some species sink. The tadpole hatches in a few days to a week or more and metamorphoses into a frog within two months to three years. During metamorphosis the lungs develop, limbs appear, the tail is absorbed, and the mouth becomes typically froglike. In some Oriental species the eggs are deposited on land and the young hatch as froglets, not tadpoles.

**frog orchid** (*Coeloglossum viride*), one of two small terrestrial plants in the genus *Coeloglossum* (family Orchidaceae), native to

Frog orchid (*Coeloglossum viride*)

A. J. Huxley

open places in Great Britain, northern Eurasia, and northern North America. The flowers usually are green or brownish green, occasionally tinged with red, and occur in spikes 5 to 30 cm (2 to 12 inches) tall. The frog orchid bears three to five dark green leaves. There are two tubers below ground that fork into several parts and become threadlike roots.

**frogfish**, any of about 60 species of small marine fishes of the family Antennariidae (or-

der Lophiiformes), usually found in shallow, tropical waters. Frogfishes are robust, rather lumpy fishes with large mouths and, often, prickly skins. The largest species grow about 30 cm (12 inches) long.

Frogfishes, members of the group known as anglerfishes, are usually provided with a "fishing pole," tipped with a fleshy "bait," located on the snout and derived from the first dorsal fin spine. This lure is used to entice prey fish. Frogfishes vary in colour; often patterned to blend with their surroundings, some are able to change colour. They generally lie quietly on the bottom or crawl slowly about with

Sargassum fish (*Histrio histrio*)

Robert Hermes—The National Audubon Society Collection/Photo Researchers—EB Inc

their limblike pectoral fins. The sargassum fish (*Histrio histrio*) is patterned very much like the sargassum weed in which it lives.

**frog hopper**, also called SPITTLERBUG, or CUCKOO SPIT INSECT, any of the approximately 2,000 species of small (rarely more than 1.5 cm [0.6 inch]) hopping insects of the family Cercopidae (order Homoptera). The whitish nymph secretes a fluid through the anus that is mixed with a secretion from the abdominal glands. Air bubbles are introduced through a special valve on the abdomen to create spittle, a frothy substance that protects the larva from enemies and desiccation.

Spittlebug nymph in spittle mass

Alexander B. Klots

The meadow spittlebug (*Philaenus leucophthalmus*), froglike in appearance, has grayish-brown wings and is a powerful leaper; it is found in Europe and North America. Some African species occur in enormous numbers and secrete large amounts of spittle, which drips from tree branches like rain. The sugarcane frog hopper (*Tomasia saccharina*) is very destructive in Trinidad. *Aphrophora* species are serious pests of the willow and pine. One group of frog hoppers secretes small calcareous tubes that resemble snail shells and were once classified as snails by zoologists.

**frogman**, member of a naval underwater demolition team. In World War II their efforts reduced troop losses and facilitated the landing of men and supplies on enemy shores. Before an amphibious landing was made, frogmen reconnoitered the beach area. They measured the actual depths of the water, detected natural or man-made obstructions under the surface, and observed the enemy's defensive positions close to the water's edge. One of their most

important functions was to destroy dangerous underwater obstructions. Frogmen were carefully chosen volunteers who were intensively

Navy frogmen entering the water to inspect the hull of a Polaris submarine

trained and worked without weapons. After the war they performed research and rescue operations.

**frogmouth**, any of numerous birds comprising the family Podargidae, in the order Caprimulgiformes, named for their characteristic broad, froglike gape. Frogmouths inhabit the forests of southeastern Asia and Australia. Unlike the weak bill of the nightjars, that of the frogmouths is substantial and slightly hooked. Their food consists of large insects, small lizards, and mice, taken at night; some frogmouths in Australia also eat berries and fruit. They sleep in a crouching position, lengthwise along a branch, during the day. Frogmouths are protectively coloured, reddish brown or grayish, and range in length from about 25 to 55 cm (10 to 22 inches). There are 12 species in two genera.

The large frogmouth (*Batrachostomus auritus*), a 40-centimetre (16-inch) species of the Malay Peninsula and the islands of Sumatra and Borneo, lays a single egg on a pad of down covered with lichens and spiderweb.

The tawny frogmouth (*Podargus strigoides*), of the Australian mainland and Tasmania, sometimes called "morepork," or "mopoke," because of its call, is about 50 cm (20 inches) long. It lays two or three eggs on a flimsy nest of twigs in the crotch of a tree. Other species occur in the Philippines, New Guinea, and the Solomon Islands.

**Fröhlich's syndrome**, also called ADIPOSEGENITAL DYSTROPHY, rare childhood metabolic disorder characterized by obesity, growth retardation, and retarded development of the genital organs. It is usually associated with tumours of the hypothalamus, causing increased appetite and depressed secretion of gonadotropin. The disease is named for Alfred Fröhlich, the Austrian neurologist who first described its typical pattern.

The syndrome occurs most frequently in boys and, because of the close association between the pituitary and the hypothalamus, may be associated with reduced pituitary function. Impaired vision sometimes results from impingement of the tumour on the optic nerve. Fröhlich's syndrome is treated by removing the tumour and restricting diet until normal weight is achieved.

Many overweight children may appear to have the disorder because of the concurrence of obesity and retarded sexual development; these children have no endocrine disturbances, however, and they mature normally after delayed puberty.

**Frohman, Charles** (b. June 17, 1860, Sandusky, Ohio, U.S.—d. May 7, 1915, at sea), leading American theatrical manager of his time.

Frohman became interested in theatrical activities through his older brothers, Daniel and Gustave. After several years of part-time po-

sitions with local newspapers and theatres, Frohman, in 1883, managed the Wallack Theatre Company on tour. He later opened a theatrical booking office in New York and laid the foundation of the Theatrical Syndicate, which for several years controlled U.S. theatres. Frohman's initial success was Bronson Howard's *Shenandoah* in 1889. In 1892 he engaged John Drew as his star and established the Empire Stock Company. Frohman's encouragement of such playwrights as Clyde Fitch, David Belasco, and Augustus Thomas and stars such as Maude Adams, Ethel Barrymore, Julia Marlowe, Billie Burke, William Gillette, and Otis Skinner was indicative of his ability to perceive theatrical talent. He dominated the American theatre during 25 of its most expansive years, and when he drowned in the sinking of the *Lusitania*, an era ended.

**Frohschammer, Jakob** (b. Jan. 6, 1821, Illkofen, Bavaria [Germany]—d. June 14, 1893, Bad Kreuth), Roman Catholic priest, prolific writer, and philosopher who was excommunicated for claiming that philosophy and church authority are autonomous.

Ordained in 1847, Frohschammer lectured in philosophy from 1850 at the University of Munich (professor from 1855), where he began publishing his first important and controversial works, *Über den Ursprung der menschlichen Seelen. Rechtfertigung des Generationismus* (1854; "On the Origin of Human Souls: Justification for Generationism") and *Menschseele und Physiologie* (1855; "Human Souls and Physiology"). They were placed on the church's *Index of Forbidden Books* in 1857 because of their expressed views on generationism, a condemned theory stating that the human soul is created from unliving matter in the act of procreation. Though Frohschammer's generationist views were moderate, he was early suspected by the church.

On refusing to retract, he was suspended from Munich in 1862, the year he founded *Athenäum*, a periodical of liberal Catholicism for which he wrote the first adequate account in German of Darwin's theory on the origin of species by means of natural selection. Excommunicated in 1871, he replied with *Der Fels Petri in Rom* (1873; "The Rock of Peter in Rome"), *Der Primat Petri und des Papstes* (1875; "The Primacy of Peter and the Popes"), and *Das Christentum Christi und das Christentum des Papstes* (1876; "The Christianity of Christ and the Christianity of the Popes"). His principal later work is considered to be *Die Phantasie als Grundprinzip des Weltprozesses* (1877; "Fantasy as the Basic Principle of Earthly Activities"). Frohschammer's *Philosophie des Thomas von Aquino kritisch gewürdigt* (1889) criticizes St. Thomas Aquinas' view that philosophy is the handmaid of theology. J.G. Wüchner's *Frohschammer's Stellung zum Theismus* ("Frohschammer's Attitude Toward Theism") appeared in 1913.

**Froissart, Jean** (b. 1333?, Valenciennes, Brabant—d. 1400/01, Chimay, Hainaut), European medieval poet and court historian whose *Chronicles* of the 14th century remain the

Froissart (seated) writing his *Chroniques*, miniature from a mid-15th-century manuscript, in the Bibliothèque de l' Arsenal, Paris (Ms. 5190)

By courtesy of the Bibliothèque de l' Arsenal, Paris, photograph, Studio STA Photo

most important and detailed documents of feudal times and the best contemporary exposition of chivalric and courtly ideals.

As a scholar, Froissart lived among the nobility of several European courts. In England he served Queen Philippa of Hainaut, King Edward III, and his sons the Black Prince and the Duke of Clarence; he became the chaplain of Guy II de Chatillon, comte de Blois, under whose auspices he was ordained canon of Chimay. He travelled to Scotland, Italy, France, and the Iberian Peninsula.

The main subject of Froissart's *Chronicles* (Eng. trans. by Lord Berners [1523–25], ed. by W.P. Ker, 6 vol., [1901–03]) was the "honourable adventures and feats of arms" of the Hundred Years' War. He used his privileged position to question central figures and observe key events. The firsthand narrative covers weddings, funerals, and great battles from 1325 to 1400. Book I was based on the work of the Flemish writer Jean le Bel and later rewritten; Book II concerns the events in Flanders and the Peace of Tournai; Book III, Spain and Portugal; and Book IV is based on the Battle of Poitiers and a final visit to England, where he was shocked by the weakness of the royal government.

Froissart cites exact dialogues and all available facts, allowing the reader to draw his own conclusions. The splendour and pageantry are emphasized, however, according to the courtly traditions of his patrons, while the victims and causes of suffering are overlooked. A didactic moral tone urges readers to aspire to the ideals of chivalry.

Froissart's allegorical poetry celebrates courtly love. *L'Horloge amoureux* compares the heart to a clock, and *Méliador* is a chivalrous romance. His ballades and rondeaux expose the poet's personal feelings. Despite his fame during his lifetime, Froissart apparently died in obscurity; his tomb has never been discovered.

**Frome, Lake**, in northeastern South Australia, large, shallow depression 60 mi (100 km) long by 30 mi wide, intermittently filled with water, 280 mi northeast of Adelaide. It is the southernmost of an arc of such salt lakes northeast of the Flinders Range, including Lakes Gregory, Blanche, and Callabonna, all sharing a common origin in a larger ancestral Lake Eyre (to the northwest). Unless it receives water from fluctuating heavy rains in the northern Flinders or an overflow from

Lake Callabonna, Frome is a dry salt pan (playa). Sighted in 1840 by Edward J. Eyre, who was seeking new grazing lands, it was considered an extension of Lake Torrens (80 mi west) until 1858. It is named after E.C. Frome, surveyor general of South Australia in the 1840s.

**Froment, Nicolas** (b. Uzès, Fr.; fl. 1450–90 in the south of France), French painter who shared the responsibility (with Enguerrand Charonton) for introducing Flemish naturalism into French art.

During the 15th century, Italian art was so admired in France that the works of French artists were ignored or disdained. In response, Froment and Charonton around 1450 set up their own school in Avignon, where they formed the core of the realists of the school of primitive artists of Provence. Although many of their works were in demand at the time, they were neglected afterward.

Froment stands out among his colleagues for his rather crude and unpolished style, marked by awkward design and lack of sensitivity to colour. Nonetheless, many appreciated his revolutionary art, which introduced the often macabre Flemish style into French painting, as can be seen in his "Resurrection of Lazarus" (1461; Uffizi, Florence). The "Burning Bush" (1475–76), which illustrates his application of the Flemish style to the legends and landscape of Provence, is perhaps Froment's most illus-

Central panel of the triptych of the "Burning Bush" by Nicolas Froment, 1475–76; in the Cathédrale de Saint-Sauveur, Aix-en-Provence, Fr.

trious work. The painting was done for King René of Anjou and depicts the King and his wife with several saints.

**Fromentin, Eugène** (b. Oct. 24, 1820, La Rochelle, Fr.—d. Aug. 27, 1876, La Rochelle), French painter and author, best known for his depictions of the land and people of Algeria.

Influenced successively by Jean-Baptiste-Camille Corot and Eugène Delacroix, Fromentin abandoned his early stiffness in design and execution and developed into a brilliant colourist. "Fauconnier arabe" and "Chasse au héron" clearly show his debt to Delacroix.

Fromentin's paintings show only one side of a talent that was perhaps even more felicitously expressed in literature; "Dominique," first published in the *Revue des Deux Mondes* in 1862 and dedicated to George Sand, is remarkable among the fiction of the century for imaginative observation. Fromentin's other literary works are *Visites artistiques ou*

*Simplex Pélerinages* (1852–56); *Un Été dans le Sahara* (1857); *Une Année dans le Sahel* (1858); and *Les Maîtres d'autrefois* (1876).

**Fromm, Erich** (b. March 23, 1900, Frankfurt am Main—d. March 18, 1980, Muralto, Switz.), German-born U.S. psychoanalyst and social philosopher who explored the interaction between psychology and society. By apply-

Fromm

By courtesy of Michigan State University

ing psychoanalytic principles to the remedy of cultural ills, Fromm believed, mankind could develop a psychologically balanced "sane society."

After receiving his Ph.D. from the University of Heidelberg in 1922, Fromm trained in psychoanalysis at the University of Munich and at the Psycho-Analytic Institute of Berlin. He began practicing psychoanalysis as a disciple of Sigmund Freud but soon took issue with Freud's preoccupation with unconscious drives and consequent neglect of the role of societal factors in human psychology. For Fromm, an individual's personality was the product of his culture as well as his biology. He had already attained a distinguished reputation as a psychoanalyst when he left Nazi Germany in 1933 for the United States. There he came into conflict with orthodox Freudian psychoanalytic circles. From 1934 to 1941 Fromm was on the faculty of Columbia University, where his views became increasingly controversial. In 1941 he was a member of the faculty at Bennington College in Vermont, and in 1951 he was appointed professor of psychoanalysis at the Universidad Nacional Autónoma de México (National Autonomous University of Mexico), Mexico City. From 1957 to 1961 he concurrently held a professorship at Michigan State University, East Lansing, finally returning to New York City in 1962 as professor of psychiatry at New York University.

In several books and essays, beginning with an essay (1930) on the development of Christian doctrine and symbolism (translated into English as *The Dogma of Christ and Other Essays on Religion, Psychology, and Culture*, 1963), Fromm presented the view that an understanding of basic human needs is essential to the understanding of society and mankind itself. Fromm argued that social systems make it difficult or impossible to satisfy the different needs at one time, thus creating both individual psychological and wider, societal conflicts. In Fromm's first major work, *Escape from Freedom* (1941), he charted the growth of human freedom and self-awareness from the Middle Ages to modern times and, using psychoanalytic techniques, analyzed the tendency of modern emancipated man to take refuge from his new insecurities by turning to totalitarian movements such as Nazism.

In *The Sane Society* (1955), Fromm presented his argument that modern man has become alienated and estranged from himself

within consumer-oriented industrial society. Fromm called for a rebirth of enlightenment in a new and perfect society which would allow each person to fulfill his individual needs while maintaining his sense of belonging through bonds of social brotherhood.

Fromm's voluminous writings on human nature, ethics, and love attracted the interest of social scientists and a wide general readership. He also wrote books of criticism and analysis on Freudian and Marxist thought, psychoanalysis, and religion. Others of his books included *Man for Himself* (1947), *Psychoanalysis and Religion* (1950), *The Art of Loving* (1956), *May Man Prevail?* (1961, with D.T. Suzuki and R. De Martino), *Beyond the Chains of Illusion* (1962), *The Revolution of Hope* (1968), and *The Crisis of Psychoanalysis* (1970).

**Fronde, the,** French LA FRONDE, series of civil wars in France between 1648 and 1653, during the minority of Louis XIV. The Fronde (the name for the "sling" of a children's game played in the streets of Paris in defiance of civil authorities) was in part an attempt to check the growing power of royal government; its failure prepared the way for the absolutism of Louis XIV's personal reign.

The Fronde was a reaction to the policies begun under the Cardinal de Richelieu, chief minister of Louis XIII from 1624 to 1642, who weakened the influence of the nobility and reduced the powers of the judicial bodies, called Parlements. Opposition to the government from these privileged groups gained momentum from 1643 under the "foreign" rule of the queen regent Anne of Austria (Louis XIV's mother) and her Italian-born chief minister, Jules Cardinal Mazarin.

The refusal of the Parlement of Paris to approve the government's revenue measures in the spring of 1648 set off the first phase, the Fronde of the Parlement. The Parlement sought to put a constitutional limit on the monarchy by establishing its power to discuss and modify royal decrees. From June 30 to July 12 an assembly of courts made a list of 27 articles for reform, including abolition of the intendants (officials of the central government in the provinces), tax reductions, approval of all new taxes by the Parlement, and an end to arbitrary imprisonment. On July 31, Mazarin's government—at war with Spain—reluctantly agreed to many of the demands. With news of a victory over the Spanish, however, Anne and Mazarin felt strong enough to arrest two outspoken *parlementaires* on August 26, but an uprising in Paris forced the queen and her minister to release them two days later.

The conflict broke into war in January 1649. A blockade of Paris was not enough to force the surrender of the Parlement, which was supported by Parisian leaders and by some of the high nobility. Faced with disturbances in the provinces and the continuing foreign war, the government negotiated the Peace of Rueil (ratified April 1, 1649), which granted amnesty to the rebels and confirmed the concessions to Parlement.

The Fronde of the Princes, the second phase of the civil war (January 1650 to September 1653), was a complex of intrigues, rivalries, and shifts of allegiance in which constitutional issues gave way to personal ambitions. One common factor among the aristocratic rebels was opposition to Mazarin, who, throughout the Fronde, was the target of fierce attacks by pamphleteers. The Great Condé, a great military leader and cousin of the king, had helped the government in the war against the Parlement. Disappointed in his hope for political power, he became rebellious. When he was arrested, on Jan. 18, 1650, his friends took up arms in a series of uprisings in the provinces, called the first war of the princes. By the end of 1650 the government had dealt

successfully with the revolts. In reaction, the supporters of Condé and the Parisian party (sometimes called the Old Fronde) united to bring about the release of Condé and the dismissal of Mazarin (February 1651). Condé was dominant for a brief period.

Anne, however, knew how to exploit the divisions among the Frondeurs. She joined with the Old Fronde and ordered an indictment of Condé in August 1651, an act that decided Condé on war—the second war of the princes (September 1651 to September 1653). A main event of the war was Condé's entrance into Paris in April 1652. Despite Spanish aid, his position soon weakened: he was almost defeated by royal troops outside the walls of Paris (July 2, 1652), lost the support of the Parisian bourgeoisie, and never gained the approval of the Parlement. In the face of opposition, Condé left Paris on October 13 and eventually fled to the Spanish Netherlands. The king entered Paris in triumph on Oct. 21, 1652, followed by Mazarin on Feb. 3, 1653. With many of the nobles in exile and with the Parlement forbidden to interfere in royal administration, the Fronde ended in a clear victory for Mazarin.

Beyond the immediate victory, the Fronde had an impact on French history of the last half of the 17th century: by revealing the selfish interests of the nobility and the Parlement and their inability to offer effective leadership, the Fronde lost for these groups a role as a counterbalance to the king. The Fronde was the last serious challenge to the supremacy of the monarchy in France until the Revolution of 1789.

first

**front,** in meteorology, interface or transition zone between two air masses of different density and temperature; the sporadic flareups of weather along this zone, with occasional thunderstorms and electrical activity, was, to the Norwegian meteorologists who gave it its name during World War I, analogous to the fighting along the battle line in Europe. Frontal zones are frequently accompanied by low barometric pressure (a pressure trough), marked changes in wind direction and relative humidity, and considerable cloudiness and precipitation.

There are several different types of front, depending basically on which air mass is displacing the other at the ground. Meteorologists call the leading edge of an advancing mass of relatively cold air a cold front. In middle latitudes of both hemispheres, cold fronts tend to move toward the Equator and eastward, with the most advanced position right at the ground. At a height of about 1.5 km (1 mile), the front usually lies 80 to 160 km (50 to 100 miles) behind its surface position; thus, its slope is  $1/50$  to  $1/100$ . A cold front is usually associated with showers and thunderstorms. As it advances, often quite rapidly (50 to 65 km [30 to 40 miles] per hour), the cold air, which is relatively dense, undercuts the displaced warm air, forcing it to rise. In extreme cases, the resulting instability may lead to the formation of a squall line of severe thunderstorms and possibly tornadoes parallel to and about 80 km ahead of the surface position of the cold front. The precipitation usually stops abruptly after the front passes.

A warm front is the boundary between an advancing mass of warm air and a retreating mass of cold air. At constant atmospheric pressure, warm air is less dense than cold air, and so it tends to override, rather than displace, the cold air. As a result, a warm front usually moves quite slowly, if at all. Warm fronts are often quite diffuse and difficult to

locate precisely. Their inclination, or slope, is much less than that of cold fronts. At a height of about 1.5 km, the front usually lies about 320 km (200 miles) ahead (to the north or northeast in the Northern Hemisphere) of its surface position. Warm-front precipitation is generally much more uniform and widespread than that associated with cold fronts. Sometimes in winter, if the warm air overrides cold air at subfreezing temperatures, severe ice storms may develop more than 100 km (62 miles) ahead of the surface position of the warm front.

If, as often happens, a warm front is quickly overtaken by a cold front moving rapidly around a low-pressure centre, the end result is an occluded front, characterized by low temperatures, much cloudiness, and widespread precipitation, often in the form of snow. Cyclonic storms in middle latitudes often start out as an undulation, or wave, on a preexisting frontal boundary between warm and cold air masses. As the wave moves and intensifies, its amplitude increases in much the same way that the amplitude of an ocean wave, starting out as a ripple, increases as it moves shoreward. Eventually, the advancing cold air behind the cold front catches up with the slower-moving cold air under the warm front. The intervening tongue of warm air is pushed aloft, and the wave breaks or becomes occluded. At this point the kinetic energy of the storm, derived from the sinking of cold air and the rising of warm air, usually reaches its maximum intensity. A wave cyclone, with its attendant low atmospheric pressure and stormy weather, occasionally develops on a so-called stationary front (a boundary between air masses with different thermal characteristics that has little or no horizontal motion). Storms affecting the northeastern United States, for example, often develop from a perturbation on a stationary front over the southern or southeastern states; such storms are often quite severe, the energy of motion being provided by the large thermal contrast between cold polar air to the north and warm tropical air to the south.

The variable weather conditions that are typical of middle latitudes are associated largely with fluctuations in the location and intensity of a semipermanent, semicontinuous boundary known as a polar front. Polar fronts, located between 30° and 60° latitude in both hemispheres, average about 160 km (100 miles) in width. Very often a jet stream of strong westerly winds—driven by the large thermal contrast between the cold, dry polar air and the warm, moist tropical air—is located 10 to 12 km (6 to 7 miles) directly above the location of the front. The strong thermal contrast within the front serves as a source of potential energy for the development of cyclonic (centred on a low-pressure area) storm systems along the front.

The region near the Equator in which the trade winds of the two hemispheres meet was once designated the equatorial, or intertropical, front. Although the wind and weather patterns of this region closely resemble those found along fronts in middle latitudes (*i.e.*, they exhibit long lines of cumulonimbus clouds, a rapid wind shift, and a sharp drop in temperature), most modern tropical meteorologists prefer the name equatorial-trough disturbance, because the observed cooling that occurs in the disturbed zone is attributed to evaporation of falling rain and the lack of direct sunlight rather than to the replacement of one air mass by another.

**Front Range,** easternmost section of the central and southern Rockies, extending about 300 miles (480 km) south-southeastward from near Casper in southeastern Wyoming, U.S., to Fremont County in south-central Colorado.

It is from 40 to 50 miles (65 to 80 km) wide and includes Laramie and Medicine Bow mountains (*qq.v.*), while the Sangre de Cristo Mountains are usually regarded as an extension. Many summits exceed 13,000 feet (4,000 m), including Mount Evans (14,264 feet [4,348 m]; the range's highest peak) and Pikes Peak (14,110 feet [4,300 m]). Notable passes are Berthoud (11,315 feet [3,449 m]) and Loveland (11,990 feet [3,655 m]).

Lying largely within conservation areas, the Front Range comprises parts of the Rocky Mountain National Park and Pike, Arapaho, Routt, Roosevelt, and Medicine Bow national forests. The range is known for its variety of minerals and recreational appeal, and it serves as a source region for headstreams of the Cache La Poudre and Colorado rivers.

**Frontenac, Louis de Buade, comte de Palluau et de** (count of Palluau and of) (b. May 22, 1622, Saint-Germain-en-Laye, near Paris, Fr.—d. Nov. 28, 1698, Quebec, New France [now in Canada]), French courtier and governor of New France (1672–82, 1689–98), who, despite a record of misgovernment, managed to encourage profitable explorations westward and to repel British and Iroquois attacks on New France.

Frontenac's father, Henri de Buade, was colonel of the Régiment de Navarre and a member of Louis XIII's entourage. The young Frontenac served with the French armies during the Thirty Years' War; by 1643, at the age of 21, he was colonel of the Régiment de Normandie, and in 1646 he was appointed a *maréchal de camp* (brigadier general).

Frontenac had great personal charm and much influence at court, but he was also egoistic and unscrupulous, as well as extravagant; by 1663 his debts amounted to more than 350,000 livres. In 1669 he took service as lieutenant general with the Venetian forces defending Crete against the Turks, but he had not been on the island long before he was dismissed from his post for intriguing against his superior officers.

In 1672 he was appointed governor-general of New France. Within a year of his arrival in the colony, he had founded a fur-trading post, Fort Frontenac, on Lake Ontario. Shortly afterward he became associated with the French explorer René-Robert Cavalier, Sieur de La Salle, who, with Frontenac's support, obtained royal consent to continue the explorations of Louis Jolliet down the Mississippi River to its mouth. La Salle took advantage of this to found fur-trading posts at the foot of Lake Michigan and on the Illinois River, from which his men, with the connivance of Frontenac, illegally engrossed a large part of the western fur trade. This brought them into conflict with the Montreal fur traders, dividing the New France colony into two hostile factions. Despite repeated warnings from Louis XIV and his minister J.-B. Colbert, Frontenac also disputed violently with the officials and clergy of New France.

While these conflicts were raging within the colony, a much more serious external problem was developing. Until 1675 the Five Nations of the Iroquois Indian confederacy had remained on good terms with the French because they were under attack from the Andaste and Mohegan tribes; but in that year the Iroquois subdued the other tribes and immediately began to contest the French hold on the western fur trade, their aim being to divert it from Montreal to Albany, with themselves acting as middlemen. When they attacked the tribes allied to the French and threatened the French themselves, Frontenac tried to appease them, doing nothing to strengthen the colony's almost nonexistent defenses. This policy merely encouraged the Iroquois to press their

attacks with greater vigour, until the French were in danger of being driven out of the west. During these years, too, the English Hudson's Bay Company established posts in James Bay, posing another threat to the Canadian fur trade, one that Frontenac chose to ignore. In 1682 Louis XIV recalled Frontenac because of his misgovernment. (His successors eventually brought the Indians to terms.)

When England declared war on France in May 1689, Frontenac was given command of an expedition to conquer the English province of New York. At the same time, he was reappointed governor of New France. Frontenac's expedition was delayed by adverse weather, however, and he did not reach Quebec until October 12. The Iroquois, meanwhile, learning of Anglo-French hostilities before the news reached New France, had launched a furious assault on the unsuspecting colony on August 5, inflicting great damage and killing or capturing about 100 Canadians. This attack, and the lateness of the season when Frontenac reached the colony, made it impossible to invade New York in force; but in January he sent three war parties to attack the English frontier settlements at Schenectady, Fort Loyal, and Salmon Falls. All three places were destroyed with heavy loss of life for the defenders, and as a result the northern English colonies united for an assault on New France. The attacking forces, led by Sir William Phips, were repulsed at Quebec by the French under Frontenac, who distinguished himself by his prudent tactics.

During the next few years the fighting was confined to sporadic raids on the Canadian settlements by the Iroquois, but this did not prevent a rapid expansion into the west by the Canadian fur traders. Frontenac concerned himself far more with the fur trade than with pressing the war to a successful conclusion. Despite Louis XIV's policy of curbing expansion into the interior in order to strengthen the central colony, old fur-trading posts were strengthened and new posts established by Frontenac until French influence extended beyond Lake Superior, and the flood of furs coming down to Montreal glutted the market in France. After much urging from his subordinates and the receipt of explicit orders from the Minister of the Marine, Frontenac finally undertook in 1696 an expedition that destroyed the villages of two of the Iroquois nations. The following year the war between England and France ended, but it was not until 1701 that a peace treaty was ratified with the Iroquois by Frontenac's successor.

Frontenac was one of the more colourful personages in North American history. His connections at the court of Louis XIV enabled him to survive failures that might have destroyed another man and won him credit for the achievements of his subordinates. It was, however, under his regime that the English and Iroquois attacks on New France were finally repulsed and the French extended their North American empire from Montreal to Lake Winnipeg and from Hudson Bay to the Gulf of Mexico. **BIBLIOGRAPHY.** Francis Parkman, *France and England in North America*, pt. 5, *Count Frontenac and New France Under Louis XIV* (1877, reprinted 1983); W.J. Eccles, *Frontenac: The Courtier Governor* (1959, reissued 1965).

**frontier humour**, vital and exuberant literature that was generated by the westward expansion of the United States in the late 18th and the 19th centuries. The spontaneity, sense of fun, exaggeration, fierce individuality, and irreverence for traditional Eastern values in frontier humour reflect the optimistic spirit of pre-Civil War America. Frontier humour appears mainly in tall tales of exaggerated feats of strength, rough practical jokes (especially on sophisticated Easterners and greenhorns), and tales of encounters with panthers, bears,

and snakes. These tales are filled with rough, homely wisdom.

Davy Crockett, whose *Narrative* (1834) is a combination of tall tales, comic self-portraiture, and humorous proverbs, is the classic proponent of frontier humour. Others include Mike Fink, king of the Mississippi River keelboatmen, and Paul Bunyan, hero of the northwestern loggers. Representative writers of Southern frontier humour are A.B. Longstreet, Thomas B. Thorpe, Johnson Jones Hooper, and George Washington Harris. Mark Twain represents a culmination of the tradition. *See also* local colour.

**Frontinus, Sextus Julius** (b. c. AD 35—d. c. 103), Roman soldier, governor of Britain, and author of the *De aquis urbis Romae* ("Concerning the Waters of the City of Rome"), a history and description of the water supply of Rome, including the laws relating to its use and maintenance and other matters of importance in the history of architecture.

In 70 Frontinus was city praetor in Rome, and about five years later he succeeded Petilius Cerealis as governor of Britain. He subdued the Silures, a tribe in southeast Wales, and held the other tribes in check until he was superseded by Agricola (77). In 97 he was appointed superintendent of the aqueducts (*curator aquarum*) at Rome. Frontinus' *De aquis* provides complete technical details on the aqueducts of Rome, along with their history and the regulations governing their use. His treatise *De re militari* ("On Military Matters") is lost. His *Strategematicon libri iii* is a collection of examples of military stratagems from Greek and Roman history; a fourth book, the plan and style of which is different from the rest (more stress is laid on the moral aspects of war, such as discipline), is the work of another writer known as Pseudo-Frontinus. Extracts from a treatise on land surveying ascribed to Frontinus are preserved in C. Lachmann's *Gromatici veteres* (1848).

**Fronto, Marcus Cornelius** (b. c. AD 100, Cirta, Numidia [now Constantine, Alg.]—d. c. 166, Rome?), prominent Roman orator, rhetorician, and grammarian whose high reputation—equal in ancient times to those of Cato, Cicero, and Quintilian—was based chiefly on his orations, all of which are lost. Fronto was educated at Carthage and in Rome, where, under the emperor Hadrian, he rapidly gained considerable fame as an advocate. Emperor Antoninus Pius appointed him tutor to Marcus Aurelius and Lucius Verus; with the former he remained on terms of affectionate friendship. He became *consul suffectus* in 143.

In addition to his orations, Fronto's grammatical and rhetorical studies won him a number of followers, called the Frontoniani. Modern evaluations of Fronto's mastery of language are based on the information contained in the *Noctes Atticae* of Aulus Gellius, a member of Fronto's circle; on a collection of Fronto's letters (principally to Marcus Aurelius and Lucius Verus); and on miscellaneous pieces discovered in 1815 in the Ambrosian Library in Milan. The letters throw useful light on the Antonines and on Fronto's judgments of earlier writers and his precepts about language and style.

Fronto tried to reinvigorate the decaying Latin of his day by reviving the vocabulary of earlier republican Roman writers. The resulting *elocutio novella* ("new elocution") was often artificial and pedantic, but it had widespread influence and gave new vitality to Latin prose writing.

**Frosinone**, Latin *FRUSINO*, city, capital (since 1926) of Frosinone *provincia*, Lazio (Latium) *regione*, central Italy, on a hill above the Cosa River, on the Via Casilina. It originated as Frusino, a town of the ancient Volsci people, and became a *colonia* (colony) of the Roman

Empire. There are traces of ancient walls and a Roman amphitheatre, but Frosinone, which was badly damaged during World War II, is now a primarily modern town. It is the centre of the Ciociaria district (noted for peasant costumes), and agriculture is the economic mainstay. Pop. (1993 est.) mun., 46,023.

**frost**, atmospheric moisture directly crystallized on the ground and on exposed objects. The term also refers to the occurrence of sub-freezing temperatures that affect plants and crops.

Frost crystals, often called hoarfrost in the aggregate, form when the invisible water vapour of the atmosphere passes into the ice-crystal phase without going through the intermediate liquid phase. Hoarfrost lightly covers fields and rooftops under conditions that would form dew (*q.v.*) if the temperature were above freezing at the point of formation. Sometimes the freezing temperature will be reached after dew has already formed, producing frozen dew, but this usually cannot be readily distinguished because crystals ordinarily will start forming at about the same time the freezing starts.

The crystalline and other forms of frost deposit are a subject of aesthetic as well as scientific interest. The structures differ in some respects from those of snow. Granular forms are called rime and are produced by the freezing of droplets of liquid water (technically called supercooled droplets) that are carried in the air at temperatures below freezing. Rime is best developed on mountaintops enveloped in supercooled clouds. It is a common form of icing on aircraft. It also occurs in steam fogs around open springs, streams, lakes, or ponds in very cold weather and, in extreme conditions, around chimneys from the water vapour condensed in the flue gases.

True crystalline hoarfrost is of two classes, one of which assumes columnar forms and the other of which assumes tabular, or plate-like, forms. Generally the crystals of these two classes do not occur together on a single night; rather, one or the other will greatly predominate. Columnar or needlelike forms are found at the higher subfreezing temperatures, whereas plate crystals predominate under colder conditions. In their pristine state both forms are hexagonal crystals, the columns having a hexagonal cross section and the plates appearing as flat hexagons. Because they must grow outward from some supporting object, they rarely assume the perfect symmetry found in many snow crystals. Over ice-covered ponds and rivers, beautiful clusters or rosettes of fernlike or jewel-like frost collect on the surface of the ice. At very low temperatures, cubical crystals are sometimes found.

In cold weather, striking frost forms are often found on the inner surfaces of windowpanes in buildings. In most cases with heated rooms the vapour condenses as a liquid first, but if the conditions are right, as in an unheated room, the delicate, pure crystalline forms are predominant, evoking a variety of fanciful descriptions.

In gardening and horticulture, frost refers to the freezing of the aqueous solutions in the plant cells, causing these to burst and destroy the plant. Only plants containing plentiful and dilute solutions in their leaves, fruits, and so on, are easily damaged. The occurrence of a killing frost without a hoarfrost deposit is sometimes popularly called a black frost.

The most important aspect of frost in relation to plants is its determination of the length of the growing season: the period from the last killing frost in spring to the first killing frost in autumn, with reference to the tenderest crop plants. There are regions of the Earth where the season reaches critically short duration for the maturing of most usable crops and others where the season is so long that more than one planting of such crops as corn

(maize) and alfalfa can be brought to harvest. In regions where frost is rare or absent, other factors take on more importance.

One of the most critical situations for frost is encountered in the citrus-fruit regions. There the few killing frosts likely each winter are combated by a variety of methods, including heating the groves with special burners using oil or a petroleum-derived solid fuel, mixing the air with large fans mounted above the trees, or casting a fine water spray over and on the trees to keep the temperature at or very near the nondamaging level of 32° F (0° C).

**Frost, A.B.**, in full ARTHUR BURDETT FROST (b. Jan. 17, 1851, Philadelphia, Pa., U.S.—d. June 22, 1928, Pasadena, Calif.), American illustrator, famous for his drawings of Uncle Remus, Brer Rabbit, and other characters created by Joel Chandler Harris, an American writer of Southern dialect folktales.

In his teens Frost learned something of wood engraving and lithography before moving to New York, where he worked for the *Graphic* in 1875. He later contributed illustrations to *Harper's Weekly*, *Scribner's Monthly*, and *Collier's* magazines and illustrated Lewis Car-

roll's *Rhyme? and Reason?* In 1877-78 he worked briefly in London and from 1908 to 1916 in Paris. His work captured the appearance and characteristics of rural and small-town American types. His *Book of Drawings* was published in 1904.

**Frost, John** (b. May 25, 1784, Newport, Monmouthshire, Eng.—d. July 27, 1877, near Bristol, Gloucestershire), hero of Chartism (a British political reform movement of working-class origin) and leader of the Newport rising of Nov. 4, 1839, in which about 20 Chartists were killed by troops.

A prosperous draper and tailor in Newport, Frost served as a member of Newport's first elected town council (from 1835), as magistrate (1836-39), and as mayor (1836-37). He was a delegate from Monmouthshire to the Chartist convention in London (February-September 1839) and occasionally was convention chairman, in which capacity his tie-breaking vote dissolved the assembly. Returning to Newport, he became involved in militant Chartist activities that culminated in the street battle on November 4.

Convicted (Jan. 16, 1840) of high treason, Frost received a death sentence, which was commuted to exile for life to Van Diemen's Land (now Tasmania). Released in 1854 on

John Frost, engraving by W. Read after a painting

By courtesy of the trustees of the British Museum, photograph, J.R. Freeman & Co. Ltd.

condition that he leave British territory, he was granted a full pardon in 1856, whereupon he returned to England and lived in retirement.

**Frost, Robert**, in full ROBERT LEE FROST (b. March 26, 1874, San Francisco, Calif., U.S.—d. Jan. 29, 1963, Boston, Mass.), American poet who was much admired for his depictions of the rural life of New England, his command of American colloquial speech, and his realistic verse portraying ordinary people in everyday situations.

*Life.* Frost's father, William Prescott Frost, Jr., was a journalist with ambitions of establishing a career in California, and in 1873 he and his wife moved to San Francisco. Her husband's untimely death from tuberculosis in 1885 prompted Isabelle Moodie Frost to take her two children, Robert and Jeanie, to Lawrence, Mass., where they were taken in by the children's paternal grandparents. While their mother taught at a variety of schools in New Hampshire and Massachusetts, Robert and Jeanie grew up in Lawrence, and Robert graduated from high school in 1892. A top student in his class, he shared valedictorian honours with Elinor White, with whom he had already fallen in love.

Robert and Elinor shared a deep interest in poetry, but their continued education sent Robert to Dartmouth College and Elinor to St. Lawrence University. Meanwhile, Robert continued to labour on the poetic career he had begun in a small way during high school; he first achieved professional publication in 1894 when *The Independent*, a weekly literary journal, printed his poem "My Butterfly: An Elegy." Impatient with academic routine, Frost left Dartmouth after less than a year. He and Elinor married in 1895 but found life difficult, and the young poet supported them

Robert Frost, 1954

Ruohomas—Black Star

by teaching school and farming, neither with notable success. During the next dozen years, six children were born, two of whom died early, leaving a family of one son and three daughters. Frost resumed his college education at Harvard University in 1897 but left after two years' study there. From 1900 to 1909 the family raised poultry on a farm near Derry, N.H., and for a time Frost also taught at the Pinkerton Academy in Derry. Frost became an enthusiastic botanist and acquired his poetic persona of a New England rural sage during the years he and his family spent at Derry. All this while he was writing poems, but publishing outlets showed little interest in them.

By 1911 he was fighting against discouragement. Poetry had always been considered a young person's game, but Frost, who was nearly 40 years old, had not published a single book of poems and had seen just a handful appear in magazines. In 1911 ownership of the Derry farm passed to Frost. A momentous decision was made: to sell the farm and use the proceeds to make a radical new start in London, where publishers were perceived to be more receptive to new talent. Accordingly, in August 1912 the Frost family sailed across the Atlantic to England. Frost carried with him sheaves of verses he had written but not gotten into print. English publishers in London did indeed prove more receptive to innovative verse, and, through his own vigorous efforts and those of the expatriate American poet Ezra Pound, Frost within a year had published *A Boy's Will* (1913). From this first book, such poems as "Storm Fear," "Mowing," and "The Tuft of Flowers" have remained standard anthology pieces.

*A Boy's Will* was followed in 1914 by a second collection, *North of Boston*, that introduced some of the most popular poems in all of Frost's work, among them "Mending Wall," "The Death of the Hired Man," "Home Burial," and "After Apple-Picking." In London, Frost's name was frequently mentioned by those who followed the course of modern literature, and soon American visitors were returning home with news of this unknown poet who was causing a sensation abroad. The Boston poet Amy Lowell traveled to England in 1914, and in the bookstores there she encountered Frost's work. Taking his books home to America, Lowell then began a campaign to locate an American publisher for them, meanwhile writing her own laudatory review of *North of Boston*.

Without his being fully aware of it, Frost was on his way to fame. The outbreak of World War I brought the Frosts back to the United States in 1915. By then Amy Lowell's review had already appeared in *The New Republic*, and writers and publishers throughout the Northeast were aware that a writer of unusual abilities stood in their midst. The American publishing house of Henry Holt had brought out its edition of *North of Boston* in 1914. It became a best-seller, and, by the time the Frost family landed in Boston, Holt was adding the American edition of *A Boy's Will*. Frost soon found himself besieged by magazines seeking to publish his poems. Never before had an American poet achieved such rapid fame after such a disheartening delay. From this moment his career rose on an ascending curve.

Frost bought a small farm at Franconia, N.H., in 1915, but his income from both poetry and farming proved inadequate to support his family, and so he lectured and taught part-time at Amherst College and at the University of Michigan from 1916 to 1938. Any remaining doubt about his poetic abilities was dispelled by the collection *Mountain Interval* (1916), which continued the high level established by his first books. His reputation was

further enhanced by *New Hampshire* (1923), which received the Pulitzer Prize. That prize was also awarded to Frost's *Collected Poems* (1930) and to the collections *A Further Range* (1936) and *A Witness Tree* (1942). His other poetry volumes include *West-Running Brook* (1928), *Steeple Bush* (1947), and *In the Clearing* (1962). Frost served as a poet-in-residence at Harvard (1939-43), Dartmouth (1943-49), and Amherst College (1949-63), and in his old age he gathered honours and awards from every quarter. His recital of his poem "The Gift Outright" at the inauguration of President John F. Kennedy in 1961 was a memorable occasion.

*Works.* The poems in Frost's early books, especially *North of Boston*, differ radically from late 19th-century Romantic verse with its ever-benign view of nature, its didactic emphasis, and its slavish conformity to established verse forms and themes. Amy Lowell called *North of Boston* a "sad" book, referring to its portraits of inbred, isolated, and psychologically troubled rural New Englanders. These off-mainstream portraits signaled Frost's departure from the old tradition and his own fresh interest in delineating New England characters and their formative background. Among these psychological investigations are the alienated life of Silas in "The Death of the Hired Man," the inability of Amy in "Home Burial" to walk the difficult path from grief back to normality, the rigid mindset of the neighbour in "Mending Wall," and the paralyzing fear that twists the personality of Doctor Magoon in "A Hundred Collars."

The natural world, for Frost, wore two faces. Early on he overturned the Emersonian concept of nature as healer and mentor in a poem in *A Boy's Will* entitled "Storm Fear," a grim picture of a blizzard as a raging beast that dares the inhabitants of an isolated house to come outside and be killed. In such later poems as "The Hill Wife" and "Stopping by Woods on a Snowy Evening," the benign surface of nature cloaks potential dangers, and death itself lurks behind dark, mysterious trees. Nature's frolicsome aspect predominates in other poems such as "Birches," where a destructive ice storm is recalled as a thing of memorable beauty. Although Frost is known to many as essentially a "happy" poet, the tragic elements in life continued to mark his poems, from "Out, Out—" (1916), in which a lad's hand is severed and life ended, to a fine verse entitled "The Fear of Man" from *Steeple Bush*, in which human release from pervading fear is contained in the image of a breathless dash through the nighttime city from the security of one faint street lamp to another just as faint. Even in his final volume, *In the Clearing*, so filled with the stubborn courage of old age, Frost portrays human security as a rather tiny and quite vulnerable opening in a thickly grown forest, a pinpoint of light against which the encroaching trees cast their very real threat of darkness.

Frost demonstrated an enviable versatility of theme, but he most commonly investigated human contacts with the natural world in small encounters that serve as metaphors for larger aspects of the human condition. He often portrayed the human ability to turn even the slightest incident or natural detail to emotional profit, seen at its most economical form in "Dust of Snow":

The way a crow  
Shook down on me  
The dust of snow  
From a hemlock tree

Has given my heart  
A change of mood  
And saved some part  
Of a day I had rued.

Other poems are portraits of the introspective mind possessed by its own private demons, as

in "Desert Places," which could serve to illustrate Frost's celebrated definition of poetry as a "momentary stay against confusion":

They cannot scare me with their empty spaces  
Between stars—on stars where no human race  
is.

I have it in me so much nearer home  
To scare myself with my own desert places.

Frost was widely admired for his mastery of metrical form, which he often set against the natural rhythms of everyday, unadorned speech. In this way the traditional stanza and metrical line achieved new vigour in his hands. Frost's command of traditional metrics is evident in the tight, older, prescribed patterns of such sonnets as "Design" and "The Silken Tent." His strongest allegiance probably was to the quatrain with simple rhymes such as *abab* and *abcb*, and within its restrictions he was able to achieve an infinite variety, as in the aforementioned "Dust of Snow" and "Desert Places." Frost was never an enthusiast of free verse and regarded its looseness as something less than ideal, similar to playing tennis without a net. His determination to be "new" but to employ "old ways to be new" set him aside from the radical experimentalism of the advocates of *vers libre* in the early 20th century. On occasion Frost did employ free verse to advantage, one outstanding example being "After Apple-Picking," with its random pattern of long and short lines and its non-traditional use of rhyme. Here he shows his power to stand as a transitional figure between the old and the new in poetry. Frost mastered blank verse (*i.e.*, unrhymed verse in iambic pentameter) for use in such dramatic narratives as "Mending Wall" and "Home Burial," becoming one of the few modern poets to use it both appropriately and well. His chief technical innovation in these dramatic-dialogue poems was to unify the regular pentameter line with the irregular rhythms of conversational speech. Frost's blank verse has the same terseness and concision that mark his poetry in general.

*Assessment.* Frost was the most widely admired and highly honoured American poet of the 20th century. Amy Lowell thought he had overstressed the dark aspects of New England life, but Frost's later flood of more uniformly optimistic verses made that view seem antiquated. Louis Untermeyer's judgment that the dramatic poems in *North of Boston* were the most authentic and powerful of their kind ever produced by an American has only been confirmed by later opinions. Gradually, Frost's name ceased to be linked solely with New England, and he gained broad acceptance as a national poet.

It is true that certain criticisms of Frost have never been wholly refuted, one being that he was overly interested in the past, another that he was too little concerned with the present and future of American society. Those who criticize Frost's detachment from the "modern" emphasize the undeniable absence in his poems of meaningful references to the modern realities of industrialization, urbanization, and the concentration of wealth, or to such familiar items as radios, motion pictures, automobiles, factories, or skyscrapers. The poet has been viewed as a singer of sweet nostalgia and a social and political conservative who was content to sigh for the good things of the past.

Such views have failed to gain general acceptance, however, in the face of the universality of Frost's themes, the emotional authenticity of his voice, and the austere technical brilliance of his verse. Frost was often able to endow his rural imagery with a larger symbolic or metaphysical significance, and his best poems transcend the immediate realities of their subject matter to illuminate the unique blend of tragic endurance, stoicism, and tenacious affirmation that marked his outlook on life.

Over his long career Frost succeeded in lodging more than a few poems where, as he put it, they would be "hard to get rid of," and he can be said to have lodged himself just as solidly in the affections of his fellow Americans. For thousands he remains the only recent poet worth reading and the only one who matters.

(P.L.Ge.)

**BIBLIOGRAPHY.** *Selected Letters of Robert Frost*, ed. by Lawrance Thompson (1965); and *The Letters of Robert Frost to Louis Untermeyer*, ed. by Louis Untermeyer (1963), offer good coverage of his correspondence. Frank Lentricchia and Melissa Christensen Lentricchia, *Robert Frost: A Bibliography, 1913-1974* (1976), gives reliable data concerning the publication of Frost's works. The most complete biography is Lawrance Thompson, *Robert Frost*, 3 vol., vol. 3 coauthored with R.H. Winnick (1966-76). A fine early biography is Elizabeth Shepley Sergeant, *Robert Frost: Trial by Existence* (1960). William H. Pritchard, *Frost: A Literary Life Reconsidered*, 2nd ed. (1993), is a provocative revisionist biography. Philip L. Gerber, *Robert Frost*, rev. ed. (1982), provides a comprehensive introduction to the life and works. Elaine Barry (compiler), *Robert Frost on Writing* (1973), collects letters, prefaces, reviews, lectures, and interviews in which Frost offers ideas concerning the composition and purpose of poetry. George W. Nitchie, *Human Values in the Poetry of Robert Frost* (1960); and Reuben A. Brower, *The Poetry of Robert Frost* (1963), are excellent early critical studies. Richard Poirier, *Robert Frost: The Work of Knowing* (1977, reissued with a new afterword, 1990); and Judith Oster, *Toward Robert Frost: The Reader and the Poet* (1991), stand out among later studies. Norman N. Holland, *The Brain of Robert Frost* (1988), is a cognitive approach informed by psychological insights and exploring the working of the human mind through a close examination of Frost's poems. Edwin H. Cady and Louis J. Budd (eds.), *On Frost* (1991), provides an excellent introduction to critical reviews on Frost written by important critics between 1937 and 1990.

**Frost, Sarah Frances:** see Marlowe, Julia.

**frost-free season:** see growing season.

**frost point,** temperature, below 0° C (32° F), at which moisture in the air will condense as a layer of frost on any exposed surface. The frost point is analogous to the dew point, the temperature at which the water condenses in liquid form; both the frost point and the dew point depend upon the relative humidity of the air.

**frostbite,** a freezing of living tissue; frostbite occurs whenever heat loss from a tissue is sufficient to permit ice formation. The freezing-thawing process causes mechanical damage to cells (from ice), tissue dehydration, and local oxygen depletion. If not relieved, these conditions lead to disruption of the blood corpuscles, thrombosis (clotting) within the small blood vessels, and tissue gangrene.

**Conditions conducive to frostbite.** Frostbite can occur whenever the ambient temperature falls below 0° C (32° F). Without adequate food, clothing, or shelter, heat is lost successively from the interior of the body to the skin, to the layer of still, insulating air surrounding the skin, and finally to the ambient cold air. High-velocity wind blowing away the insulating air cover, as well as the wetting of the skin, hastens the outward transfer of heat. Thus ice fishermen, hunters, campers, mountaineers, and others exposed to wind and low temperatures may become victims of frostbite.

All too impressive is the injury and death toll from cold during time of war. Armies that suffered as much from the cold as from the enemy include Xenophon's Greeks in Armenia (400 BC), the Swedish troops of Charles XII in Ukraine (1708), and the army of George Washington at Valley Forge in America (1777-78). Most classic is the saga of the Napoleonic forces fleeing Russia (1812-13). Pursued by a relentless enemy in the dead of winter, driven onward without food, water, rest, adequate clothing or footwear, many

thousands of troops suffered frostbite or froze to death.

Three types of individual physical and health factors can contribute to frostbite. They are (1) conditions encouraging heat loss, (2) mechanical or physical impedance of circulation to the extremities, and (3) problems that decrease the ability of a person to cope with the cold.

Conditions encouraging heat loss are (1) the excessive intake of alcohol, causing capillary dilation, flushing, and dissipation of heat, (2) wet clothing, permitting outward heat conduction, (3) exposed flesh, (4) fever, with radiation of heat, (5) injury, with hemorrhage, anoxia, and shock, causing general body cooling, and (6) overexercise, as in forced survival marches, draining unreplaced calories and heat.

Factors that mechanically impede circulation to the extremities and thus favour cooling and subsequent freezing include (1) tight boots, gloves, or clothing, (2) blood vessel diseases or injuries that diminish the flow of blood to the extremities, causing local tissue oxygen depletion, and (3) constriction of small blood vessels as a result of drug action.

Conditions that decrease the ability of a person to avoid cold insult include (1) emaciation or fatigue, (2) dehydration, a major problem in the cold, with subsequent blood acidity, mental derangement, coma, and death, (3) neuromuscular disease, or previous freezing or nonfreezing cold injury, with resultant sensory loss, predisposing to further cold injury, and (4) psychosis from any cause, allowing behaviour contributory to freezing, with mental disorganization, loss of thermoregulation, and resultant fall of body temperature.

**Recognition and treatment.** Frostbite usually affects the toes, fingers, ears, and the tip of the nose first. Before thawing, the affected part is hard, cold, white, or bloodless. The skin is rigid and the depth of freezing difficult to determine. Frostbite is rendered more dangerous by the fact that there is no sensation of pain, and the victim may not even know that he has been frostbitten.

In dealing with frostbite, body temperature is usually restored to as near normal as possible before thawing. Under no circumstances should attempts be made to warm the affected area by rubbing or chafing it, since this can damage the cell structure of the frozen tissues. The old theory that a frostbitten area should be rubbed with snow or ice is similarly false and potentially harmful. Rapid thawing of the hands or feet in warm water baths is a presently favoured method of therapy. Thawing time is determined by the temperature of the bath and the depth of the freezing; thawing is complete when the tip of the extremity flushes pink or red. (If the affected area remains white after thawing, this means that the cold has so affected local blood vessels that normal circulation has not yet resumed.) After rapid thawing small blisters appear rapidly, spontaneously rupturing in 4 to 10 days. A castlike scab, often black, forms after the blisters rupture. Normal tissue may have already formed below. The thawed part is usually protected to avoid both refreezing and excessive heat. Neither bandages nor dressings are used, and the area is cleansed with benign soaps. Constant digital exercises are performed to preserve joint motion. Early surgical removal of unhealthy tissue (debridement) and amputation is avoided. Whirlpool action will debride devitalized tissues.

Antibiotics are used if necessary; toxoid booster injections are a recommended precaution. After thawing, further treatment is aimed at the prevention of infection and preservation of function.

The outlook is best when the frozen state is of short duration, when the thawing is by rapid rewarming, and when blisters develop early, pink and large, and extend to the tips of the hands or toes.

The outlook is uncertain when thawing is spontaneous, as at room temperature, when the frozen state is of long duration, and when the freezing is superimposed on top of a fracture or dislocation.

The outlook is poor when thawing is delayed, as in ice and snow, when thawing is by excessive heat (*i.e.*, greater than 46° C [115° F]), when the blisters are dark or hemorrhagic and do not extend to the distal tips, when a nonfreezing cold injury is followed by freezing, and when freezing, then thawing by any means, is followed by refreezing. The last two conditions are disastrous and almost always require amputation of the affected part.

Major complications after freezing, and following treatment, may be infection and tissue death, requiring amputation. Less tragic aftereffects are increased sweating, sensory loss, diminished subcutaneous fat pad of the toes and fingers, persistent deep pain, limitation of joint motion, and nail-bed changes. Other permanent effects include fixed scars, wasting of the small muscle, joint deformity, arthritic changes in bone, and neurovascular involvement in the extremities resulting in the inability to protect against lowered temperatures, coupled with increased sensitivity to cold.

**Frostbite prevention.** To prevent frostbite, clothing in cold weather should be dry, layered, and with warm, loose hand wear and footwear. Tight, restricting bands should not be worn. Exposed flesh should be protected from the wind: face masks, hoods, and earmuffs are helpful. In cold, an individual must remain alert, avoiding the excessive use of alcohol and drugs inhibiting mental or physical capability.

Should freezing follow an accident, major efforts must be made to avoid further heat loss in order to prevent death; and, in any situation in which freezing has occurred, thawing should be prevented if refreezing may take place.

**frosted bat,** any of certain bat species of the family Vespertilionidae (*q.v.*).

**froth flotation,** separation of minerals differing little in density but greatly in wettability by surfactant-active agents that stabilize a froth formed on the surface of an agitated suspension of the minerals in water. See flotation.

**frottage** (French: "rubbing"), in visual arts, technique of obtaining an impression of the

"Animal Head on a Pedestal," pencil frottage by Max Ernst, 1921-22; in the Kunstmuseum, Basel, Switz.

By courtesy of the Oeffentliche Kunstsammlung, Kupferstichkabinett, Basel, Switz. Karl August Burchhardt-Koehlin-Fonds

surface texture of a material, such as wood, by placing a piece of paper over it and rubbing it with a soft pencil or crayon, as for taking brass rubbings; the name is also applied to the impression so obtained. Frottage was used by Max Ernst and other members of the Surrealist movement, for whom it often provided the starting point for more elaborate compositions such as paintings and collages.

**frottola**, plural **FROTTOLE**. Italian secular song popular in the late 15th and early 16th centuries. Usually the frottola was a composition for four voice parts with the melody in the top line. Frottola could be performed by unaccompanied voices or by a solo voice with instrumental accompaniment. The frottola had chordal texture and clear-cut rhythm, usually in  $\frac{3}{4}$  or  $\frac{4}{4}$  metre. The voice parts had narrow ranges and frequently repeated voices. Its musical style was simple, in deliberate contrast to the complexity of more sophisticated vocal music of the period. The frottola, as it developed by 1530, was the direct antecedent of the 16th-century madrigal.

The frottola was aristocratic music, although popular tunes were sometimes incorporated. Under the patronage of Isabella d'Este, the frottola developed at the court at Mantua, and it also became popular at other courts of northern Italy, particularly at Ferrara and Urbino. Serafino dall'Aquila (d. 1500) was an important frottola poet. The most important composers of frottola were Bartolomeo Tromboncino (d. c. 1535) and Marchetto Cara (d. c. 1530). At times the same person wrote both text and music.

Frottola texts were usually of limited literary value, typically consisting of several six-line verses, each followed by a four-line refrain, using the same music.

The term frottola was also used for a class of compositions, some with specific poetic forms, including the *strambotto*, the *oda*, and the *barzelletta*. Ottaviano dei Petrucci, the first significant printer to use movable music type, printed 11 books of frottole in Venice between 1504 and 1514.

**Froude, James Anthony** (b. April 23, 1818, Dartington, Devon, Eng.—d. Oct. 20, 1894, Kingsbridge, Devon), English historian and biographer whose *History of England from the Fall of Wolsey to the Defeat of the Spanish Armada*, 12 vol. (1856–70), fundamentally altered the whole direction of Tudor studies. He was immensely prolific, producing also novels and essays.

Froude was, both at home and at the University of Oxford, which he entered in 1835, dominated by his elder brother Richard Hurrell Froude, famous himself as one of the founders of the Oxford Movement. Froude was influenced also by John Henry Newman, the future cardinal, who was one of his fellow students at Oriol College. After graduating in 1842, he broke with the movement and, with the appearance of *The Nemesis of Faith* in 1849, the third of his novels, which was in effect an attack on the established church, he was obliged to resign his fellowship at Exeter College. He thereafter made his living by his pen until in 1892 he returned to Oxford as regius professor of modern history.

In Froude's historical works there are numerous instances of his careless handling of his texts, yet there is no evidence of deliberate distortion. His errors derive partly from the tremendous speed at which he worked. But they resulted also from a more fundamental cause. To Froude the 16th century was the crucial period in English history, when the forces of liberty, as expressed by the Reformation, were struggling against the forces of darkness, as represented by the Roman Catholic church. This theme gives to all his work a

vigorous partisan quality. He believed indeed that the Anglo-Catholic revival of the 19th century was merely a later version of the same danger. It was his declared duty to open the eyes of his own generation to the perils that had been faced and overcome by the Tudors.

The other great influence upon his attitude to history was Thomas Carlyle, from whom Froude absorbed the doctrines of the role of the hero in history. Henry VIII was Froude's hero; and his portrait of him was wholly at variance with those drawn by Lord Macaulay, M.A.S. Hume, and John Lingard. Henry, according to Froude, was the man of courage and energy who guided the nation through its gravest crisis. Elizabeth I, by contrast, was a weak, uncertain ruler who needed Lord Burghley—the hero of the later volumes of his *History*—to save her from the consequences of her own follies.

Savage attacks by reviewers had no effect on Froude's methods as a historian or on his popularity with the reading public. There followed, among other works, *The English in Ireland in the Eighteenth Century*, 3 vol. (1872–74), *The Life and Letters of Erasmus*, 2 vol. (1894), and *English Seamen in the Sixteenth Century* (1895). But the great work of the later part of his life was his biography of Carlyle, which appeared in four volumes (1882–84), as well as an edition of Carlyle's papers, 2 vol. (1881). Here, too, he was severely handled by his enemies, again for his inaccuracy but also for his frank analysis of Carlyle's defects of character which, Froude claimed, as an honest biographer he must fully examine.

*A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume*

**Froude, Richard Hurrell** (b. March 25, 1803, Dartington, Devon, Eng.—d. Feb. 28, 1836, Dartington), Anglican churchman and a leader of the Oxford Movement, which sought to reintroduce High Church, or "catholic," thought and practice into the Church of England.

Froude was educated at Oriol College, Oxford (B.A., 1824; M.A., 1827), where he met John Keble, and was tutor of his college (1827–30), when he met John Henry Newman. He was ordained in 1829. His importance thenceforth lay in two associated fields. First, he became a vocal opponent of the Erastianism and liberalism that seemed to him to threaten the Anglican church's independence and authority. Second, he became intimate with Newman, assisted his conversion to High Church views, and by bringing him into close touch with Keble formed the team that began the *Tracts for the Times* and thus started the Oxford Movement in 1833. He died, age 32, of tuberculosis.

**Froude, William** (b. Nov. 28, 1810, Dartington, Devon, Eng.—d. May 4, 1879, Simonstown, S.Af.), English engineer and naval architect who influenced ship design by developing a method of studying scale models propelled through water and applying the information thus obtained to full-size ships. He discovered the laws by which the performance of the model could be extrapolated to the ship when both have the same geometrical shape. A similar technique later was used by pioneers in aerodynamics.

Educated at Westminster School and Oriol College, Oxford, Froude worked as a railway engineer until 1846, when he began his work on ship hydrodynamics. He learned that rolling of ships can be reduced with a deep bilge keel, a finlike projection stretching horizontally along both sides of a ship below the waterline. The device was adopted by the Royal Navy.

After serving in 1868 on a committee to

study naval design, he proposed to the British Admiralty a series of experiments using models to determine the physical laws governing full-scale ships. His proposals were accepted in 1870, and at Froude's home near Torquay a model-testing tank was built. He discovered that the chief components of resistance to motion are skin friction and wave formation.

**Froude number**, in hydrology and fluid mechanics, dimensionless quantity used to indicate the influence of gravity on fluid motion. It is generally expressed as  $F = v/(gd)^{-1/2}$ , in which  $d$  is depth of flow,  $g$  is the gravitational acceleration (equal to the specific weight of the water divided by its density, in fluid mechanics),  $v$  is the celerity of a small surface (or gravity) wave, and  $F$  is the Froude number. When  $F$  is less than 1, small surface waves can move upstream; when  $F$  is greater than 1, they will be carried downstream; and when  $F = 1$  (said to be the critical Froude number), the velocity of flow is just equal to the velocity of surface waves. The Froude number enters into formulations of the hydraulic jump (rise in water surface elevation) that occurs under certain conditions, and, together with the Reynolds number ( $q.v.$ ), it serves to delineate the boundary between laminar and turbulent flow conditions in open channels.

**Fructidor, Coup of 18** (Sept. 4, 1799), the purge of ultraconservatives from the Corps Législatif and other posts during the period of the Directory in France. The Directory, fearing that it was losing favour in the country, called upon Napoleon Bonaparte to send a general to command troops guarding the legislature at the Tuileries. On 18 Fructidor, year V (Sept. 4, 1799), General Pierre-François Charles Augereau, commanding the troops, purged more than 130 royalists and counter-revolutionaries from the Corps Législatif; and many deputies, journalists, nonjuring priests, and other individuals were deported to Guiana in South America, including the director, the Marquis de Barthélemy. The royalists were thus once more overthrown—but with them the republican constitution itself. The coup still further confirmed the new power of the army and thus went far in preparing the way for the military despotism of Napoleon.

**fructose**, a member of a group of carbohydrates known as simple sugars, or monosaccharides. Fructose, along with glucose, occurs in fruits, honey, and syrups; it also occurs in certain vegetables. It is a component, along with glucose, of the disaccharide sucrose, or common table sugar. Phosphate derivatives of fructose (e.g., fructose-1-phosphate, fructose-1,6-diphosphate) are important in the metabolism of carbohydrates.

**fructosuria**, disturbance of fructose metabolism resulting from a hereditary disorder or intolerance. Normally, fructose is first metabolized in the body to fructose-1-phosphate by a specific organic catalyst or enzyme called fructokinase. In fructosuria this particular enzyme is defective, and the concentration of fructose increases in the blood and urine. There are no other clinical manifestations or disabilities, and the condition is compatible with normal life expectancy.

**Frueh, Al**, byname of ALFRED FRUEH (b. 1880, Lima, Ohio, U.S.—d. Sept. 14, 1968, Sharon, Conn.), American cartoonist and caricaturist for *The New Yorker* magazine from 1925 to 1962.

Reared variously to be a farmer and then a brewer and also studying at a business school in his home town (learning shorthand), Frueh turned to cartooning professionally after being hired by the *St. Louis Post-Dispatch* (1904–08) in its art department. After a trip to Europe in 1909, he worked for the *New York World* (1910–12, 1914–25) and then, in 1925, contributed two cartoons for the very first is-

"My Fair Lady," drawing by Al Frueh, 1956, with portraits of cast members (left to right) Rex Harrison, Stanley Holloway, and Julie Andrews

Drawing by Frueh. © 1956, 1984 The New Yorker Magazine, Inc

sue of *The New Yorker* and then the cover cartoon for its second issue. He remained a contributor to *The New Yorker* until the age of 82, producing chiefly caricatures of the Broadway theatre scene.

**Fruehauf Trailer Corporation**, also called (1918–63) FRUEHAUF TRAILER COMPANY, or (1963–89) FRUEHAUF CORPORATION, American corporation engaged in the manufacture and sale of truck trailers. Headquarters are in Indianapolis, Ind., U.S.

The founder, August Charles Fruehauf (1868–1930), began as a blacksmith and carriage builder around Detroit. In 1914, at the request of a local lumber merchant, he built a trailer to carry the merchant's pleasure boat, to be hauled by a Ford automobile. The trailer was so successful that the merchant had Fruehauf build similar haulers for his lumber, which Fruehauf came to call "semi-trailers." Business boomed, and four years later, in 1918, Fruehauf incorporated the Fruehauf Trailer Company. Over the next few decades the company prospered and introduced several new concepts in trailer design and size—first under the founder and then under his son Harvey Charles Fruehauf (1896–1968).

In 1953 Harvey's younger brother Roy August Fruehauf (1908–65) wrested control of the company but inaugurated financial and tax practices that led to federal indictments and company instability. The young Fruehauf was removed in 1959, but his successors, William Grace and Robert Rowan, while expanding and diversifying the company's operations, also exhibited questionable management practices. A leveraged buyout in 1986 by the company's management left Fruehauf burdened with debt, and in 1989 the company was broken up and sold, though one segment, the truck trailer unit, retained the name Fruehauf Trailer Corporation.

**fruit**, in its strict botanical sense, the fleshy or dry ripened ovary of a plant, enclosing the seed or seeds. Thus, apricots, bananas, and grapes, as well as bean pods, corn grains, tomatoes, cucumbers, and (in their shells) acorns and almonds, are all technically fruits. Popularly, however, the term is restricted to the ripened ovaries that are sweet and either succulent or pulpy. The cultivation and processing of fruits are major industries worldwide.

A brief treatment of fruit follows. For information on particular fruits, see apple, banana, orange, peach, and so on. Various aspects of fruit are treated in several articles in the MACROPAEDIA. For treatment of the fruit as a reproductive structure, see Reproduction and Reproductive Systems. For treatment of the cultivation of fruits, see Farming and Agricultural Technology. For treatment of the nutrient composition and processing of fruits, see Food Processing.

A fruit is a mature ovary and its associated parts. It usually contains seeds, which have developed from the enclosed ovule after fertilization, although development without fertilization, called parthenocarp, is known, for example, in bananas. The principal botanical purpose of the fruit is the protection and dissemination of the seed.

Fertilization induces various changes in a flower: the anthers and stigma wither, the petals drop off, and the sepals may be shed or undergo modifications; the ovary enlarges, and the ovules develop into seeds, each containing an embryo plant. (See also seed.)

There are two broad categories of fruits: fleshy fruits, in which the pericarp and accessory parts develop into succulent tissues, as in tomatoes, oranges, and cherries; and dry fruit, in which the entire pericarp becomes dry at maturity. Fleshy fruits include (1) the berries, such as tomatoes, oranges, and cherries, in which the entire pericarp and the accessory parts are succulent tissue; (2) aggregate fruits, such as blackberries and strawberries, which form from a single flower with many pistils, each of which develops into fruitlets; and (3) multiple fruits, such as pineapples and mulberries, which develop from the mature ovaries of an entire inflorescence. Dry fruits include the legumes, cereal grains, capsulate fruits, and nuts.

In general, the chief concerns of fruit cultivation are the propagation and improvement of varieties; the improvement of the microclimatic conditions and soil conditions of the site; the design of planting and spacing systems; the development of training and pruning techniques; soil management, irrigation, and fertilization; pollination; thinning; pest control; and the development of harvesting and postharvest practices.

Fruits are important sources of dietary fibre and vitamins (especially vitamin C). Although fresh fruits are subject to spoilage, their shelf life can be extended by refrigeration or by the removal of oxygen from their storage or packaging containers. Fruits can be processed into juices, jams, and jellies and preserved by dehydration, canning, fermentation, and pickling.

**fruit bat**, any of numerous tropical Old World bats of the family Pteropodidae (*q.v.*).

**fruit fly**, any two-winged insect of either the family Trypetidae or the family Drosophilidae (order Diptera) whose larvae feed on fruit or other vegetative matter. Insects of the family Trypetidae are often referred to as large fruit flies, and those of the Drosophilidae as small fruit flies, or vinegar flies. (See vinegar fly.)

The fruit fly has wings that are banded or spotted with brown. Many species attack cultivated fruits, causing damage that may lead to significant economic losses. Some fruit flies, such as the European celery fly, are leaf miners; others burrow in plant stems. A species of *Eurosta* causes a common stem gall (swelling) of goldenrod.

Fruit fly (Trypetidae)  
E.S. Ross

The Mediterranean fruit fly (*Ceratitis capitata*) lays as many as 500 eggs in citrus fruits (except lemons and sour limes). The larvae tunnel into the flesh of the fruit and make it unfit for human consumption. Discovered in Florida in 1929, the Mediterranean fruit fly was thought to have been eradicated in the United States by 1930 but reappeared in 1956 and in the early 1960s and again, in California, in the 1980s. Because of this pest, worldwide quarantine laws were formed to regulate the entry of fruits into countries.

The apple maggot, the larva of *Rhagoletis pomonella*, burrows into apples, causing the fruit to become spongy and discoloured. This species and the closely related cherry fruit fly (*R. cingulata*) cause extensive losses in the northeastern United States.

Other widespread pests of this family include the Mexican fruit fly (*Anastrepha ludens*), which attacks citrus crops; the Oriental fruit fly (*Dacus dorsalis*), which infests many kinds of subtropical fruits; and the olive fruit fly (*Dacus oleae*), which destroys olives in the Mediterranean region. Control methods vary with the species involved and include spraying of fruits with insecticides during the egg-laying season, destruction of infested fruit, and control by parasites.

**fruit spot**, symptom of plant disease, usually caused by fungi and bacteria. A spot is a definite, localized area. Spots frequently enlarge and merge to form a rot, a softening discoloration and often a disintegration of tissue.

Fruit spot (*Penicillium expansum*) on pear  
Carlo Bevilacqua—SCALA from Art Resource

All fruits are susceptible; infection commonly starts at a wound, the stem end, or the underside. Bacterial decays that are caused by *Erwinia* and some *Pseudomonas* species are watery to mushy and putrid and follow injuries. Other bacterial and fungal decays (except *Pythium* and *Phytophthora*) are generally firm and dry. Fruit-infecting organisms may attack other plant parts. Insects commonly transmit the infecting microorganisms and provide the entry wounds. Spots and rots develop rapidly in warm, moist storage. See also rot; scab; sooty mold.

**fruitworm beetle**, any of a few genera of insects in the family Byturidae (order Coleoptera) whose larvae feed on fruit. A common example of this family of small, hairy, oval beetles is the raspberry fruitworm (*Byturus rubi*). The small, pale larva, which is covered with short fine hairs, attacks the raspberry fruit. The adult, which ranges in colour from reddish yellow to black, is about 4 mm (0.16 inch) long. It feeds on the flowers and leaves of raspberry and blackberry plants.

**Frumentius**, SAINT, Amharic ABBA SALAMA (fl. 4th century; feast day October 27), Syr-

ian apostle who introduced Christianity into Ethiopia. As first bishop of its ancient capital, Aksum, he structured the emerging Christian church there in the orthodox theology of the Alexandrian school during the 4th-century controversy over Arianism.

A student of philosophy from Tyre, Frumentius and a colleague, Aedesius, were captured by Ethiopians in about 340. They became civil servants at the court of the Aksumite king Ezana, whom Frumentius converted. On the death of the monarch, Frumentius became the royal administrator and tutor to the crown prince and was empowered to grant freedom of religious expression to visiting Christian merchants from the Roman Empire.

After fulfilling his regency Frumentius visited Athanasius, bishop of Alexandria, in about 347. Athanasius ordained Frumentius bishop and commissioned him to initiate the cultural adaptation of Greek Christianity's biblical-liturgical texts to Ethiopic symbols and language. The link between the Egyptian Coptic and Ethiopian churches having thus been established, Frumentius, despite the enmity of the Byzantine Roman emperor Constantius II (337–361), repudiated the Arians. The 4th-century church historian Rufinus of Aquileia, by meeting Aedesius later at Tyre, was able to document Frumentius' achievements, noting that the Ethiopians addressed him as *abuna*, or "Our Father," a title that is still used for the patriarch of the Ethiopian Orthodox Church.

**Frunzberg, Georg von**, Frunzberg also spelled FREUNDSBERG, or FRONSBERG (b. Sept. 24, 1473, Mindelheim Castle, near Memmigen [Germany]—d. Aug. 20, 1528, Mindelheim Castle), German soldier and devoted servant of the Habsburgs, who fought on behalf of the Holy Roman emperors Maximilian I and Charles V.

Frunzberg, detail of an oil painting on wood by Christoph Amberger, c. 1520; in a private collection, Kirchheim, Ger.

Fotohaus Sepp Hartmann

In 1499 Frunzberg took part in Maximilian's struggle against the Swiss, and, in the same year, he was among the imperial troops sent to assist Ludovico Sforza, duke of Milan, against the French. Still serving Maximilian, he took part in 1504 in the war over the succession to the duchy of Bavaria-Landshut, and afterward he fought in the Netherlands. Frunzberg is often called the "father of the Landsknechte," because he played a prominent part in the organization of that formidable mercenary infantry, armed with pike and sword, which became Maximilian's most powerful striking force. As commander of the Landsknechte, Frunzberg was of great service to the empire in 1509, 1513, and 1514 against the Venetians and the French. When the struggle between France and the empire was renewed, he took part in the invasion of Picardy (1521). Proceeding to Italy, he brought most of Lombardy

under the influence of Charles V through his victory at Bicocca in April 1522. He was partly responsible for the great victory over the French at the Battle of Pavia in February 1525. Returning to Germany, he helped to suppress the peasants' revolt, using on this occasion diplomacy as well as force.

**Frunze** (Kyrgyzstan): see Bishkek.

**Frunze, Mikhail Vasilyevich** (b. Jan. 21 [Feb. 2, New Style], 1885, Pishpek, Kirgiziya, Russian Empire [now Bishkek, Kyrgyzstan]—d. Oct. 31, 1925, Moscow, Russia), Soviet army officer and military theorist, regarded as one of the fathers of the Red Army.

Frunze took part in the Moscow insurrection in 1905 and, after frequent arrests for revolutionary activity, escaped in 1915 to conduct agitation in the Russian army, first on the western front and, after the February 1917 Revolution, in Belorussia (now Belarus). He became one of the outstanding commanders of the Civil War, commanding, in turn, the eastern front against Admiral A.V. Kolchak in 1919 and the southern front, where General P.N. Wrangel was routed, in 1920. He became deputy people's commissar for war in March 1924 and replaced Leon Trotsky as people's commissar for war in January 1925. In 1924 he also became a candidate member of the Politburo.

Frunze was one of a group that opposed Trotsky's views during the Civil War and, in consequence, won the support of Joseph Stalin, who ensured his advance after 1921. He was the author of the "unitary military doctrine," according to which the army should be trained throughout in a spirit of offensive action, united by its ideology and by its determination to carry out the task of the Communist Party—the promotion of world revolution. This could not, in his view, be achieved so long as the army was commanded by officers of the old imperial army, whom Trotsky, of practical necessity, had put in command of the new Red Army after 1918. Frunze asserted that the form of the Soviet military establishment should flow directly from the revolutionary and class character of the Soviet state. He helped lay the basis for a permanent and efficient peacetime Soviet military machine by introducing peacetime compulsory military service and by standardizing military formations, drills, and uniforms.

**Fry, Christopher**, original name CHRISTOPHER HARRIS (b. Dec. 18, 1907, Bristol, Gloucestershire, Eng.—d. June 30, 2005, Chichester, West Sussex), British writer of verse plays.

Christopher Fry, 1950  
BBC Hulton Picture Library

Fry adopted his mother's surname after he became a schoolteacher at age 18, his father having died many years earlier. He was for many years an actor, director, and writer of revues and plays before he gained fame as a

playwright with *The Lady's Not for Burning* (1948), an ironic medieval comedy whose heroine is charged with being a witch. *A Phoenix Too Frequent* (1946) retells a tale from Petronius Arbiter. *The Boy with a Cart* (1950), a story of Saint Cuthman, is a legend of miracle and faith in the style of the mystery plays. *A Sleep of Prisoners* (1951) and *The Dark Is Light Enough* (1954) explore religious themes. After many years of translating and adapting plays, Fry wrote *A Yard of Sun*, which was produced in 1970. He also collaborated on the screenplays of the epic films *Ben Hur* (1959) and *Barabbas* (1962), and he wrote both radio and television plays.

His *Can You Find Me: A Family History* was published in 1978.

**Fry, E. Maxwell; and Drew, Jane**, in full EDWIN MAXWELL FRY and DAME JANE BEVERLY DREW (respectively b. Aug. 2, 1899, Wallasey, Cheshire, Eng.—d. Sept. 3, 1987, Cotherstone, Durham; b. March 24, 1911, Thornton Heath, Surrey—d. July 27, 1996, Cotherstone, Durham), British architects, husband and wife (from 1942), who pioneered in the field of modern tropical building and town planning.

Maxwell Fry, one of the earliest British adherents to the modern movement, was trained at the Liverpool University School of Architecture. In 1924 he joined the town-planning firm of Adams and Thompson in London. Renouncing classical architecture, he wrote that he saw "no place for it in a technocratic world." His early work shows the strong influence of Mies van der Rohe, a leading proponent of the International style in architecture.

Jane Drew, a graduate of the Architectural Association School, London, did specialist studies on kitchen planning for the British Commercial Gas Corporation (1941–43). She married Maxwell Fry in 1942. From 1944 to 1946 she was assistant town-planning adviser to the resident minister for the British West African colonies, while Fry served as the chief town-planning adviser there. In 1946 the two formed the firm of Fry, Drew and Partners, London, specializing in large-scale planning for tropical countries. Among the many tropical buildings they designed are those of the University of Ibadan, Nigeria (1953–59). Their books *Village Housing in the Tropics* (1947; with Harry L. Ford) and *Tropical Architecture in the Humid Zone* (1956) are considered standard works.

The French architect Le Corbusier invited Fry and Drew to join him in 1951 on the project to build Chandigarh, the new capital city of the state of Punjab in India. In their houses there, Fry and Drew utilized the sun-sheltering properties of canopies and deep recesses.

Among Drew's best-known works are the Institute of Contemporary Arts, London (1964), the School for the Deaf, Herne Hill, London (1968), and the Open University, Milton Keynes (1969–77). Fry's important written works are *The Bauhaus and the Modern Movement* (1968) and *Art in a Machine Age* (1969). Drew was knighted in 1996.

**Fry, Elizabeth**, née GURNEY (b. May 21, 1780, Norwich, Norfolk, Eng.—d. Oct. 12, 1845, Ramsgate, Kent), British Quaker philanthropist and one of the chief promoters of prison reform in Europe. She also helped to improve the British hospital system and the treatment of the insane.

The daughter of a wealthy Quaker banker and merchant, she married (1800) Joseph Fry, a London merchant, and combined her work with the care of a large family. Unwearingly attending to the poor, she was acknowledged as a "minister" by the Society of Friends (1811) and later traveled in Scotland, northern England, Ireland, and much of Europe. There she inspected prisons and wrote reports. Her recommendations for Newgate Prison, for instance, included separation of the sexes, clas-

sification of criminals, female supervision for women, adequate provision for religious and secular instruction, and useful employment. Even in her lifetime her suggestions were increasingly acted upon throughout most of Europe.

**Fry, Roger (Eliot)** (b. Dec. 14, 1866, London, Eng.—d. Sept. 9, 1934, London), English art critic and artist, best known as the champion of the movement to which he gave the name Postimpressionism.

Fry was born into a Quaker family and was educated at the University of Cambridge for a career in science. His interest in art grew, however, and he studied painting in Italy and also began to lecture on art. His first book, *Giovanni Bellini*, was published in 1899. Thereafter he published art criticism, and in 1905 his edition of Joshua Reynolds' *Discourses* was published. From 1905 to 1910 he was director of the Metropolitan Museum of Art in New York City.

Fry first came into contact with the work of the French painter Paul Cézanne in 1906, and the experience changed the course of his life. He began to publish articles on the works of Cézanne, Paul Gauguin, Henri Matisse, and Vincent van Gogh, for in these painters he saw a merging of the structural understanding of the classical artists with the colour explorations of the Impressionists. Upon his return to London, Fry became associated with the Bloomsbury group. In November 1910 he organized for the Grafton Galleries the first of two painting exhibitions that were to revolutionize aesthetics in England. The uproar over "Manet and the Post-Impressionists" was considerable; it removed Fry from the ranks of traditional and academic critics and propelled him into the vanguard of art criticism. A second exhibition of a similar nature was opened in October 1912.

In 1913, following a precedent that had been set by William Morris and the Arts and Crafts Movement, Fry organized a group of young artists into a collective called the Omega Workshops, a place for them to design, create, and decorate everyday functional objects (such as drapery, furniture, and china). Omega remained in operation until 1919.

Fry continued to lecture, travel, and paint throughout his life. His legacy is a body of art criticism and theory that includes *Vision and Design* (1920), *Transformations* (1926), *Cézanne* (1927), *Henri Matisse* (1930), and several other collections of lectures. In 1933 he was appointed Slade professor of fine art at Cambridge.

**BIBLIOGRAPHY.** Virginia Woolf, *Roger Fry* (1940, reissued 1976); Frances Spalding, *Roger Fry: Art and Life* (1980).

**Frycz-Modrzewski, Andrzej** (writer): see Modrzewski, Andrzej.

**Frýdek-Místek**, city, Severomoravský kraj (region), Czech Republic. It lies along the Ostrava River just south of Ostrava. The town is dominated by the steeple of Frýdek Castle, which was originally a Gothic royal castle but was reconstructed during the 17th and 18th centuries. Also of interest are the twin-tower 18th-century Baroque church and the small St. Jodocus Church. The town is within the sphere of influence of the Ostrava industrial region, with coal and iron deposits in the surrounding area, and heavy industry dominates its economy. Rolled steel, machinery, and cotton textiles are the principal manufactures. Pop. (1991 prelim.) 65,067.

**Frye, Northrop**, in full HERMAN NORTHROP FRYE (b. July 14, 1912, Sherbrooke, Que., Can.—d. Jan. 23, 1991, Toronto, Ont.), Canadian educator and literary critic, author of influential theories of criticism.

Frye was educated at the University of Toronto, Emmanuel College in Toronto, and Merton College, Oxford. He taught at Victoria

College from 1939, became chairman of the English department there in 1952, and served as principal (1959–67) and chancellor (from 1978) of the college. He was also a visiting professor in many American universities.

In 1947 he published *Fearful Symmetry: A Study of William Blake*, which was a sweeping and erudite study of Blake's visionary symbolism. In *Anatomy of Criticism* (1957), he analyzed various modes of literary criticism and stressed the recurring importance of archetypal symbols in literature. In later works Frye studied T.S. Eliot (1963), John Milton's epics (1965), Shakespearean comedy (1965) and tragedy (1967), and English Romanticism (1968). *The Stubborn Structure: Essays on Criticism and Society* appeared in 1970, and *The Great Code: The Bible and Literature*, a study of the mythology and structure of the Bible, was published in 1982. Frye's other critical works similarly emphasize the existence of group myths in literature and the systematic classification of literary symbols, genres, and criticism.

**frying**, the cooking of food in hot fats or oils, usually done with a shallow oil bath in a pan over a fire or as so-called deep fat frying, in which the food is completely immersed in a deeper vessel of hot oil. Because the food is heated through a greasy medium, some authorities consider frying to be technically a dry-heat cooking process.

The technique of frying is ancient, ubiquitous, and highly versatile; it has been used since antiquity and in most cultures to prepare meats and fish, vegetables, and breads. This popularity, together with the fairly low cost of large-scale frying, made fried foods the staples of the late 20th-century fast-food industry.

Fatty meats such as bacon and ground beef are usually fried in their own rendered fat. Relatively lean meats, fish, and vegetables are often floured or dipped in batter before being fried. More delicate cooking often calls for meats and vegetables to be sautéed, that is, lightly browned in a small amount of butter, light shortening, or oil. In addition to meat drippings, butter, and lard, once easily rendered in the home, commercially produced corn, peanut, and other seed oils are common frying mediums.

**FSH:** see follicle-stimulating hormone.

**Ft.:** see under Fort.

**fu**, Pinyin FU, type of Chinese bronze vessel produced largely in the middle Chou period (c. 900–c. 600 BC), as well as a type of bronze

Bronze fu with cover, 5th–3rd century BC, Eastern Chou dynasty; in the Art Institute of Chicago

By courtesy of the Art Institute of Chicago, Lucy Maud Buckingham Collection

ax made during the Shang (18th–12th century BC) and Chou (1111–255 BC) periods. Rectangular in shape and divided into two parts, the vessel is supported by angular feet at each corner; the lid is almost a duplicate of the bottom (in principle much like the *tui* [q.v.]). The rather squat shape and the minimal decoration are typical of the middle Chou period.

The cast broad ax may have a tang, or shaft-

hole, for the attachment of a handle, which may be decorated with animal motifs. The shape of the blade varies, but it generally is spatulate with a subtly arched and honed cutting edge. Probably the ax was used most often as a badge or emblem of authority; the ax motif is commonly found among the symbolic patterns on imperial robes of later periods.

**fu**, Chinese literary form combining elements of poetry and prose. Developing from the *Li sao* of Ch'ü Yüan (c. 343–c. 289 BC) during the Han dynasty (206 BC–AD 220), the *fu* was used for description and exposition, in contrast to the more subjective, lyrical *sao*. Its prosody was freer than that of the *sao*, the rhyme pattern being less restrictive. The elements of the *fu* form include a long line, caesura, and the use of balanced parallel phrases. The use of rhyme removes the *fu* from the area of pure prose and places it somewhere between poetry and prose. During Han times it was often abused for purposes of trivial and hackneyed description and was generally characterized by an endless piling up of words, although this technique was used quite skillfully by some writers. Hundreds of years later, during the Sung dynasty (960–1279), the *fu* was enriched by the skill of Ou-yang Hsiu (1007–72) and Su Tung-p'o (1036–1101), who made it more prose than poetry and used it to express philosophical concerns.

**Fu-an**, Pinyin FU'AN, city in northeastern Fukien sheng (province), China. It is situated on the east bank of the Chiao River, with highway communications running north into Chekiang and south along the coast to Fu-chou, some 90 miles (150 km) away. It is in an area of Fukien that was developed comparatively late, since it is somewhat less productive than the south of the province. Fu-an is above all a market for the tea produced in the area. Although tea production was neglected after the collapse of the Fu-chou tea trade at the end of the 19th century, tea today constitutes almost half of the income of the inhabitants. In the early 1950s, machine-processing plants were established at Fu-an, which also has a small engineering works. Pop. (mid-1980s est.) 10,000–50,000.

**Fu-chou**, Pinyin FUZHOU, conventional FOOCHEW, city near the east-central coast of Fukien sheng (province), China. It is the capital of the province. Fu-chou is situated on the north bank of the estuary of Fukien's largest river, the Min River, which gives access to the interior and to the neighbouring provinces of Kiangsi and Chekiang.

Fu-chou was one of the first places in Fukien to be settled. At the beginning of the 2nd century BC it was called Tung-ye and was the capital of the non-Chinese kingdom of Yüeh. After Han Wu Ti subjugated the area, it became the seat of Yeh county. In the 1st century AD its name was changed to Hou-kuan, and it became the military seat for the eastern coastal area. With the Sui conquest of southern China in 581, it was renamed Min county, and under the T'ang dynasty (618–907) it became the seat of Fu-chou prefecture. After the An Lu-shan rebellion of 755 it became the seat of the civil governor of Fukien; and in 789 the prefectural city was divided into two counties, Min and Hou-kuan. In the 9th and 10th centuries the population of Fukien as a whole rapidly increased.

Briefly the capital of the independent kingdom of Min from 909 to 944, Fu-chou has remained the capital of Fukien ever since. In Sung times (960–1279) much overseas trade was concentrated at Fu-chou, which also became an important cultural centre for the empire as a whole. Fu-chou prospered from the 16th to the 19th century, and its prosper-

ity reached its height when it was opened as a treaty port after the Anglo-Chinese Opium War of 1839–42. It subsequently became the chief port for the tea trade, being much nearer to the producing districts than Canton, to which tea had to be shipped overland. The eclipse of the Canton tea trade was completed when the Taiping Rebellion (1850–64) disrupted the overland route. With the decline of the tea trade, however, Fu-chou's export trade fell by half between 1874 and 1884; tea was gradually rivaled by exports of timber, paper, and foodstuffs.

In 1867 the port was the site of one of China's first major experiments with Western technology, when the Fu-chou Navy Yard was established; a shipyard and an arsenal were built under French guidance, and a naval school was opened. A naval academy was also established at the shipyard, and it became a centre for the study of Western languages and technical sciences. The academy, which offered courses in English, French, engineering, and navigation, produced a generation of Western-trained officers, including the famous scholar-reformer Yen Fu (1854–1921).

The yard was established as part of a program to strengthen China in the wake of the country's disastrous defeat in the trading conflict known as the second Opium War (1856–60). But most talented students continued to pursue a traditional Confucian education, and by the mid-1870s the government began to lose interest in the shipyard; it had trouble securing funds and declined in importance. Fu-chou remained essentially a commercial centre and a port until World War II; it had relatively little industry. The port was occupied by the Japanese during 1940–45.

Since 1949, Fu-chou has grown considerably; its communications have been improved by the clearing of the Min River for navigation by medium-sized craft upstream to Nan-p'ing. In 1956 the railway linking Fu-chou with the interior of the province and with the main Chinese railway system was opened. The port, too, has been improved; Fu-chou itself is no longer accessible to seagoing ships, but Lo-hsing-t'a anchorage and another outer harbour at Kuan-t'ou on the coast of the East China Sea have been modernized and improved. The chief exports are timber, fruits, paper, and foodstuffs.

Industry is supplied with power by a grid running from the Ku-t'ien hydroelectric scheme in the mountains to the northwest. The city is a centre for industrial chemicals and has food-processing, timber-working, engineering, papermaking, printing, and textile industries. A small iron and steel plant was built in 1958. In 1984 Fu-chou was designated one of China's "open" cities in the new open-door policy inviting foreign investments.

Handicrafts remain important, and the city is famous for its lacquer and wood products. Among Fu-chou's institutions of higher learning are Fukien Medical College, Fu-chou University, Fukien Normal University, Fukien Agricultural College, and a research institute of the Chinese Academy of Science. Pop. (1999 est.) 1,057,372.

**Fu-ch'un River**, Chinese (Wade-Giles) FU-CH'UN CHIANG, or (Pinyin) FUCHUN JIANG, river flowing through Chekiang province, China. The lower course and estuary discharging at Hang-chou into Hang-chou Bay are called the Ch'ien-t'ang River. Above Hang-chou, as far as T'ung-lu, it is called the Fu-ch'un River, and the section above T'ung-lu is known as the T'ung River. Near Chien-te the main river is formed by the junction of two separate river systems.

The westerly system is the Hsin-an River, which flows from southern Anhwei province,

where it rises in the Huang Mountains near She-hsien. This tributary flows through deep, gorgelike valleys in the rugged, hilly country of the Anhwei-Chekiang border. In the late 1950s this river was dammed above Chien-te to establish the Hsin-an River dam and hydroelectric project, forming a large lake.

The southern and eastern sections of the system are drained by the Lan River. At Lanhsi this is formed by the junction of two rivers, the Chin-hua River system, flowing from central Chekiang to the east, and the Ch'u River, which drains the mountains of the Chekiang-Kiangsi and Chekiang-Fukien border areas.

The Fu-ch'un River system provides the major routes from the Hang-chou and Shanghai area into inland Chekiang, northern Fukien, and Kiangsi, and it was the route by which Southeast China was largely colonized. The rivers themselves, however, are of limited use for navigation. Small steamers can travel as far as T'ung-lu, while river junks can reach Ch'ang-shan (on the Ch'u River) and Chin-hua (on the Chin-hua River). The role of the river has been greatly reduced since the construction of railways in the region.

The mouth of the Fu-ch'un River is famous for its tidal bore, sometimes as much as 20 feet (6 m) high, caused by tidal action in the funnel-shaped Hang-chou Bay. The length of the Fu-ch'un River is estimated to be 239 miles (385 km), and its drainage area is estimated at 16,456 square miles (42,621 square km).

**Fu Hsi**, Pinyin FU XI, formally (Wade-Giles romanization) T'AI HAO (Chinese: "The Great Bright One"), also called PAO HSI, or MI HSI, first of China's mythical emperors. His miraculous birth, as a divine being with a serpent's body, is said to have occurred in the 29th century BC. Some representations show him as a leaf-wreathed head growing out of a mountain or as a man clothed with animal skins. Fu

Fu Hsi, painting on silk; in the National Palace Museum, Taipei

By courtesy of the National Palace Museum, Taipei

Hsi is said to have discovered the famous Chinese trigrams used in divination and thus to have contributed, in some uncertain way, to the development of writing. He domesticated animals, taught his people to cook, to fish with nets, and to hunt with weapons made of iron. He likewise instituted marriage and offered the first open-air sacrifice to heaven. A stone tablet dated AD 160 depicts him with Nü Kua, a frequent companion, who was either his wife or sister.

**Fu-hsien** (China): see Wa-fang-tien.

**Fu-hsin**, Pinyin FUXIN, city, northwestern Liaoning *sheng* (province), China. It is located near the border with the Inner Mongolian Autonomous Region and serves as a centre for the administration of the large Mongolian population of the border area. Until 1902 the border area remained a pasture ground reserved for the Mongolians. It was legally opened to Chinese colonization in that year, although many settlers had already arrived. Fu-hsin became a market centre on the border between the agricultural zone occupied by Chinese peasants and the pastoral zone inhabited by the Mongolians. During the Japanese occupation of Manchuria (1931–45), important coal deposits were discovered in the area. The mines were badly damaged during the later stages of World War II, and production virtually ceased, but in the early 1950s the mines were reconstructed and reequipped with extensive Soviet aid. The coal fuels a very large thermal generating plant, also constructed with Soviet aid in the mid-1950s. This power facility is linked with the south Manchuria power grid system. The surrounding areas also have large reserves of iron ore. Pop. (1999 est.) 682,966.

**Fu Hsing**, Pinyin FU XING, in Chinese mythology, star god of happiness, one of the three stellar divinities known collectively as Fu-Shou-Lu. He is one of many Chinese gods who bestow happiness on their worshipers.

Fu Hsing, wood sculpture; in the Musée Guimet, Paris

By courtesy of the Musée Guimet, Paris

Some say he is the same as Fu Shen (*q.v.*), the spirit of happiness. If so, Fu Hsing was a historical personage, probably a 6th-century mandarin called Yang Ch'eng, who was deified by the local residents of Tao Hsien in Hunan province.

**Fu-hsing-chen** (China): see Ssu-mao.

**Fu-k'ang-an**, Pinyin FUKANGAN (d. June 1796, China), famous military commander of the Ch'ing dynasty (1644–1911/12).

A member of the Manchu forces of Manchuria who had established the Ch'ing dynasty, Fu-k'ang-an inherited a minor post in the government. After distinguishing himself in battle, he was made military governor of Manchuria (1777). Between 1780 and 1795 he served several terms as governor-general in different Chinese provinces. A corrupt official, he is said to have greatly enriched himself in his various positions.

In combat, however, he was undefeated. He suppressed rebellions in the western Chinese provinces of Szechwan and Kansu, pacified the recently occupied island of Taiwan, and finally led a Chinese expedition into Tibet. There, on unfamiliar territory, 3,000 miles from his source of supplies in the Chinese capital at Peking, he defeated an army of Gurkha

warriors and drove them 1,000 miles (1,600 km) across one of the highest plateaus of the world, back into their homeland in Nepal, which became a Chinese tributary state. For his services, Fu-k'ang-an was made a prince of the fourth degree, the first Manchu outside the Imperial family to receive that rank.

**fu-ping**, Pinyin FUBING, peasant "militia" system established in China around the 6th century AD. The *fu-ping* was first begun by the short-lived Western Wei (535–556/557) and Northern Chou (557–581) dynasties in North China in an effort to prevent incursions by the nomadic tribes of Central Asia. Groups of peasants were given military training and organized into armed companies in which they were required to participate in times of emergency. The T'ang dynasty (618–907) took over this system and made it part of the tax services required of all able-bodied peasants. The system began to collapse toward the middle of the T'ang dynasty. Although it was never formally reinstated, the peasant militia system was frequently attempted by local gentry and officials as a way of pacifying the countryside in times of unrest. This was especially true in the latter part of the Ch'ing dynasty (1644–1911/12), when the deterioration of the regular Imperial forces left the militia system as the only method for the government to control the increasing number of local rebellions.

**Fu Shen**, Pinyin FU SHEN, a Chinese god of happiness, the deification of a 6th-century mandarin. As a generic title, the name Fu Shen denotes the beneficent gods of Chinese mythology.

Yang Ch'eng (or Yang Hsi-chi), who served the Liang Wu Ti emperor (reigned AD 502–549) as a criminal judge in Hunan Province, was deeply disturbed that the ruler was destroying the normal family life of dwarfs by pressing them into service as personal servants and court entertainers. Yang admonished the emperor, pointing out that these unfortunate people were subjects, not slaves. The emperor thereupon called a halt to the practice.

Grateful for Yang's solicitous intercession, the dwarfs set up images of their benefactor and offered sacrifice. The cult of Yang as god of happiness gradually spread throughout China. *Compare* Fu Hsing.

**Fu-Shou-Lu**, Pinyin FUSHOULU, in Chinese mythology, a collective term for the three so-called stellar gods, taken from their names: Fu Hsing, Shou Hsing, and Lu Hsing (*qq. v.*).

**Fu-shun**, Pinyin FUSHUN, city in central Liaoning *sheng* (province), northeastern China. It is situated some 25 miles (40 km) east of Shen-yang (Mukden) on the Hun River. In earlier times this area was on the frontier of Chinese settlement. It was the site of a customs station under the T'ang dynasty (618–907) in the 8th century, and again under the Ming dynasty (1368–1644), when it received the name Fu-shun. It was not until 1902 that settlement in the area became legal for Chinese immigrants; the community then became the seat of a civil county administration.

Its modern development depended on the exploitation of huge nearby bituminous coal reserves beginning in 1905, when the Russian Far Eastern Forestry Company began mining coal at Ch'ien-chin-sai. In 1908 the mines were taken over by the South Manchurian Railway company. By 1930 the mines' output amounted to 75 percent of the total coal production of Manchuria. The coal deposits are enormous. The high-quality coal is suitable for coking and is mined mostly by open-cut methods. After World War II the mines were in damaged condition and production fell off. By 1955, however, they had been reequipped, and normal production resumed. By the mid-1970s the mines' output had declined somewhat as extraction became increasingly diffi-

cult and greater use was made of underground mining techniques.

The coal deposits are covered by a thick layer of oil-bearing shale. Oil was distilled from this shale on an industrial scale from 1930 onward. The output of chemical by-products of coal and of synthetic petroleum from shale remains important, making Fu-shun an important source of fertilizers and industrial chemicals.

In the late 1950s a large iron and steel plant was constructed in Fu-shun to produce pig iron, ingot steel, and finished steel products. A heavy machinery industry was also established. Fu-shun is also a centre of the aluminum industry, which was founded in the late 1930s to serve the Japanese aircraft industry. The Manchurian Light Metals Company established a large plant at Fu-shun in 1938 and a second one in 1941. This industry has been revived and much expanded since 1949. Other Fu-shun industries include the manufacture of rubber, mining equipment, and cement. The city is connected by rail with Shen-yang and T'ung-hua (in Kirin). Pop. (1999 est.) 1,271,113.

**Fu xian** (China): *see* Fu-hsien.

**Fu Xing** (Chinese mythology): *see* Fu Hsing.

**Fu'ad I**, original name AHMED FUAD PASHA (b. March 26, 1868, Cairo—d. April 28, 1936, Egypt), the first king of Egypt (1922–36) following its independence from Great Britain.

After serving in a number of administrative posts, Fu'ad became sultan of Egypt in 1917, at which time Egypt was still a British protectorate. In 1919 Britain indicated a willingness to negotiate a treaty that would give Egypt more independence. Most Egyptians welcomed this prospect, but they differed over who would formulate and present Egyptian demands to the British. The sultan had strong popular support and was determined to be the leading influence in the direction of governmental affairs; but a strong nationalist movement had emerged—the Wafd party—under the leadership of Sa'd Zaghlul. Zaghlul saw himself as the proper person to lead the negotiations with the British.

A stalemate between the supporters of Fu'ad and Zaghlul resulted in the collapse of Anglo-Egyptian talks. Britain responded in 1922 with a unilateral declaration of Egyptian independence, subject to strong British influence in Egyptian affairs. Accordingly, Fu'ad assumed the title of king in 1922. Dissatisfied with the British unilateral declaration, Fu'ad struggled unsuccessfully throughout his reign to secure a bilateral treaty of independence that would be acceptable to the British and the Egyptians.

In 1923 Fu'ad promulgated a constitution at a time when Zaghlul was in exile. When Zaghlul and other exiles returned, however, the king was confronted with an enormously popular Wafd, which used institutions created by the constitution to strengthen its opposition. The Wafd won commanding majorities in national elections held in 1923, 1925, and 1929, but Fu'ad usually managed to form his governments with non-Wafdist ministers who were amenable to his influence. Socially and religiously, Fu'ad aligned himself with the outlook and interests of al-Azhar, Cairo's great institution of Muslim learning, which won him important popular support. In 1930 he made a determined attempt to stabilize his political position: he dissolved the Parliament, revoked the old constitution, and promulgated both a new constitution and a new electoral law. The 1931 elections yielded a cooperative, non-Wafdist parliament, and domestic political tranquillity prevailed until 1935, when, under strong nationalist pressure, Fu'ad restored the original 1923 constitution.

**Fuad Paşa, Mehmed** (b. 1815, Constantinople [now Istanbul]—d. Feb. 12, 1869, Nice, Fr.), Turkish statesman of the mid-19th cen-

tury and one of the chief architects of the Tanzimat (Reorganization), aimed at the modernization and westernization of the Ottoman Empire.

The son of a well-known Turkish poet, Fuad Paşa was trained in medicine, but his knowledge of French allowed him to enter the diplomatic service, where he became the first secretary of the Turkish Embassy in London (1840). After holding several diplomatic posts, he served as minister of foreign affairs under Ali Paşa (1852–53) and again in 1855–56.

A confirmed westernizer, Fuad Paşa served on the Commission of Education, which recommended a complete reform of the school system. He assumed the presidency of the Tanzimat Council in 1857. After the accession of Sultan Abdülaziz (1861), Fuad Paşa became grand vizier and foreign minister, and, although dismissed in 1862, he returned to office in 1863. He held the grand viziership until 1867.

A scholar as well as a statesman, he collaborated with the historian Ahmed Cevdet in writing *Kavaid-i Osmaniye* (1851; "The Rules of Ottoman Turkish"), the first Turkish work on Turkish grammar published in the empire and a milestone in the reform of the language.

**fubing** (China): *see* fu-ping.

**Fuchs, (Emil) Klaus (Julius)** (b. Dec. 29, 1911, Rüsselsheim, Ger.—d. Jan. 28, 1988, East Germany), German-born physicist and spy who was arrested and convicted (1950) for giving vital American and British atomic-research secrets to the Soviet Union.

Fuchs studied physics and mathematics at the universities of Leipzig and Kiel and joined the German Communist Party in 1930. He was forced to flee Germany after the Nazis came to power in 1933, and he ended up in Great Britain, where he studied at the University of Edinburgh and received a doctorate there. He was briefly interned as a German at the start of World War II but was soon released in order to do research on the atomic bomb at the University of Birmingham. In 1942 he became a British citizen. When Fuchs realized the importance of the research he was engaged upon, he began passing scientific secrets on to the Soviet Union. In 1943 he was sent to the United States to work on the atomic bomb project at Los Alamos, where he acquired a thorough knowledge of the theory and design of the bomb and passed his knowledge on to the Soviets. His espionage is credited with saving the Soviets at least one year's work in their own program to develop the atomic bomb.

After the war he returned to England, where he became head of the physics department of the British nuclear research centre at Harwell. His espionage activities were finally detected and he was arrested in 1950, upon which he admitted passing information to the Soviet Union since 1943. He was sentenced to 14 years in prison. After his release in 1959 for good behaviour, he went to East Germany, where he was granted citizenship and was appointed deputy director of the Central Institute for Nuclear Research, Rossendorf (near Dresden). He remained a committed Communist and received many honours from the East German Communist Party and the scientific establishment there.

**Fuchs, Leonhard** (b. Jan. 17, 1501, Wemding, Bavaria [Germany]—d. May 10, 1566, Tübingen, Württemberg [Germany]), German botanist and physician whose botanical work *Historia Stirpium* (1542) is a landmark in the development of natural history because of its organized presentation, the accuracy of its drawings and descriptions of plants, and its glossary.

Fuchs obtained a humanistic education under Catholic guidance but later adhered to Protestantism. He studied medicine and became a professor at Tübingen. He was most interested in the medicinal properties of plants, and his

Winter cherry (*Physalis alkekengi*), coloured woodcut from *De historia stirpium* by Leonhard Fuchs, 1542

By courtesy of the British Library Board

book was intended primarily as a guide for plant collection. Well acquainted with the Greek and Latin classics, and an excellent observer, he gave precise descriptions, and his beautiful woodcuts of plants established the tradition of representing plants by means of accurate illustrations. He presented the plants in alphabetical order; for each one he gave an account of its form and habitat, the best season for collection, and what he called its temperament and powers. Only under the subject of powers did he refer to ancient authorities. His name is commemorated by a genus of flowering plants (*Fuchsia*; see photograph).

**Fuchs, Lukas:** see Foss, Lukas.

**Fuchs, Sir Vivian Ernest** (b. Feb. 11, 1908, Freshwater, Isle of Wight, Eng.—d. Nov. 11, 1999, Cambridge, Cambridgeshire), English geologist and explorer who led the historic British Commonwealth Trans-Antarctic Expedition in 1957–58. Fuchs's 12-man party completed the first land journey across Antarctica in 99 days despite severe hardships, travelling 2,500 miles (4,000 kilometres) from the Filchner Ice Shelf to McMurdo Sound. The findings of the expedition confirmed earlier theories that a single continent exists beneath the Antarctic polar ice sheet. For his leadership on the expedition and contributions to Antarctic exploration, Fuchs was knighted in 1958.

In 1929 and 1930–31 Fuchs participated in expeditions to East Greenland and the East African lakes, respectively, serving as a geologist. In 1933–34 he led the Lake Rudolf–Rift Valley Expedition that surveyed 40,000 square miles (104,500 square kilometres) of the Ethiopia–Kenya region. Fuchs's thesis on the tectonics (*i.e.*, crustal structure) of the Rift Valley earned him a Ph.D. in geology from Cambridge University in 1935. Selected to head the Falkland Islands Dependencies Surveys in 1947, he became interested in Antarctica. Fuchs and Sir Edmund Hillary co-authored the book *The Crossing of Antarctica* (1958).

**Füchsel, Georg Christian** (b. Feb. 14, 1722, Ilmenau, Thuringia, Holy Roman Empire—d. June 20, 1773, Rudolstadt, Thuringia), German geologist, a pioneer in the development of stratigraphy, the study of rock strata.

Füchsel began medical practice in 1756 and the following year was appointed to organize the natural science collections of Friedrich Carl, later prince of the German principality of Schwarzburg-Rudolstadt, where Füchsel became court physician (1767) and librarian (1770). The originator of the idea of stratigraphic formations, he was one of the first actually to make recorded measurements of sections of stratified rock. He also made the first geological map of Germany and adjacent areas.

**Fuchsia**, genus of about 100 species of flowering shrubs and trees, in the evening primrose family (Onagraceae), native to the cooler regions of Central and South America and to New Zealand and Tahiti. Several species are grown in gardens as bedding plants, small shrubs, or miniature treelike specimens; others are grown as pot plants or in hanging baskets for indoor or greenhouse cultivation. They are valued for their showy pendulous flowers, tubular to bell-shaped, in shades of red and purple to white. The hanging growth habit and flared shape of the flower gave rise to the popular name ladies' eardrop.

The colour fuchsia—a deep reddish-purple,

*Fuchsia*

Malak—Annan Photo Features

seen in the flowers of some species—is named for the genus. The genus in turn is named for Leonard Fuchs, a 16th-century botanist and physician.

Suitable for growth in hanging baskets are the prostrate *Fuchsia procumbens* and the dwarf and trailing forms of the common hybrids (*F. × hybrida*, probably derived from *F. fulgens* and *F. magellanica*). The garden fuchsias, probably derived from *F. fulgens*, *F. magellanica*, and *F. corymbiflora*, are widely grown in shady borders. One tree fuchsia (*F. excorticata*), from New Zealand, up to 15 metres (50 feet) high, has dull-red waxy flowers and papery bark; a Mexican tree fuchsia, *F. arborescens*, up to 10 m, has lilac and purple flower clusters.

**Fuchū**, city, Tokyo Metropolis (*to*), Honshu, Japan, on the Tama-gawa (Tama River). The capital of Musashi Province about the 7th century AD, it flourished as a post town and regional commercial and administrative centre. Fuchū declined when it was bypassed by the railway between Tokyo and Tachikawa (1889), but it revived with the arrival of two other railways in the late 1920s and the construction of the Tokyo Race Course in 1933.

During World War II, army installations were converted into metal-producing plants; heavy industrialization has since steadily continued. Fuchū houses the headquarters of Japan's Air Self-Defense Force and serves as a residential suburb of the Tokyo–Yokohama Metropolitan Area. Its population almost doubled between 1960 and 1970; the rate of population growth slowed after 1970. Pop. (1995 prelim.) 216,202.

**Fucino Basin**, Italian CONCA DEL FUCINO, formerly LAGO FUCINO, or LAGO DI CELANO, Latin LACUS FUCINUS, former lake bed in L'Aquila province, Abruzzi region, central Italy, just east of Avezzano. The lake was once 37 mi (59 km) in circumference and about 100 ft (30 m) deep, although its level was subject to great variations because of the lack of an outlet. As early as AD 52 the emperor Claudius had a tunnel constructed, 3½ mi (5½ km) long, as an outlet to the Liri (Liris) River. The tunnel, still evident but no longer in use, fell into disrepair and various attempts to reopen it from 1240 onward were unsuccessful; by 1852 the lake had risen 30 ft above its former level. In 1854–75 Prince Alessandro Torlonia, a Roman banker, aided by French and Swiss engineers, drained the lake, becoming proprietor of the site in return, hence the name *conca* ("basin"). The reclaimed fertile land, belonging to the Torlonia family, was expropriated and divided into numerous small farms (each about 2½ ac [1 ha]) by the Italian Land Reform Acts in 1952–53. Cereals, potatoes, sugar beets, grapes, and fruit are grown. Italy's principal satellite tracking station is located in the Fucino Basin.

**Fucus**, also called ROCKWEED, genus of brown algae, common on rocky seacoasts and in salt marshes of northern temperate regions. Adaptations to its environment include bladderlike floats (pneumatocysts), disk-shaped holdfasts for clinging to rocks, and mucilage-covered blades for resisting desiccation and temperature changes. The plant is between 25 and 30 centimetres (9.8 to 11.8 inches) in total length; growth of the thallus is localized and occurs at the tip of forked shoots that arise from the holdfasts. The male and female reproductive organs may occur on the same or separate organisms; some species produce eggs and sperm all year long. *Fucus* is a perennial alga with a lifespan of up to four years. In Roman times it was the source of a brown facial cosmetic. Today *Fucus* species, along with

Rockweed, or common bladderwrack (*Fucus vesiculosus*)

Douglas P. Wilson

kelp (*q.v.*), are an important source of alginates—colloidal extracts with many industrial uses similar to those of agar.

**fudge**, creamy candy made with butter, sugar, milk, and usually chocolate, cooked together and beaten to a soft, smooth texture. Fudge may be thought of as having a consistency harder than that of fondant (*q.v.*) and softer than that of hard chocolate. According to most recipes, the ingredients of fudge are cooked to what is termed in kitchen parlance the soft

ball stage, that point between 234° and 240° F (112° and 115° C) at which a small ball of the candy dropped in ice water neither disintegrates nor flattens when picked up with the fingers. Butter and vanilla are added as the candy cools, then the mass is beaten until creamy, poured into a pan, and cut into squares. Often sour cream is substituted for milk and butter, and nut meats or raisins may be stirred into the fudge.

Although chocolate is the usual base for the candy, fudges are often made with marshmallow cream, peanut butter, vanilla, maple, or butterscotch. Various flavoured fudges are used as cake icings and ice cream toppings.

**Fuehrer** (German title): see Führer.

**fuel cell**, any of a class of devices that convert the chemical energy of a fuel directly into electricity by electrochemical reactions. A fuel cell is much more efficient than most other types of energy converters.

A brief treatment of fuel cells follows. For full treatment, see MACROPAEDIA: Energy Conversion: *Fuel cells*.

A fuel cell resembles a primary cell—i.e., a voltaic battery. In both types of devices, chemical reactions occur so that electrons are released on one electrode and caused to flow through an external circuit to a second electrode. There is, however, one major difference between batteries and fuel cells. In the former, the active ingredients are incorporated within the electrodes and are chemically altered during the reaction, becoming depleted with use. In fuel cells, a gas or liquid fuel is supplied continuously to one electrode and oxygen or air to the other from an external source. Because of this feature, fuel cells are able to produce electrical energy for a substantially longer period of time than can batteries (see also battery).

During the late 1830s, William R. Grove of Great Britain built what is often considered the first fuel cell. His device produced electric current from hydrogen and oxygen reacting on platinum electrodes. Throughout the balance of the century there was a continuing effort to produce electricity from direct electrochemical oxidation of a conventional fuel such as coal or from the carbon monoxide and hydrogen derivable from coal. Molten salts as well as aqueous solutions were tried as electrolytes. Although all the basic principles of operation were recognized and considerable ingenuity applied to development, none of this early work led to devices able to compete with electric generators driven by steam or water power. Reactions were inefficient, rates were too slow, and cell life too short.

After World War II there was a significant increase in interest in the development of practical fuel cells and batteries capable of large-scale electric-power generation. The promise of improvements resulting from new technology, the demanding requirements of military and space-vehicle programs, and the concentrated effort to reduce atmospheric pollution from power plants and internal-combustion engines accelerated fuel-cell research and development by the early 1960s. Many kinds of fuel cells were shown to be operable, and a number of them were refined into practical systems. Hydrogen, methyl alcohol, hydrazine, and some of the simpler hydrocarbons have been used directly as fuels. Air and oxygen have been employed as oxidants. A variety of electrolytes have been utilized: concentrated alkaline or acid solutions usually at temperatures below 150° C (300° F), and molten carbonates and other salts at temperatures of several hundred degrees Celsius. Certain cells have used ionically conducting modified zirconium oxide as a solid electrolyte at temperatures near 1,000° C (1,830° F). In most modern fuel cells, the electrodes consist of porous metal or carbon and

at lower temperatures include catalysts to increase reaction rates to reasonable levels.

Some fuel-cell types have been built into systems incorporating a means for storage and controlled supply of fuel and oxidant and for the removal of heat and reaction products. Two such systems, using liquid hydrogen and oxygen, have served as a primary electric-power source for U.S. manned spacecraft. For possible future space flights of long duration (e.g., missions to other planets), solar or nuclear generators are considered more suitable, though regenerative fuel cells (i.e., those whose operation can be reversed to regenerate hydrogen and oxygen) may be used to supplement these devices. Hydrogen-oxygen fuel cells also have been used to power forklift trucks and small automotive vehicles on an experimental basis. Various exploratory attempts have been made to introduce fuel cells into commercial use, but so far none have been particularly successful. Fuel cells that operate on methanol, however, have been employed on a limited scale to power television repeater stations and navigation beacons.

**fuel injection**, in an internal-combustion engine, introduction of fuel into the cylinders by means of a pump rather than by the suction created by the movement of the pistons. On diesel engines, which have no spark plugs, the heat created by compressing air in the cylinders ignites the fuel, which has been pumped as a spray into the heated air. In engines with spark ignition, fuel-injection pumps are often used instead of conventional carburetors. Fuel injection distributes the fuel more evenly to the individual cylinders than does a carburetor system, so that more power can be developed and undesirable emissions are reduced. In engines with continuous combustion, such as gas turbines and liquid-fueled rockets, which have no pistons to create a pumping action, fuel-injection systems are necessary.

**fuel oil**, also called FURNACE OIL, fuel consisting mainly of residues from crude-oil distillation. It is used primarily for steam boilers in power plants, on board ship, and in industrial plants. Commercial fuel oils usually are blended with other petroleum fractions to produce the desired viscosity and flash point. Flash point is usually higher than that of kerosene. The term fuel oil ordinarily does not include such fuels as kerosene.

**Fuentes, Carlos** (b. Nov. 11, 1928, Mexico City), Mexican novelist, short-story writer, playwright, critic, and diplomat whose experimental novels won him an international literary reputation.

The son of a career diplomat, Fuentes traveled extensively with his family. At age four he learned English in Washington, D.C. He studied law at the University of Mexico, Mexico City, and later attended the Institute of Advanced International Studies in Geneva.

Fuentes was a member of the Mexican delegation to the International Labour Organization (ILO) in Geneva (1950–52), was cultural officer of the ministry (1957–59), and was ambassador to France (1975–77). He also co-founded and edited several periodicals, including *Revista Mexicana de Literatura* (1954–58; "Mexican Review of Literature").

Early in the 1950s, Fuentes became a communist, but he left the party in 1962 on intellectual grounds while remaining an avowed Marxist. His first collection of stories, *Los días enmascarados* (1954, 2nd ed. 1966; "The Masked Days"), recreates the past realistically and fantastically. His first novel, *La región más transparente* (1958; *Where the Air Is*

Carlos Fuentes

© Vittorio Rastelli—Corbis

*Clear*), which treated the theme of national identity and bitterly indicted Mexican society, won him national prestige. The work was marked by cinematographic techniques, flashbacks, and interior monologues, and showed influences from many non-Spanish literatures. After this, Fuentes spent most of his time writing but continued to travel widely.

The novel *Las buenas conciencias* (1959; good *Good Conscience*) emphasized the moral compromises that mark the transition from a rural economy to a complex, middle-class urban one. *La muerte de Artemio Cruz* (1962; *The Death of Artemio Cruz*), which presents the last hours of a wealthy survivor of the Mexican Revolution, was translated into several European languages and established Fuentes as a major international novelist.

After *Artemio Cruz* came a succession of novels. *Cambio de piel* (1967; *A Change of Skin*) defines existentially a collective Mexican consciousness by reinterpreting the country's myths. *Terra nostra* (1975; "Our Land," Eng. trans. *Terra nostra*) explores the cultural substrata of New and Old worlds, using Jungian archetypal symbolism. In 1995 Fuentes published *La frontera de cristal* (*The Crystal Frontier*), a tale of nine lives affected by a powerful, unscrupulous man. Among his other novels are *Gringo viejo* (1985; *The Old Gringo*; filmed in 1989) and *Cristóbal nonato* (1987; "Christopher Unborn").

Fuentes published several collections of stories, including *Constancia, y otras novelas para vírgenes* (1989; *Constancia and Other Stories for Virgins*) and *El naranja o los círculos del tiempo* (1993; "The Orange Tree or the Circles of Time," Eng. trans. *The Orange Tree*). English translations of 11 of his stories appear in *Burnt Water* (1980). He also wrote several plays.

Among Fuentes's nonfiction works are *La nueva novela hispanoamericana* (1969; "The New Hispano-American Novel"), his chief work of literary criticism; *Cervantes o la crítica de la lectura* (1976; "Cervantes or the Critique of Reading," Eng. trans. *Don Quixote, or the Critique of Reading*), an homage to the great Spanish writer; and his book-length essay on Hispanic cultures, *El espejo enterrado* (1992; *Buried Mirror*).

**BIBLIOGRAPHY.** Works of criticism on Carlos Fuentes include Maarten Van Delden, *Carlos Fuentes, Mexico, and Modernity* (1998); Chalene Helmut, *The Postmodern Fuentes* (1997); Raymond Leslie Williams, *The Writings of Carlos Fuentes* (1996); Wendy B. Faris, *Carlos Fuentes* (1983); and Daniel de Guzmán, *Carlos Fuentes* (1972).

**fuero** (from Latin *forum*, "marketplace"), in medieval Spain, a municipal franchise conferred on a community by the crown or by a noble or bishop. It granted legal incor-

poration, confirmed local customs or privileges, and might include rights to taxation or self-government. The word is also applied to a code—the Liber Judiciorum of the Visigoths—known in the Middle Ages as the Fuero Juzgo. Because of the great number and variety of the medieval *fueros municipales* and the tenacity with which the municipalities clung to privileges granted under them, the *fueros* played an important part in the political, administrative, and judicial history of Spain.

During the Christian reconquest of Spain from the Muslims (11th–15th century), the various Christian kings frequently granted special privileges and exemptions in order to provide incentives for settlers in newly conquered towns and to modify legal and administrative practice in a way that was appropriate for frontier towns dependent on the crown but far from the centre of government. Nearly 800 such *fueros* were granted between the 11th and 14th centuries.

The oldest in the west is the *Fuero de León* (c. 1020), which contains laws applicable to the kingdom in general and to the city of León in particular. The oldest Aragonese *fuero* was believed to be that of Sorbarbe (late 11th or early 12th century), though some modern scholars treat it as suspect. The Navarrese *fueros* were modeled on those of Aragon.

A feature of later *fueros* was that some types were preferred or adopted in toto by whole regions. The earliest *fueros* could be short, but by the end of the 12th century they tended to be complicated documents. That of Cuenca (c. 1189) is the most elaborate of the Castilian *fueros*.

**Fuero Juzgo** (Visigothic law code): see Liber Judiciorum.

**Fuerte Olimpo**, city, northern Paraguay. Lying across the Paraguay River from Brazil, the city dates from 1792 when a fort called Borbón was established on the present site. Fuerte Olimpo, which lies in the thinly populated Chaco Boreal, is the area's principal port and serves as a trade centre. Livestock raising is the principal economic activity in the region; tanneries and tileworks are located in Fuerte Olimpo. The city is accessible by a branch road running north and east from the trans-Chaco highway, but most travel south to Asunción is by river. Pop. (1992 prelim.) 1,532.

**Fuerte River**, Spanish RÍO FUERTE, river in northwestern Mexico, formed in Chihuahua state by the junction of the Verde and Urique rivers, and descending generally southwestward through Sinaloa state from the Sierra Madre Occidental to the Gulf of California, 27 miles (43 km) west of Los Mochis at Lechuguilla Island. Waters of the river, controlled in part by the Hidalgo Dam, are used for extensive irrigation projects on the gulf lowlands around Los Mochis. The Fuerte is approximately 175 miles long (350 miles including the Verde River).

**Fuertes, Dolores Adios** (U.S. actress): see Menken, Adah Isaacs.

**Fuerteventura Island**, Spanish ISLA DE FUERTEVENTURA, island, one of the eastern Canary Islands, Las Palmas provincia, Canary Islands *comunidad autónoma* ("autonomous community"), Spain. It lies in the North Atlantic, 65 miles (105 km) west of Cape Juby, Morocco. This volcanic island, second largest of the Canaries, measures 60 miles in length and has an area of 668 square miles (1,730 square km). It lies southwest of Lanzarote (island) across Bocaína Strait. The island, rising to 2,648 feet (807 m) at Jandía Peninsula (southwest), has eroded beaches. It has a warm and dry climate with scanty rainfall occurring mostly in winter. Puerto del Rosario and Gran

Eroded beaches on Fuerteventura Island  
Ernst A. Weber—Photo Researchers

Tarajal, both on the east shore, are the largest settlements on the island. There is regular airline service to Gran Canaria and Tenerife. Pop. (1991) 36,908.

**fugacity**, a measure of the tendency of a component of a liquid mixture to escape, or vaporize, from the mixture. The composition of the vapour form of the mixture, above the liquid, is not the same as that of the liquid mixture; it is richer in the molecules of that component that has a greater tendency to escape from the liquid phase. The fugacity of a component in a mixture is essentially the pressure that it exerts in the vapour phase when in equilibrium with the liquid mixture.

**Fugard, Athol**, in full ATHOL HAROLD LANIGAN FUGARD (b. June 11, 1932, Middleburg, S.Af.), South African dramatist, actor, and director who, despite South African drama's particular vulnerability to censorship, sustained a theatre group in Port Elizabeth that produced plays defiantly indicting the apartheid policy.

Fugard's earliest plays were *No-Good Friday* (1958) and *Nongogo* (1957), but it was *The Blood Knot* (1961), produced for stage and television in both London and New York City, that established his international reputation. *The Blood Knot*, dealing with brothers who fall on opposite sides of the racial colour line, was the first in a sequence of plays called "The Family Trilogy." It continued with *Hello and Goodbye* (1965) and *Boesman and Lena* (1969) and was later published under the title *Three Port Elizabeth Plays* (1974). *Boesman and Lena*, later filmed with Fugard as Boesman, played to a wider audience than any previous South African play. These penetrating analyses of the South African situation are powerful and essentially pessimistic.

Fugard's willingness to sacrifice character to symbolism caused some critics to question his commitment. Provoked by such criticism, Fugard began to question the nature of his art and his emulation of European dramatists. He began a more imagist approach to drama, not using any prior script but merely giving actors what he called "a mandate" to work around "a cluster of images." From this technique derived the imaginative if shapeless drama of *Orestes* (1971) and the documentary expressiveness of *Sizwe Bansi Is Dead* and *The Island* (both 1972 and both cowritten with actors John Kani and Winston Ntshona) and *Statements After an Arrest Under the Immorality Act* (1974).

A much more traditionally structured play, *Dimetos* (1975), was performed at the Edinburgh Festival. *A Lesson from Aloys* (1978), the semiautobiographical *Master Harold... & the Boys* (1982), *The Road to Mecca* (1984), and *My Children! My Africa!* (1989) were performed to much acclaim in London and New York City. Fugard's films include *The Guest*

(1977) and *Marigolds in August* (1979). *Tsotsi* (1980) is Fugard's only novel.

**Fugen-dake** (Japan): see Unzen-dake.

**Fugger FAMILY**, German mercantile and banking dynasty that dominated European business during the 15th and 16th centuries, developed capitalistic economic concepts, and influenced continental politics.

*The founding fathers.* Hans Fugger, a weaver born in the village of Graben in Swabia, established the family in Augsburg in 1367. By twice marrying the daughters of masters of the weavers' guild, the industrious Fugger acquired civic rights and the freedom of the company. He also became a member of the guild's committee of 12 and of the city's great council and conducted a successful textile trade. After his death in 1408, his sons Andreas and Jakob I, both of whom had learned the goldsmith's trade, jointly carried on the family business until they dissolved their partnership in 1454. Although Andreas, the more enterprising of the two, and his descendants quickly attained great wealth, they went bankrupt in 1499, as a result of an overextension of business activity and the loss of a lawsuit. These Fugger vom Reh (Fuggers of the Doe, from their coat of arms) spread over southern, central, and eastern Germany; as late as 1944, there were Fugger (descendants of the Fuggers) residing in Warsaw.

In 1441 Jakob had married the daughter of a mint master who went bankrupt three years later. Warned by this event, Jakob proceeded carefully in his business; yet by perseverance and industry he succeeded in substantially increasing his profits, and in 1463 he was made a member of the more highly respected merchants' guild. After his death in 1469, two of his seven sons, Ulrich and Georg, profitably expanded the firm's international trade. In 1473 they were granted a coat of arms with a lily, causing this branch of the family to be called Fugger von der Lilie. With the help of their brother Markus in Rome, they handled remittances to the papal court of monies for the sale of indulgences and the procuring of church benefices. From 1508 to 1515 they leased the Roman mint.

Jakob II Fugger the Rich (right), and his chief accountant, Matthäus Schwarz, miniature, 1519; in the Herzog Anton Ulrich-Museum, Braunschweig, Ger.

By courtesy of the Herzog Anton Ulrich-Museum, Braunschweig

Ulrich and Georg established an agency of their own in the German merchants' building in Venice, where their youngest brother, Jakob II the Rich, who had originally been destined for an ecclesiastical career, studied modern

bookkeeping from 1478 on. Taking charge of the Fugger agency in Innsbruck in 1485, he showed sound business acumen in making the firm a partner in the Tirolean mines by granting permanent loans, secured by deliveries of copper and silver, to Archduke Sigismund and King (later Emperor) Maximilian. The large profits realized from this venture encouraged the Fuggers to participate also in mining operations in Silesia. There Jakob, a shrewd and sober yet enterprising merchant, met a mining expert with whom he leased the copper mines in Neusohl (modern Banská Bystrica, Slovakia) in 1495, eventually building them up into the greatest mining centre of the time.

In 1494 the Fuggers established their first public company with a capital of 54,385 guilders, a sum that was to be doubled two years later when Jakob persuaded the Prince Bishop of Brixen to join the company as a silent partner. Jakob's aim was to establish a copper monopoly by opening foundries in Hofenkirchen and Fuggerau (named for the family, in Carinthia, now Austria) and by expanding the sales organization in Europe, especially the Antwerp agency. True to his motto, "I want to gain while I can," Jakob, unhappily married since 1498 and without an heir, engaged in all manner of commerce, including the lucrative spice trade. The taciturn and hard-driving merchant had long ago assumed the direction of the firm. The death of his chief creditor, the Prince Bishop of Brixen, whose inheritance was claimed by the Pope, brought about a serious crisis that Jakob managed to solve through shrewd negotiations. Prudently, he divided the company's assets equally into cash holdings, production plants and merchandise, landed properties, and precious stones. In 1504 he thus secretly purchased from the city of Basel a portion of the captured crown jewels of Charles the Bold, duke of Burgundy. Laying the foundation for the family's widely distributed landholdings, he acquired the countships of Kirchberg and Weissenhorn from Maximilian I in 1507. In 1514, the emperor made him a count.

The chief financial supporter of Maximilian I's policies since 1490, Fugger was identified with these policies for better or for worse, even though he refused to support Maximilian's bid for the papacy. His greatest achievement was the financing of the election of Charles V, Maximilian's successor, as emperor. Of the total election expenses of 852,000 guilders, Jakob Fugger alone raised almost 544,000 in order to eliminate Francis I of France. By skillful negotiations he arranged to have this debt repaid out of the Maestrazgo—the lease of the revenues paid to the Spanish crown by the three great knightly orders. A part of the sum came from the mercury mines of Almadén and the silver mines of Guadalcanal. In 1516 he also made an ally of King Henry VIII of England by granting him various loans.

At the height of his power Jakob Fugger was sharply criticized by his contemporaries, especially by the German humanist and reformer Ulrich von Hutten and by Martin Luther, for his stand on interest charges (the Fuggers were among the merchant dynasties that urged the Pope to rescind or amend the medieval prohibition on the levying of interest) and the sale of indulgences and benefices, as well as for his loan policies. The imperial fiscal and governmental authorities in Nürnberg brought action against him and other merchants to halt their monopolistic tendencies. Fugger's position was furthermore threatened by social unrest among the miners in the Tirol and at Neusohl in Hungary, by attempts of the Hungarian nobles to nationalize his mines, and by the Peasants' Revolt. At the Augsburg headquarters he was threatened by an uprising of artisans. Fugger mastered these crises through sheer tenacity and fixity of purpose. Albrecht Dürer has immortalized the severe, taciturn countenance of the master merchant. As head

of the company, Fugger, who was himself a man of few wants, created monuments to his time that have survived for centuries—in the Fugger buildings and the splendid memorial chapel and above all in the Fuggerei, the world's oldest social settlement, which he endowed as a peaceful haven for his impoverished old servants and fellow citizens. In his last years, seeing his work and his church threatened by the Reformation, he fought the new movement.

*Decline of the house.* At his death in 1525, Jakob the Rich bequeathed to his nephew Anton Fugger, who had been destined for the succession since 1517, company assets totaling 2,032,652 guilders. The new chief, an ambitious and talented businessman, guided the company with a firm hand. In 1527 he married Anna Rehlinger, a patrician's daughter who bore him four sons. Most of Anton's time was taken up with the securing of permanent loans for the emperors Charles V and Ferdinand I and for King Philip II of Spain. In accordance with his credo that money is the sinews of war—*pecunia nervus bellorum*—Fugger, a strict Roman Catholic, granted the emperor credits that proved to be decisive in the struggle against the Protestants and particularly in the war against the Schmalkaldic League of Protestant princes and cities. While large sales of fustian cloth to England and loans extended to its kings proved to be profitable, the formerly rich yield of the Tirolean and Hungarian mines decreased until Anton gave up Neusohl altogether in 1547. With dogged resolution but little success, he tried to make up for these losses by establishing new trade ties with Peru and Chile and by engaging in mining ventures in Sweden and Norway, as well as in the slave trade from Africa to America. He was, however, more successful in the spice trade and the importation of Hungarian cattle. National resentments in Spain forced him to renounce the Maestrazgo lease after 1542 and to give up the silver mines of Guadalcanal. Nonetheless, Anton Fugger had, by 1546, amassed 5,100,000 guilders—the highest capital in the company's history.

His health weakened in 1540, Anton Fugger reacted more acutely to the shifts in his fortunes; since his sons and nephews showed little interest in business, he even considered dissolving the firm. When that proved impossible, he stubbornly tried to carry on, although he could satisfy the demand for credit only by increased borrowing. An inventory taken after his death in 1560 showed assets of 5,600,000 and liabilities of 5,400,000 guilders (2,900,000 in Spain alone). Anton had, however, safeguarded part of his fortune through the timely purchase of Babenhausen and other landed estates. After the personal bankruptcy of his nephew Hans Jakob Fugger, who had become a partner in 1543 and who eventually became Bavarian chancellor, Anton's oldest son, Markus, carried on the business successfully, if on a reduced scale. During the period 1563–1641 the company, which was not completely dissolved until after the Thirty Years' War, earned some 50,000,000 ducats from the production of mercury at Almadén alone.

While Jakob and Anton Fugger had hardly made use of their title as counts, their descendants, showing little mercantile inclination, acquired a humanistic education at European universities. Marrying within their class, they spent most of their lives on their estates, where they established valuable libraries and built magnificent residences. It is to Jakob and Anton Fugger's land purchases that the three surviving lines of the family (all dating from the mid-16th century)—the counts Fugger-Kirchberg of Oberkirchberg, the prince Fugger-Glött of Kirchheim, and the prince Fugger-Babenhausen of Babenhausen—owe the preservation of a part of the great wealth once held by the family firm.

The Fugger family may be considered a pro-

TOTYPE of the trading company of the early capitalistic era. In overcoming the economic concepts of the Middle Ages, they used methods that have evoked, both in their time and in the present, admiration as well as violent criticism. (F.Br.)

**BIBLIOGRAPHY.** A comprehensive presentation by Götz Freiherr von Pölnitz, *Die Fugger*, 3rd ed. (1970, reissued 1981), offers the best survey of the Fugger family and contains an extensive bibliography. The same author's biographies (in German) *Jakob Fugger*, 2 vol. (1941–51), and *Anton Fugger*, 3 vol. in 5 (1958–86), are instructive sourcebooks based on research in major European archives. Richard Ehrenberg, *Capital & Finance in the Age of the Renaissance: A Study of the Fuggers and Their Connections* (1928, reprinted 1985), is a pioneering study of money and credit circulation in the 16th century. Jacob Strieder, *Jacob Fugger the Rich: Merchant and Banker of Augsburg, 1459–1525* (1931, reprinted 1984), is a biography.

**fuging tune**, a form of hymnody developed by American composers of the so-called First New England school during the period of the American Revolution (1775–83).

A typical fuging tune places the tune in the tenor voice and harmonizes it with block chords. In the next-to-last phrase, called the fuging section or fuge, each of the four voices enters in turn singing the tune or a slightly varied version of it. The last phrase is again chordal. The fuge, although all four parts follow each other in melodic imitation, is not a classical fuge but merely a passage that uses imitative writing.

The term fuging tune is a shortened form of the English phrase "fuging psalm tune," a type of hymn setting popular in England in the 17th and early 18th centuries. Minor features of style—angular melodic writing, rhythmic simplicity and precision, and diatonic harmony (*i.e.* little use of notes foreign to the composition's key)—and the placement of the fuging section in the next-to-last, not the last, line distinguish the American fuging tune from its British parent.

James Lyon's collection *Urania* (1762) contains the first fuging psalm tune published in America. The first fuging tunes appeared in William Billings' *Singing Master's Assistant* of 1778. Other American composers such as Daniel Read, Timothy Swan, Jacob French, and Justin Morgan preferred writing this type of piece until around 1800.

Subsequently, European composers and their works captured the imagination of New England musicians. But the fuging tune, carried to the west and south in various shape-note hymnals (which use a characteristic musical notation), remained popular outside of New England for at least another 50 years.

**Fugitive**, any of a group of young poets and critics formed shortly after World War I at Vanderbilt University in Nashville, Tenn., some of whom later became distinguished men of letters. The group, led by the poet and critic John Crowe Ransom (*q.v.*), devoted itself to the writing and discussion of poetry and published a bimonthly magazine, *The Fugitive* (1922–25), edited by poet Allen Tate (*q.v.*). Other important members of the group were the poet, essayist, and critic Donald Davidson and the novelist and poet Robert Penn Warren. Outstanding selections from the magazine were collected in the *Fugitive Anthology* (1928).

Acutely aware of their Southern heritage, the Fugitives advocated a form of literary regionalism, concentrating largely on the history and customs of the South in their work. Many of the Fugitives went on to become leaders in

the Agrarian movement of the 1930s, which sought to resist the inroads of industrialism by a return to the agricultural economy of the Old South. Their views were published as a symposium in *I'll Take My Stand* (1930).

**Fugitive Slave Acts**, in U.S. history, statutes passed by Congress in 1793 and 1850 (and repealed in 1864) that provided for the seizure and return of runaway slaves who escaped from one state into another or into a federal territory. The 1793 law enforced Article IV, Section 2, of the U.S. Constitution in authorizing any federal district judge or circuit court judge, or any state magistrate, to decide finally and without a jury trial the status of an alleged fugitive slave.

The measure met with strong opposition in the Northern states, some of which enacted personal-liberty laws to hamper the execution of the federal law; these laws provided that fugitives who appealed from an original decision against them were entitled to a jury trial. As early as 1810 individual dissatisfaction with the law of 1793 had taken the form of systematic assistance rendered to black slaves escaping from the South to New England or Canada—via the Underground Railroad (*q.v.*).

The demand from the South for more effective legislation resulted in enactment of a second Fugitive Slave Act in 1850. Under this law fugitives could not testify on their own behalf, nor were they permitted a trial by jury. Heavy penalties were imposed upon federal marshals who refused to enforce the law or from whom a fugitive escaped; penalties were also imposed on individuals who helped slaves to escape. Finally, under the 1850 act, special commissioners were to have concurrent jurisdiction with the U.S. courts in enforcing the law. The severity of the 1850 measure led to abuses and defeated its purpose. The number of Abolitionists increased, the operations of the Underground Railroad became more efficient, and new personal-liberty laws were enacted in many Northern states. These state laws were among the grievances officially referred to by South Carolina in December 1860 as justification for its secession from the Union. Attempts to carry into effect the law of 1850 aroused much bitterness and probably had as much to do with inciting sectional hostility as did the controversy over slavery in the territories.

For some time during the American Civil War, the Fugitive Slave Acts were considered to still hold in the case of blacks fleeing from masters in border states that were loyal to the Union government. It was not until June 28, 1864, that the acts were repealed.

**fugue**, musical composition for instruments or voices, characterized by the systematic imitation of one main theme in simultaneously sounding melodic lines (counterpoint), which make up its texture. Fugue is more accurately described as a compositional procedure than a musical form, and its musical working out is traditionally in accordance with a set of fairly strict rules, though each example varies in specific form depending upon its type and the period in which it was written.

A brief treatment of fugue follows. For full treatment, see *MACROPAEDIA: Musical Forms and Genres*.

The roots of the fugue may be traced to the imitative polyphony of the 13th century, although it was not until the 16th century that fugal writing in its accepted sense emerged. It reached the culmination of its formal development and expressive effect in the works of Johann Sebastian Bach.

Fugue proceeds according to a certain pattern. It opens most commonly with the announcement of an unaccompanied theme, or "subject," that is taken up in turn by the other parts, or "voices." The range of this subject is

generally contained within one octave, but it may vary in length and character from a terse motif to a florid melody of several dozen notes. This initial announcement and working out of the themes, generally in the tonic key, is known as the "exposition." Its chief characteristic is the appearance of the subject at different pitches in each part. In the typical Baroque fugue, the interval of entry is normally at the fourth or fifth or at the octave to the original entry, and the second entry of the subject is often referred to as the "answer." Another characteristic feature of the fugal exposition is the countersubject, the continuation of the subject that forms the counterpoint to the answer. This theme regularly accompanies the subject on its appearances throughout the fugue. Should a countersubject accompany the first entry of the subject, however, it is known as the second subject and the fugue as a double fugue.

Passages between subsequent entries of the subject are called "episodes." Thematically they may be derived from the subject, countersubject, or codetta—the linking counterpoint between the subject and its answer. Fugues, however, sometimes exist without episodes, and by contrast they can appear with four or more expositions separated from each other by episodes. These middle expositions are often enriched by modulations to related keys with a return to the tonic key for the final exposition. This final section leads to the culmination of the music and may include such devices as stretto (the overlapping of subject and answer to increase intensity) or the pedal (where parts revolve around an elongated note, usually in the bass, to produce a series of dissonances prior to resolution). Such devices may occur in a small extension to the structure known as a coda.

**Führer**, also spelled *FUEHRER*, German *FÜHRER* ("Leader"), title used by Adolf Hitler to define his role of absolute authority in Germany's Third Reich (1933–45). As early as July 1921 he had declared the *Führerprinzip* ("leader principle") to be the law of the Nazi Party; and in *Mein Kampf* (1925–27) he asserted that such a dictatorship would be extended to the coming Third Reich.

A personality cult was built around the Führer. Hitler's portraits and photographs were displayed everywhere in Germany. "Heil Hitler!" ("Hail Hitler!") became legally obligatory as a common greeting, as did the Hitler salute of the right arm fully thrust forward with the palm facing downward.

Organizationally, the Führer stood at the apex of a hierarchy. Directly below him were several *Reichsleiter* ("Reich leaders") with various portfolios, such as finance, propaganda, foreign policy, and law, as well as *Reichsführer* Heinrich Himmler, head of the unified police system. Also directly responsible to (and selected by) the Führer were many territorial leaders (43 in greater Germany) known as *Gauleiter* ("district leaders").

**Fujayrah, Al-**, also spelled *FUJAJRAH*, constituent emirate of the United Arab Emirates (formerly Trucial States, or Trucial Oman). It is the country's only state with no territory on the Persian Gulf; its entire coastline is on the east side of the Oman promontory (the horn of southeastern Arabia), facing the Gulf of Oman. Because Al-Fujayrah's territory is divided or interrupted by exclaves (detached sections) of other emirates, its boundaries are partially undemarcated. Al-Fujayrah became a constituent emirate of the newly independent United Arab Emirates in 1971.

Economically, Al-Fujayrah is one of the poorer states of the country. There is some agriculture in the hilly areas away from the coast, where truck crops and tobacco are produced. Some fishing boats are headquartered in the small ports along the Gulf of Oman. Boat building is important, and several mar-

ble and tile factories have been built at Al-Fujayrah town. The principal urban centre is Al-Fujayrah town, the capital. Since the opening of its new container port in the early 1980s, Al-Fujayrah town has become a major transshipment point. Area 500 square miles (1,300 square km). Pop. (2001 est.) 98,000.

**Fuji**, city, Shizuoka *ken* (prefecture), central Honshu, Japan. It faces Suruga Bay at the southern foot of Mount Fuji. It was a post station along the Tōkaidō ("Eastern Sea Road") during the Tokugawa period (1603–1867). The arrival of the Tōkaidō Line (railway) in 1909 contributed to rapid commercial and industrial development, and Fuji produces chemicals, electrical machinery, automobiles, and photographic film. Rice, vegetables, mandarin oranges, and watermelons are cultivated in the surrounding region. Fuji, which is accessible via the Shinkansen (bullet) train, serves as a base for the ascent of Mount Fuji. Pop. (2000 prelim.) 234,192.

**Fuji, Mount**, Japanese *FUJI-SAN*, also called *FUJIYAMA*, or *FUJI NO YAMA*, highest mountain in Japan, rising to 12,388 feet (3,776 m) near the Pacific coast in Yamanashi and Shizuoka *ken* (prefectures), central Honshu, about 60 miles (100 km) west of Tokyo. It is a volcano that has been dormant since its last eruption in 1707 but is still generally classified as active by geologists. The mountain's name, of Ainu origin, means "everlasting life." Mount Fuji, with its graceful conical form, has become famous throughout the world and is considered the sacred symbol of Japan. Among Japanese there is a sense of personal identification with the mountain, and thousands of Japanese climb to the shrine on its peak every summer. The mountain is the major feature of Fuji-Hakone-Izu National Park (1936).

Although Mount Fuji appears to be a simple cone-type volcano, it is in fact three separate volcanoes, Komitake, Ko Fuji, and Shin Fuji. The most recent, Shin Fuji ("New Fuji"), first became active about 10,000 years ago and has continued ever since to smolder or erupt occasionally. Over the millennia, the lava and other effusions from Shin Fuji have covered over the two older volcanoes, enlarged the slopes to their present expansive girth, and otherwise given the mountain its current tapered form. The mountain is part of the Fuji Volcanic Zone, a volcanic chain that extends from the Mariana Islands and the Izu Islands through Izu Peninsula on up to northern Honshu.

The base of the volcano is about 78 miles (125 km) in circumference and has a diameter of some 25 to 30 miles (40 to 50 km). At the summit of Mount Fuji the crater spans about 1,600 feet (500 m) in surface diameter and sinks to a depth of about 820 feet (250 m). Around the jagged edges of the crater are eight peaks—Oshaidake, Izudake, Jojudake, Komagatake, Mushimatake, Kengamme, Hukusan-dake, and Kukushidake.

On the northern slopes of Mount Fuji lie the Fuji Five Lakes (Fuji Goko), comprising, east to west, Lake Yamanaka, Lake Kawaguchi, Lake Sai, Lake Shōji, and Lake Motosu, all formed by the damming effects of lava flows. The lowest, Lake Kawaguchi, at 2,726 feet (831 m), is noted for the inverted reflection of Mount Fuji on its still waters. Tourism in the area is highly developed, with Lake Yamanaka, the largest of the lakes (at 2.5 square miles [6.4 square km]), being the focus of the most popular resort area. Southeast of Mount Fuji is the wooded volcanic Hakone region, well-known for its hot-springs resorts at Yumoto and Gōra.

A sacred mountain (one sect, the Fujikō, accords it virtually a soul), Mount Fuji is surrounded by temples and shrines, there being shrines even at the edge and the bottom of the crater. Climbing the mountain has long been a

religious practice (though until the Meiji Restoration women were not allowed to climb it). In early times pilgrims usually made the climb in white robes. Today more than

Mount Fuji, Japan

T. Okuda—Aspect Picture Library, London

100,000 people a year flock there, mostly during the climbing season (July 1 to August 26).

**Fuji Bank, Ltd.**, one of Japan's largest commercial banks. Headquarters are in Tokyo.

The bank originated in a money-lending operation established in the 1860s by Yasuda Zenjiro, the founder of the Yasuda business combine, or *zaibatsu*. In 1880 the business became the Yasuda Bank, the financial arm of the emergent combine. When the Yasuda *zaibatsu* was broken up after World War II, the bank was reorganized in 1948 under its present name. An affiliate of Fuji Bank, Yamaichi Securities, was one of Japan's largest brokerage houses until it collapsed in 1997. Two years later Fuji Bank, Dai-Ichi Kangyo Bank, and the Industrial Bank of Japan began to merge, forming the Mizuho Financial Group.

**Fujimori, Alberto** (b. July 28, 1938, Lima, Peru), president of Peru (1990–2000).

Fujimori, the son of Japanese immigrants, graduated in 1961 from the National Agrarian University in Lima before pursuing graduate studies abroad. He subsequently joined the faculty of his alma mater and was made rector there in 1984. In 1989 Fujimori began a grass-roots presidential campaign with a new political party.

In June 1990 he defeated the conservative candidate Mario Vargas Llosa in a runoff election. Soon after taking office, he instituted austerity measures to stabilize the economy. In 1992 the military supported his decision to dissolve Congress and call for a new constitution, which was promulgated the following year. Fujimori promoted neoliberal policies, such as privatizing state-owned companies, and he took credit for the country's successful antiterrorism campaigns. He was reelected in 1995, but many regarded his election to a third term in 2000 to be fraudulent and unconstitutional. Fujimori's government crumbled later that year after the head of the secret police was shown to have bribed a congressman. Fujimori left Peru and was granted Japanese citizenship in 2001.

**Fujinomiya**, city, Shizuoka *ken* (prefecture), Honshu, Japan, at the western foot of Mount Fuji. It developed around the Sengen (Asama) Shrine, the main shrine for the worship of Mount Fuji since the 9th century. During the early part of the Tokugawa period (1603–1867), the ruler Tokugawa Ieyasu built an inner shrine, hall of worship, and tower gate, which were partly reconstructed in 1925.

Fujinomiya has long prospered by the great

The gate to the Sengen (Asama) Shrine at Fujinomiya, Japan

Mitl and Joan Mann—CAMERAMANN INTERNATIONAL

influx of pilgrims and tourists, who are attracted by its shrine, temples, and beautiful gardens. The opening of a branch railway line to the city brought industrial development after 1868. Industries include the processing of dairy products and the manufacture of paper pulp, cameras, and photographic materials. Pop. (2000 prelim.) 120,233.

**Fujisawa**, city, Kanagawa *ken* (prefecture), Honshu, Japan, on Sagami Bay of the Pacific Ocean. It was a post town during the Tokugawa period (1603–1867) and is the site of the Shojoko Temple (Yugyo Temple; 1325), the main temple of the Buddhist Ji sect. After the Tokaido Line (railway) was opened in 1889, Fujisawa grew as a residential suburb of the Tokyo–Yokohama metropolitan area. The northern part of the city was the site of industrial development (automobiles, electric appliances) after World War II. To the south is Kugenuma beach and the resorts of Katase and Eno Island. The yacht harbour on Eno Island was the site of the sailing competitions of the Tokyo Olympic Games of 1964. Pop. (2000 prelim.) 379,151.

**Fujita Tōko** (b. May 3, 1806, Mito, Japan—d. Nov. 11, 1855, Edo [Tokyo]), one of the Japanese scholars who inspired the movement that in 1868 overthrew the feudal Tokugawa shogunate, restored direct rule to the emperor, and attempted to strengthen Japan to meet the challenge of Western imperialist powers.

Born into a high samurai family, Fujita succeeded his father in 1827 as the director of the Shōkōkan, the history-compiling institute of the great feudal fief of Mito. He helped Tokugawa Nariaki succeed as daimyo, or lord, of Mito in 1829 and, two years later, accompanied Nariaki to Edo and advised the shogunate to strengthen Japan's defenses and to ban any intercourse or trade with foreign powers. Such views later influenced those coalescing against the shogunate under the slogan "Revere the Emperor; Expel the Barbarians."

Fujita returned to Mito in 1841 and helped strengthen the fief's defenses, an activity that alarmed the shogunate and led to the confinement of Nariaki and Fujita in 1844. Fujita put the time to good use by writing his two-volume *Kōdōkanki jutsugi* (1849), setting forth his views of Japan's unique destiny.

Fujita returned to active politics in 1853, when the shogunate invited Nariaki to advise on defense and diplomatic problems posed by the arrival of a U.S. naval squadron under Commodore Matthew C. Perry, who demanded that Japan end its two centuries of isolation and open trade with the rest of the world.

Fujita's exposure to the negotiations with the Americans brought him to the view that concluding treaties with the Western powers would be inevitable. Shortly afterward, he was killed when his house collapsed during an earthquake.

**Fujitsu Limited**, one of Japan's largest electronics companies. Headquarters are in Tokyo.

Fujitsu was established in 1935 when it broke away from Fuji Electric Company, a joint venture started in 1923 by the Furukawa Mining Company and Germany's Siemens to develop electrical equipment.

In 1954 Fujitsu built the first Japanese commercial computer. Encouraged by the Japanese government, which in 1957 promulgated that Japanese microelectronics catch up with U.S. technology, Fujitsu joined with other Japanese companies to develop and manufacture semiconductor chips. In 1965 Fujitsu began to export computers and by the next year was producing integrated circuits.

In 1967 the company became Fujitsu Limited, acquired American technology, and began producing IBM-compatible mainframe computers. Fujitsu soon overtook IBM Japan as the leading manufacturer of computers in Japan. Fujitsu also runs NIFTY SERVE, Japan's largest comprehensive online service provider, with close to 3 million subscribers.

**Fujiwara FAMILY**, dynastic family that, by shrewd intermarriage and diplomacy, dominated the Japanese imperial government from the 9th to the 12th century.

*Basis of power.* The power and authority of the Fujiwara family rested not on military prowess but on political strategy and on the family's special relationship to the imperial family, which it carefully cultivated and exploited through the marriage of Fujiwara daughters to emperors. This meant that the Fujiwara daughters were empresses, that their grandsons and nephews were emperors, and that members of their family, including its lesser branches, received all the patronage. Thus, the Fujiwara clan chieftain, whether he held office or not, could manipulate the reins of government.

The Fujiwara also took care to combine with the Buddhist hierarchy in order to increase its influence. A precedent set by pious emperors, who shaved their heads and retired to monasteries, was employed by the Fujiwara to persuade independent-minded emperors to retire from worldly affairs. Nor did the family neglect economic power. It encouraged the landed gentry in the provinces to commend land to the Fujiwara, which resulted in greatly reduced taxes for the landowners—sometimes eliminating their tax obligations altogether—and permitted the Fujiwara to divert public revenues to the family coffers.

*Beginnings.* Although the Fujiwara rise to power was gradual, its founding in the 7th century foretold its future role and importance. Its founder, Nakatomi Kamatari (see Fujiwara Kamatari), was already in his day the de facto ruler of the country, for it was he, together with the heir apparent, who had earlier plotted and successfully carried out the overthrow of a powerful rival of the imperial house. It was to Kamatari, therefore, that a grateful prince, who became the emperor Tenji, entrusted the affairs of government. In the year of Kamatari's death, the emperor conferred on him the new family name of Fujiwara ("Wisteria Arbour"), in commemoration of the place where the two had conspired to oust their common rival.

Fuhito (see Fujiwara Fuhito), Kamatari's son, was the first to use the new name. And it was he who, by arranging the marriage of a daughter to Emperor Shōmu, began the policy of attaching his own family to the imperial

family. Fuhito's four sons each established a branch of the family, of which the Hokke, or Northern Branch, was to become the most influential.

But it was not until the latter half of the 9th century that Fujiwara power began to be felt. Yoshifusa (see Fujiwara Yoshifusa), who was father-in-law to the reigning monarch and grandfather of the heir apparent, at the Emperor's death succeeded in having the heir elevated to the throne as the emperor Seiwa at the age of nine. Yoshifusa, thereupon, had himself appointed regent—the first instance in Japanese history of a person not of royal blood being named to this position. This led to the practice of the Fujiwara persuading emperors to retire at a comparatively early age and of placing on the throne child emperors, for whom the Fujiwara acted as regents. During the next two centuries there were eight such abdications and seven child emperors.

*Control of the regency.* With a firm grip on the regency, the Fujiwara had seemingly gone as far as they could to become the de facto rulers without actually destroying or displacing the Imperial family. The only drawback to the regency was that it ended when the emperor reached his majority. This was remedied when Yoshifusa's nephew Mototsune (see Fujiwara Mototsune) established a new position more prestigious and powerful than that of regent or prime minister—the office of *kampaku* (chancellor), whose function was to serve as the emperor's spokesman and intermediary between the throne and the officialdom. In practice it was a chancellorship and the highest office in the land, second only to the emperor and sought by all subsequent leaders.

The Fujiwara monopoly of government in the 9th century was interrupted only briefly when the emperor Uda, who did not have a Fujiwara mother, ascended the throne in 887. Uda, moreover, managed to reign without a Fujiwara regent and, in the last six years of his reign, without a Fujiwara *kampaku*, because of the death of Mototsune.

Mototsune's son, Tokihira (see Fujiwara Tokihira), only 21 years old at his father's death, quickly re-established Fujiwara domination. Tokihira never advanced to the office of *kampaku*, yet he effectively removed or neutralized opposition to the family. Among his rivals was a celebrated and beloved scholar-statesman, Sugawara Michizane, who was falsely accused of conspiring to place his own grandson on the throne and was banished to distant Kyushu. Other rivals were given sinecures to monasteries and lectureships in Chinese history by the resourceful Tokihira and were thus effectively removed from politics. That he was able to accomplish these moves from a relatively low position demonstrated that the Fujiwara, whether in high office or not, were the real rulers of the country.

*Peak of Fujiwara power and glory.* It was Michinaga (see Fujiwara Michinaga), however, who epitomized Fujiwara power and glory. He gave three daughters to emperors and a fourth to an heir apparent who later became emperor. Four grandsons were emperors, and a son was a regent. For 30 years he basked in the splendour and sophistication of court life. His mansions, more magnificent than the palaces of the emperors, were the scene of frequent banquets, concerts, poetry contests, and picnics. It is this brilliant if effete and frivolous court life that Murasaki Shikibu, a contemporary, described in her great novel *Genji monogatari* (*The Tale of Genji*, 1935). Michinaga also inspired still another contemporary romance, the *Eiga monogatari* (*A Tale of Flowering Fortunes*, 1980), by an unknown author.

But, in the midst of Michinaga's glory at the

capital, Fujiwara power was rapidly declining in the provinces. As early as the 940s there were two serious rebellions in the provinces, which were suppressed for the government by warrior families allied with the Fujiwara. But the victories served only to increase the power and popularity of the military families, to whom, rather than to the Fujiwara, the landed gentry tended to commend more and more of their lands. The failure of the Fujiwara to check this practice brought the rapid erosion of the economic basis of Fujiwara power and the strengthening of the military families of the outlying provinces.

*Last years.* The passing of Michinaga in 1027 hastened the decline of the family, which could neither prevent the emperor Go-Sanjo, who did not have a Fujiwara mother, from taking the throne in 1068 nor stop the establishment of a unique scheme of administration aimed at weakening Fujiwara control of the government. Known as *insei*, or "cloistered rule," this scheme called for the emperor to abdicate, leaving an infant on the throne, and to establish a separate administration in a monastery, from where, as a lay priest and free of Fujiwara overlordship, he would attempt to rule.

The *insei* definitely weakened Fujiwara influence in the 11th century, and the Fujiwara family was eliminated as a power at the court in the 12th century. In the Hōgen Disturbance of 1156 the contender supported by the Minamoto, a warrior family allied with the Fujiwara, lost to the emperor Shirakawa, supported by the warrior family of the Taira. In the Heiji Disturbance of 1159, the Minamoto-Fujiwara forces, who attempted to wrest back control of the court from the Taira, were ignominiously defeated. And thus, ironically, the Fujiwara, who for three centuries had eschewed violence and who had looked down contemptuously on the crude, unlettered warrior, were vanquished by violence and replaced as rulers by the very objects of their contempt. If there was any consolation for the Fujiwara, it was the knowledge that the House of Taira promptly adopted and helped to perpetuate the life-style and the political and social institutions that the Fujiwara had established. (M.Sh.)

**BIBLIOGRAPHY.** A complete translation of the *Ōkagami* ("Great Mirror"), written by an unknown author in the 11th century and covering the period from 850 to 1025, the period of Fujiwara domination, is now available: Joseph K. Yamagiwa (trans.), *The Ōkagami: A Japanese Historical Tale* (1967). A more recent general history that gives considerable attention to the subject is George Sansom, "The Fujiwara Regents," in *A History of Japan*, vol. 1 (1958). Two indispensable reference works in Japanese are: Ota Akira, *Seishi kakei dai-jiten* (Dictionary of Families and Genealogies), rev. ed., 3 vol. (1963), and *Dai Nihon jinmei jisho* (Biographical Dictionary of Japan), rev. ed., 5 vol. (1937).

**Fujiwara Dokai** (historian): see Jien.

**Fujiwara Fuhito** (b. 659, Japan—d. Sept. 9, 720, Japan), Japanese statesman whose descendants formed the four houses of the Fujiwara family that dominated Japan between 857 and 1160.

Fuhito was the son of the famous Nakatomi Kamatari (614–669), who was granted the new surname Fujiwara as a reward for having helped plan the coup d'état that brought the emperor Tenji to the throne. Because of his father's prestige, Fuhito was given high court rank.

In 701 Fuhito headed the committee that drafted the Taihō code. Consisting of 11 volumes of general laws and 6 volumes of criminal laws, it was the first comprehensive law code promulgated in Japan. Revised in 718, it was then retitled the Yōrō code.

Two of Fuhito's daughters became Imperial consorts, and the emperor Shōmu (reigned

724–748) was his grandson—this marital connection between the Fujiwara and Imperial families was the basis of the Fujiwara's rise to power. All of Fuhito's four sons died in a smallpox epidemic in 737, resulting in a temporary eclipse of the family's fortunes. Their sons and grandsons continued the line; however, and, by the middle of the next century, the Fujiwaras dominated the court.

**Fujiwara Kamatari**, original name NAKATOMI KAMATARI, or KAMAKO (b. 614, Yamato Province, Japan—d. Nov. 14, 669, Yamato Province), founder of the great Fujiwara family that dominated Japan from the 9th to the 12th centuries.

In the early 7th century the powerful Soga family totally dominated the Japanese Imperial court. In 645, however, along with an Imperial prince who later reigned as the emperor Tenji (661–671), Kamatari murdered the head of the Soga family and carried out a coup d'état. As a reward for his services, Kamatari was given the position of minister of the interior, and in this role he was able to implement a series of far-reaching measures known as the "Reforms of Taika" (*Taika no kaishin*). *Taika*, meaning "great change," was the term adopted for this whole era in accord with the Chinese custom of counting time by arbitrary "year periods" (*nengō*). His reforms helped strengthen the power of the central government and transform the Japanese political and economic system into a small facsimile of T'ang China (618–907). In 669, as a reward for his services, Kamatari was given the new surname of Fujiwara, and under him the Fujiwara clan became firmly ensconced.

Kamatari's reforms were, in fact, an attempt to adapt the entire Chinese political and social system to Japan. Laws were codified, arable land was surveyed, and all households were registered. Both the private holdings of land and the private ownership by agricultural workers were abolished; former owners were appointed to supervise the property they had once owned, although theoretically they were considered employees of the central government, whose power was conspicuously enlarged. A new capital metropolitan region was established; the country was divided into provinces ruled by appointees of the central government; a series of new roads and post stations was constructed to improve communications with outlying districts; and a uniform system of taxes was introduced. These measures helped to complete the process of centralization and Sincization that the government had begun 100 years earlier.

**Fujiwara Michinaga** (b. 966, Kyōto—d. Jan. 3, 1028, Kyōto), the most powerful of the Fujiwara regents, during whose reign the Imperial capital in Kyōto achieved its greatest splendour, and the Fujiwara family, which dominated the Japanese court between 857 and 1160, reached the apogee of its rule.

Michinaga was the son of Kaneie, the previous head of the Fujiwara family, and he succeeded to the leadership of the clan after the death of his elder brother in 995. Michinaga never took the title *kampaku* (chancellor) but advanced through the regular Imperial offices until he was named great minister of state (*dajō daijin*) in 1017.

Michinaga was given the honorary title of Nairan, which allowed him access to the private papers of the palace. The emperor's authority was still acknowledged, but the real seat of the government was transferred from the Imperial palace to Michinaga's administration (*mandokoro*). Four separate emperors were forced to marry his daughters; two emperors were his blood nephews and three his grandsons.

Some of Japan's greatest literature was produced during Michinaga's dominance. The magnificence of his palace became the subject of many stories. The famous *Makura no sōshi*

("Pillow Book"), by the court lady Sei Shōnagon, contains many references to Michinaga; Prince Genji, the hero of the great Japanese novel *Genji monogatari* (*The Tale of Genji*), is supposed to be partially modelled on Michinaga.

Conditions in the countryside seriously disintegrated during Michinaga's reign, however, and many powerful warrior families in the provinces refused to acknowledge central control. For a while Michinaga was able to stabilize conditions in the capital by paying warriors of the Minamoto and Taira clans to act as a kind of supplementary police force, but, as the Fujiwaras declined, these bands gradually usurped much of the governmental power:

**Fujiwara Mototsune** (b. 836, Kyōto—d. Feb. 25, 891, Kyōto), Japanese regent, creator (in 880) of the post of *kampaku*, or chancellor, through which he acted as regent for four adult emperors until his death. This post allowed the Fujiwara family to dominate the Japanese government for more than three centuries.

Mototsune's uncle, and father through adoption, Yoshifusa, had acted as regent for the child emperor Seiwa, who ascended the throne in 858. Succeeding Yoshifusa as head of the Fujiwara family in 812, Mototsune assumed the post of regent when another minor succeeded to the throne four years later. In order to further increase his power, Mototsune created the post of *kampaku*, which allowed him to exercise complete control over the government. When in 884 the emperor Yōzei challenged his rule, Mototsune forced his abdication. Subsequent heads of the Fujiwara family followed Mototsune in dominating Japan, but not all took the title *kampaku*.

**Fujiwara Nobuzane** (b. 1176, Japan—d. 1265?, Japan), courtier, poet, and the leading Japanese painter in the 13th century, who carried on the tradition of realistic portrait painting begun by his father, Takanobu.

Of the many paintings attributed to Nobuzane, "The 36 Major Poets" is the best

"Zuishin Teiki Emaki," detail of handscroll of colour on paper attributed to Fujiwara Nobuzane, mid-13th century; in the Ōkura Shūkōkan Museum, Tokyo

By courtesy of Ōkura Shūkōkan Museum Tokyo

documented. Originally a painting on a single scroll, it was later divided into separate portraits. These portraits are outstanding examples of the *nise-e* ("likeness picture style"): thin angular outlines filled in with masses of dense colour to depict the stiff court robes and a few sketchy lines to evoke the facial features and convey the personality of the subject. *Nise-e* was continued by Nobuzane's son, Tametsugu, and by Tametsugu's son Korenobu and grandson Tamenobu.

**Fujiwara Sadaie**, also called TEIKA, or FUJIWARA TEIKA (b. 1162, Japan—d. Sept. 26, 1241, Kyōto), one of the greatest poets of his age and Japan's most influential poetic theorist and critic until modern times.

Fujiwara was the son and poetic heir of the gifted and influential Shunzei (or Toshinari, 1114–1204), compiler of the seventh Imperial anthology of Japanese poetry, *Senzaishū* (c. 1188; "Collection of a Thousand Years"). Teika hoped not only to consolidate Shunzei's poetic gains and add to them in his own

right but also to raise his family in political importance. He did not advance politically, however, until he was in his 50s.

As a literary figure, Teika was a supremely accomplished and original poet. His ideal of *yōen* ("ethereal beauty") was a unique contribution to a poetic tradition that accepted innovation slowly. In his poems of ethereal beauty, Teika employed traditional language in startling new ways, showing that the prescriptive ideal of "old diction, new treatment" inherited from Shunzei might accommodate innovation and experimentation as well as ensure the preservation of the language and styles of the classical past.

Teika's poems attracted the favourable notice of the young and poetically talented former emperor Go-Toba (1180–1239), who appointed him one of the compilers of the eighth Imperial anthology *Shin kokin-shū* (c. 1205, "New Collection of Ancient and Modern Times"). In 1232 Teika was appointed sole compiler of the ninth anthology, *Shinchokusenshū* ("New Imperial Collection"), thereby becoming the first person ever to participate in the compilation of two such anthologies.

During his 40s, Teika underwent a profound inner conflict that greatly hindered his creativity and modified his poetic ideals. The chief poetic ideal of his later years was *ushin* ("conviction of feeling"), an ideal advocating poetry in more direct, simple styles than the technically complex poetry of *yōen*. Teika's achievements in these later styles were impressive, but in his late years he was mainly occupied as a critic, editor, and scholar.

The best known of Teika's treatises and anthologies, regarded as scripture by generations of court poets, are: *Eiga taigai* ("Essentials of Poetic Composition"); *Shūka no daitai* ("A Basic Canon of Superior Poems"); *Hyakunin isshū* ("Single Poems by One Hundred Poets"); *Kindai shūka* (1209; "Superior Poems of Our Time"); and *Maigetsushō* (1219; "Monthly Notes").

**Fujiwara style**, Japanese sculptural style of the Late Heian period (897–1185), known also as the Fujiwara period. Although many sculptures at the beginning of the period are in essence continuations of the Jōgan style, by the middle of the period a radical change had occurred in the style of the principal icons. This was partly the effect of the advent of the new Jōdō sect of Buddhism, which relied more upon emotional appeal than did

Kichijō-ten (Sanskrit Mahāśrī; the goddess of good luck), Fujiwara style polychromed wood sculpture, late 12th century. Late Heian period; at Jōruri-ji, near Nara, Japan

Asuka-en Japan

the older esoteric sects; one needed simply to adore Amida to be saved.

The sculpted figures were still full and fleshy, but they were also more elegant and appeared to be lighter in weight. There is a complete use of polychrome, with an elaborate development of cut-gold, or *kirikane*, patterns on the draperies. The softness of modelling, quite unlike the powerful forms of earlier periods, is the result of a joined-wood technique invented by the sculptor Jōchō, which allowed the sculptor greater freedom and delicacy of expression. The facial type is aristocratic, almost effeminate, with a small rosebud mouth, high arching eyes, and a narrow, short, sharp nose. Remnants of older traditions persisted in this style, but these were overlaid by the new Fujiwara interest in decorative effect that is seen especially in the applied jewelry, which in earlier periods had been painted or modelled on the surface of the sculpture.

**Fujiwara Sumitomo** (d. 941, Iyo Province, Japan), notorious Japanese pirate leader. Originally a government official, he was dispatched by the court to eliminate pirates plaguing the Inland Sea, which connects central and south Japan. A traitor to the trust placed in him, Sumitomo became the leader of the pirates and other dissident local bands and thereby gained control of most of the strategic areas along the waterway before he was defeated in 941. His actions helped to weaken Japan's central government.

**Fujiwara Tadahira** (b. 880, Kyōto—d. Sept. 9, 949, Kyōto), Japanese statesman who assumed the leadership of the Fujiwara family in 909 upon the death of his brother Tokihira. Although in his later years Tokihira had begun to dominate the government, he had never assumed the title of *kampaku* (chancellor). The post had been created and first assumed by their father, Fujiwara Mototsune, and allowed to lapse by the emperor Uda (reigned 887–897), the first Japanese sovereign in several generations whose mother was not a Fujiwara. Under Tadahira's dictatorship rebellions broke out in the provinces, and banditry was so common that not even the Imperial Palace was secure. After Tadahira died, the Fujiwaras continued to hold the regency, except for one three-year period, until 1180.

**Fujiwara Takanobu** (b. 1142, Kyōto—d. March 19, 1205, Kyōto), leading Japanese portrait artist of his day. He created a type of simple, realistic painting, the *nise-e* ("likeness picture"), popular throughout the Kamakura period (1192–1333). Of his three surviving portrait paintings, all in the Jingō-ji in Kyōto, perhaps the most famous is that of Minamoto Yoritomo, the founder of the Kamakura government. The portrait is notable for its sharp angular outlines and large blocks of dense colour—innovations that were carried on by Takanobu's son, Nobuzane, and his descendants for several generations. Takanobu is also remembered as the half-brother of Fujiwara Sadaie, one of Japan's greatest poets.

**Fujiwara Teika**: see Fujiwara Sadaie.

**Fujiwara Tokihira** (b. 871, Kyōto—d. April 26, 909, Kyōto), Japanese Imperial minister who checked the efforts of the emperor Uda (reigned 887–897) to halt the domination of the Japanese government by the Fujiwara family. Tokihira's father, Fujiwara Mototsune, had created and occupied the post of *kampaku*, or chancellor, a position that gave him virtual control of Japan by allowing him to issue commands on behalf of the emperor.

Upon Mototsune's death, the 21-year-old Tokihira became the head of the Fujiwara family. The emperor Uda, however, kept the post of *kampaku* vacant, attempting to gov-

ern by relying on advisers from minor noble families. In grudging acknowledgment of Tokihira's administrative talent, Uda did appoint him to a high ministerial position. Uda's abdication in 897 brought to the throne his son, the emperor Daigo, who tried to continue his father's effort to check the power of the Fujiwaras. He was unable to resist the political maneuvering of Tokihira, however, who in 899 received the influential post of minister of the left (*sadaijin*). The post of minister of the right (*udaijin*) was then held by the scholar Sugawara Michizane. In 901 Tokihira managed to have his rival exiled to the distant southern Japanese island of Kyushu. Even though Tokihira never assumed the post of *kampaku*, he did in fact become the virtual ruler of Japan.

In an effort to halt the deterioration of the power of the central government in the countryside, Tokihira drew up a series of edicts designed to eliminate the tax-exempt status of the great lords and their domains. These reforms were unpopular with the elite and were only temporarily successful in checking some of the most flagrant abuses. Tokihira began work on the *Engi-shiki* ("Institutes of the Engi Period"), a compilation of administrative regulations; after his death it was completed by others and was presented at court in 927. Upon Tokihira's death, his brother Tadahira succeeded him and in 941 assumed the office of *kampaku*.

**Fujiwara Yorimichi** (b. 992, Kyōto, Japan—d. March 2, 1074, Uji, near Kyōto), imperial courtier who, as regent for three emperors, dominated the Japanese government for 52 years (1016–68). Yorimichi's failure to maintain control over the countryside and to prevent quarrels among his kinsmen, however, furthered the decline of the powerful Fujiwara family.

The central government's control over the countryside had deteriorated under Yorimichi's father, Michinaga, but Yorimichi maintained a luxurious court style and ignored the unrest in the countryside. As a result, banditry and rebellions were rife, and brigands even penetrated the capital, plundering the imperial palaces. The great lords in the provinces no longer bothered to send taxes to the capital, and the imperial revenues became so depleted that palace buildings began to fall into disrepair. Although in retirement after 1068, Yorimichi was able to prevent the emperor Go-Sanjō (reigned 1068–72), the first emperor in over a century whose mother was not a Fujiwara, from supplanting the Fujiwara domination of imperial rule. After Yorimichi's death, however, Go-Sanjō's son, Shirakawa, was able to supplant the Fujiwara clan, and his successors excluded the Fujiwara from imperial power for nearly 100 years.

Yorimichi is credited with converting a former villa at Uji, near Kyōto, into the Byōdō Temple, which has some of the most outstanding examples of Japanese Buddhist art.

**Fujiwara Yoshifusa** (b. 804, Kyōto, Japan—d. Oct. 7, 872, Kyōto), imperial courtier under whom the Fujiwara family began its three-century-long domination of the Japanese imperial government.

By the middle of the 9th century the Fujiwara clan had become powerful at court, mainly because of the consistent choice of its women as imperial consorts. In 857 Yoshifusa was appointed to the influential post of great minister of state (*dajō daijin*), a position the court had left vacant for several generations. The following year Yoshifusa had his nine-year-old grandson placed on the throne and had himself assigned as regent (*sesshō*), the first instance in Japan in which a commoner was made regent for a child sovereign.

**Fujiwara Yukinari** (b. 972, Japan—d. Jan. 3, 1028, Japan), Japanese calligrapher, known as one of the Sanseki ("Three Brush Traces"), in effect the finest calligraphers of the age. The others were Ono Tōfū and Fujiwara Sukemasa, and the three perfected the style of writing called *jōdai-yō* ("ancient style").

Yukinari was the son of a courtier. After the death of his father he was raised by his grandfather, Prince Kanenori. He held a succession of high government offices. His extant calligraphic works include his versions of *Wakan rōei shū* ("Collection of Japanese and Chinese Poems to be Sung") and of the anthology of Chinese poet Po Chū-i, *Haku Rakuten shikan* ("Poetry Volume of Haku Rakuten"). In addition, he wrote *Gonki* ("Diary of Gon"), his diary.

**Fujiyama** (Japan): see Fuji, Mount.

**Fukaya**, city, Saitama *ken* (prefecture), Honshu, Japan. It is situated between the Ara River and the Tone River. An early market and post town, it changed little before World War II. Ceramic-tile production was the main traditional industry. After 1960 two consecutive industrial projects were developed in the southern suburbs. A railway and expressway between Tokyo and Takasaki run through the city. Pop. (1994 est.) 100,097.

**Fukien**, Wade-Giles romanization FU-CHEN, Pinyin FUJIAN, *sheng* (provincc), in the People's Republic of China. It is located along China's southeast coast, northwest of the island of Taiwan. Fukien is bordered by the provinces of Chekiang to the north, Kiangsi to the west, and Kwangtung to the southwest and by the East China Sea to the northeast, the Taiwan Strait to the east, and the South China Sea to the southeast. The province's capital is Fu-chou, which means "happy city."

A brief treatment of Fukien follows. For full treatment, see MACROPAEDIA: China.

During the Southern Sung dynasty (1127–1279), Fukien became an important shipbuilding and commercial centre for overseas and coastal trade. Since that time Fukienese have settled in great numbers in Southeast Asia. The province declined when the Ming dynasty (1368–1644) banned maritime commerce and when the Ch'ing dynasty (1644–1911/12) pursued a policy of isolation. In 1842, after the first Opium War, the cities of Fu-chou and Amoy were opened to international trade. The province's coastal cities were occupied by the Japanese in World War II.

The Fukien region is one of the most picturesque in Asia, with wooded hills and winding streams, orchards, tea gardens, and terraced rice fields on the gentler slopes. About 95 percent of the province is mountainous. Fukien is crossed by several ranges of moderate elevation that run roughly parallel to the coast. The Wu-i Mountains, which form a formidable natural barrier between Fukien and the interior of China, reach a height of about 6,000 feet (1,800 m) in western Fukien. The province's rivers have for centuries provided the major means of transport. They flow into estuaries that form natural harbours, and their abundant water supplies are used for domestic consumption as well as for irrigation. The climate along the coastal area of the province is semitropical—very hot in summer, cool in winter. Typhoons visit the coast during the late summer and early autumn.

The Han (Chinese) make up 99 percent of the population. Only about one-fifth of the population of Fukien is urban. The province has four large cities: Fu-chou and Amoy, both important seaports, Ch'üan-chou, and Chang-chou.

Fukien is a net importer of food grains. Its chief crops are sugarcane (among the highest yields in China), peanuts (groundnuts), citrus, rice, and tea. Noncrop agricultural output comes from fisheries, animal husbandry, and

forestry. Fukien also has considerable mineral wealth, including coal, iron, copper, gold, graphite, and kaolin (China clay) for making porcelain.

The province's traditional isolation has been breached by the construction of modern roads and railways linking its cities to those of neighbouring provinces. A rail line tying Fu-chou and Amoy to the Chekiang-Kiangsi main line stimulated the growth of regional industrial centres in Fukien, such as Nan-p'ing (pulp and paper), San-ming (iron and steel), and Lung-yen (coal). Beginning in 1979 Fukien was empowered to establish special economic zones in specific parts of the province to attract foreign investment. Area 47,500 square miles (123,100 square km). Pop. (1993 est.) 31,160,000.

**Fukko Shintō**, English RESTORATION SHINTO, or REFORM SHINTO, school of Japanese religion prominent in the 18th century that attempted to uncover the pure meaning of ancient Shintō thought through philological study of the Japanese classics. The school had a lasting influence on the development of modern Shintō thought.

Kada Azumamaro (1669–1736) was a pioneer in the Fukko Shintō movement. Kamo Mabuchi (1697–1769) rejected both the Buddhist- and Confucian-centred interpretations of Shintō and stressed a morality of pure simplicity in accordance with the order of heaven and earth as preserved in ancient Japanese tradition. Kamo Mabuchi's disciple, Motoori Norinaga, rejected such a Taoist-oriented interpretation and insisted that Shintō was based on the revelation of an exalted deity of creation, Takamimusubi no Kami, by the sun goddess Amaterasu Omikami. Motoori devoted many years to a philological and theoretical interpretation of the *Kojiki* ("Records of Ancient Matters"), completing his commentary to that work in 1798. The last noted Fukko Shintō scholar was Hirata Atsutane (1776–1843), who sought to construct a Shintō theology, leaning heavily on the writings in Chinese of the Jesuits Matteo Ricci and Didacus de Pantoja.

**Fukuda Takeo** (b. Jan. 14, 1905, Gumma prefecture, Japan—d. July 5, 1995, Tokyo), Japanese financial specialist who was prime minister from 1976 to 1978.

Born into a wealthy farming family of Gumma *ken* (prefecture), Fukuda attended the finest schools and, upon graduating from Tokyo University (1929), immediately entered the Ministry of Finance. He was a member of the House of Representatives from 1952 on. His political career included tenures as minister of agriculture, of finance (three times), and of foreign affairs. When Fukuda successfully challenged Miki Takeo for the presidency of the Liberal-Democratic Party (LDP), he was also assured the post of prime minister. He assumed office in December 1976 under conditions of unrealistically high popular expectations. During his term in office the economic situation worsened when a new yen-dollar exchange rate was established, the bankruptcy rate rose, and unemployment soared. Trade relations with the West were strained when Japan built up a huge balance of payments surplus.

In the realm of foreign relations, Fukuda achieved greater success. The Fukuda Doctrine, enunciated in 1977, declared Japan's resolve to never again become a military power and to strive to strengthen its relations with the nations of Southeast Asia. Fukuda was also instrumental in concluding the 1978 treaty of peace and friendship with China.

Fukuda's promise to stabilize the economy remained unfulfilled after one year, and the public's trust in his leadership declined further when some LDP members were implicated in the Lockheed bribery scandals. Fukuda was forced to dissolve his cabinet in 1978.

**Fukui, ken** (prefecture), central Honshu, Japan, on the Sea of Japan coast. Its area of 1,619 square miles (4,192 square km) includes the low Fukui Plain, which is backed by high mountains. To the southwest, the prefecture extends along the coast of Wakasa Bay, which is broken by cliffs, deep embayments, and peninsulas. Paddy-rice agriculture on the plain and forestry in the mountains are the leading occupations in the prefecture. The prefectural capital, Fukui, and smaller towns on the plain form a major silk and synthetic textile centre. Electrical machinery is also built there. Near Fukui is the Eihei temple complex, a headquarters of the Sōtō sect of Zen Buddhism,

The Tojimoto cliffs on the coast of the Sea of Japan in Fukui ken (prefecture)

Akiharu Fujikura—Bon

founded in the 13th century. Pop. (1990) 823,595.

**Fukui Kenichi** (b. Oct. 4, 1918, Nara, Japan—d. Jan. 9, 1998, Kyoto), Japanese chemist, corecipient with Roald Hoffmann of the Nobel Prize for Chemistry in 1981 for their independent investigations of the mechanisms of chemical reactions.

Fukui took little interest in chemistry before enrolling at Kyoto University, where he studied engineering, receiving a Ph.D. in 1948. He was professor of physical chemistry at Kyoto from 1951.

In 1954 Fukui published his first exposition of the concept that the crucial process in many chemical reactions consists of an interaction between the highest occupied molecular orbital of one compound and the lowest unoccupied orbital of the other. In effect, one molecule shares its most loosely bound electrons with the other, which accepts them at the site where they can become most tightly bound. The interaction results in the formation of a new, occupied orbital that has properties intermediate between those of the two former ones. Fukui designated these labile orbitals "frontier orbitals" and provided examples of their significance in reactions that produce important classes of organic compounds.

**Fukuoka, ken** (prefecture), northern Kyushu, Japan. Fukuoka faces the Inland Sea on the northwest, Shimonoseki Strait (on the north), the Tsushima Strait, or Eastern Channel (west), and the Ariake Sea (south). It occupies an area of 1,916 square miles (4,963 square km). Rivers draining seaward have built up extensive plains. The western coast of Fukuoka is heavily indented.

Agriculture is carried out in the south, but Fukuoka is important mainly for its coal mines and industry, which are concentrated in the north. In 1963 the five cities of Moji, Kokura, Tobata, Yahata, and Wakamatsu were amalgamated to form Kita-Kyūshū, the

Bota-yama (coal waste) remaining from Chikuoh Coalfield, which ceased production after World War II, Iizuka, Fukuoka ken (prefecture), Japan

largest city and industrial complex in Kyushu. Two tunnels run under the Shimonoseki Strait, connecting the city with Honshu. The city is spanned by the Wakato Grand Bridge. Pop. (1990) 4,811,179.

**Fukuoka**, city and port, capital of Fukuoka ken (prefecture), Japan. It incorporates the former city of Hakata and is located on the southern coast of Hakata Bay. There, a *kamikaze* ("divine wind") scattered and sank a fleet of invading Mongols in 1281. An ancient port, it is now a regional commercial, industrial, administrative, and cultural centre. The city contains an active fishing (halibut and flounder) port. It also contains Kyushu University (1911). Hakata *ningyo* ("dolls"), elaborately costumed ceramic figurines found in most Japanese homes, are made there. Pop. (1990) 1,237,107.

**Fukurokuju**, also called FUKUROKUJIN (from Japanese *fuku*, "happiness"; *roku*, "wealth"; and *ju*, "longevity"), in Japanese mythology,

Fukurokuju, copy of a 15th-century painting, in the Museum für Völkerkunde, Vienna

one of the Shichi-fuku-jin (Seven Gods of Luck). He represents longevity and wisdom. Like Jurōjin, another of the seven, with whom he is sometimes confused, he is said to have once lived on earth as a Chinese Taoist sage. He is depicted frequently in small sculptures and paintings and on craft items as a short old man with a conspicuously high-domed, bald head. He is occasionally accompanied by a crane or by another animal associated with longevity, such as the deer or the tortoise. See also Shichi-fuku-jin.

**Fukushima, ken** (prefecture), northeastern Honshu, Japan, facing the Pacific Ocean. Its area of 5,322 square miles (13,784 square km) is mostly mountainous, and settlement is concentrated in small interior basins and along

Drying edible algae on the beach near Hisanohama in Fukushima ken (prefecture), Japan

W.H. Hodge

the coast. Inawashiro Lake, 40 square miles (100 square km) in area, occupies the centre of the *ken*. Fukushima *ken* contains the southern extension of Bandai-Asahi National Park, encompassing the region of volcanic Bandai and Azuma mountains. The lower volcano slopes are dotted with lakes and swamps, many of which were formed by the eruption of Mount Bandai in 1888. Numerous spas serve the area.

Fukushima *ken* is essentially agricultural, producing rice surpluses and such cash crops as tobacco, mulberry (silk), fruits, grains, and vegetables that are resistant to low temperatures. Forestry and fishing and the gathering of seaweed in coastal towns such as Hisanohama are also important. Coal mining is carried on at the Jōban coalfield near Kōriyama city. Industry is concentrated in a few cities such as Fukushima, the prefectural capital, and Kōriyama; cameras, silk and rayon yarn, silk textiles, fruits, *bonsai* trees, and *kokeshi* dolls are produced. Pop. (1990) 2,104,119.

**Fukuyama**, city, eastern Hiroshima *ken* (prefecture), Honshu, Japan, on the delta of the Ashida River, facing the Inland Sea. A small fishing village before the construction of the Fukuyama Castle in 1619, it developed as a commercial port for the surrounding region during the Tokugawa era (1603–1868). Its importance grew with the opening of the railway line between Kōbe and Moji in 1901. Fukuyama was heavily damaged during World War II, but industrialization has been rapid since 1964. Besides the traditional spinning industry, the manu-

Fukuyama Castle, Hiroshima prefecture, Honshu, Japan

factory of kotos (Japanese zithers), machinery, steel products, rubber, and processed foods is important. Pop. (1993 est.) 370,873.

**Fukuzawa Yukichi** (b. Jan. 10, 1835, Buzen, Japan—d. Feb. 3, 1901, Tokyo), Japanese author, educator, and publisher who was probably the most influential man outside government service in the Japan of the Meiji Restoration following the overthrow of the Tokugawa family in 1868. He led the struggle to introduce Western ideas in order to increase, as he repeatedly wrote, Japanese “strength and independence.”

As the younger son of an impoverished lower samurai, Fukuzawa had little chance for advancement. Hence he entered school in Nagasaki to study the new techniques of *rangaku* (“Dutch learning”)—the term the Japanese used to describe Western knowledge and science in the years when the Dutch were the only Westerners with access to Japan, before the country was opened to the West in the mid-19th century. After going abroad with the first Japanese missions to the West in 1860 and 1862, Fukuzawa wrote *Seiyō jijō* (“Conditions in the West”), a book that became popular overnight because of its simple and clear descriptions of the political, economic, and cultural institutions of the Occident. Continuing his efforts to introduce Western ways into Japan, he developed a lucid writing style and began the first attempts at public speaking and debating in Japan. In the xenophobic years before the Meiji Restoration (1868), Fukuzawa’s championing of Western ways provoked many attempts on his life. After the restoration, when the Japanese government began actively to seek foreign knowledge, Fukuzawa was often invited to enter government, but he refused, insisting on the need to develop an independent intelligentsia.

Fukuzawa wrote more than 100 books explaining and advocating parliamentary government, popular education, language reform, women’s rights, and a host of other causes. In 1868 he founded Keiō Gijuku, which developed into Keiō University in Tokyo, the first great university independent of government domination and one that was to produce many business leaders. In 1882 he founded the *Jiji shimpō* (“Current Events”), which was for years one of Japan’s most influential newspapers and a training ground for many liberal politicians and journalists. Writing in his *Autobiography* (Eng. trans. 1934) shortly before his death in 1901, Fukuzawa declared that the abolition of all feudal privileges by the Meiji government and Japan’s victory over China in the Sino-Japanese War of 1894–95 (which gave Japan the status of a world power) had fulfilled his life completely. His only regret was that many of his friends had not lived to see these great accomplishments.

**Fūl, Tall al-** (Israel): see Gibeah.

**Fulani**, also called PEUL, or FULBE, a primarily Muslim people found scattered in many parts of West Africa, from Lake Chad, in the east, to the Atlantic coast. They are concentrated principally in Nigeria, Mali, Guinea, Cameroon, Senegal, and Niger. The Fulani language, known as Fulfulde (Fula), is classified within the West Atlantic branch of the Niger-Congo family.

Interaction of the widely dispersed Fulani with disparate other groups has produced a variety of socioeconomic patterns. Originally, the Fulani were a pastoral people, their lives and organization dominated by the needs of their herds. Such pastoral Fulani today enjoy greater prestige than town and sedentary agricultural Fulani as the most truly representative of Fulani culture. Interaction with other groups has sometimes resulted in a considerable degree of cultural absorption. This is most notably the case in northern Nigeria, where perhaps half of the Fulani have adopted the Hausa (*q.v.*) language and culture, and where, as a result of a series of holy wars (1804–10), purporting to purify Islām, they established an empire, instituting themselves

Fulani chieftain riding up to salute the emir of Katsina at the end of the Muslim festival of Ramaḡān in northern Nigeria

Ken Heyman—Rapho/Photo Researchers

as a ruling aristocracy. The urban Fulani are the most ardently Muslim; pastoral Fulani are frequently lax and sometimes even pagan. The pastoralists also exhibit a much higher incidence of non-Negroid physical traits. They wander in nomadic groups, making temporary camps of portable huts. Some of their dairy produce is usually exchanged at markets for cereal foods; cattle are rarely killed for meat. Many sedentary Fulani, who frequently have become sedentary as a result of the depletion of their herds, also own cattle but rely principally on cultivation.

The social structure of the pastoral Fulani is egalitarian, in marked contrast to that of other Muslim groups, such as the Hausa, and to most sedentary Fulani. The influence of Islām on kinship patterns is evident in the general preference for cousin and other intralineaage marriages. Most men are polygynous, the typical household unit comprising the family head, his wives, and unmarried children.

**Fulani empire**, Muslim theocracy of the Western Sudan that flourished in the 19th century. The Fulani, a people of obscure origins, expanded eastward from Futa Toro in Lower Senegal in the 14th century. By the 16th century they had established themselves at Macina (upstream from the Niger Bend) and were proceeding eastward into Hausaland. Some settled in the 19th century at Adamawa (in the northern Cameroons). Many of the Fulani continued to pursue a pastoral life; some, however, particularly in Hausaland, gave up their nomadic pursuits, settled into existing urban communities, and were converted to Islām.

In the 1790s a Fulani divine, Usman dan Fodio (1754–1817), who lived in the northern Hausa state of Gobir (northeast of Sokoto) quarreled with its rulers. Accusing the Hausa kings of being little more than pagans, he encouraged the Hausa people to revolt. Joined both by Hausa commoners and by Fulani pastoralists alike, the jihad, or holy war, swept through Hausaland and, repulsed only by the eastern empire of Kanem-Bornu, engulfed Adamawa, Nupe, and Yorubaland to the south. After the invasion by the Fulani of the northern provinces of the Oyo, the emirate of Ilorin to the northeast became the base from which Islām was to spread among the Yoruba. Usman, who was more a scholar than a statesman, ceded the practical direction of the eastern part of the empire to his son Muḡammad Bello, who settled in Sokoto, and the western (with its capital at Gwandu) to his brother Abdullahi. All three continued the Fulani denunciation of Bornu. The empire reached its zenith under Muḡammad Bello, who, like Usman, administered it according to the principles of Muslim law. The decay of this system was to aid the establishment in the late 19th century of British rule over what was later to be known as Northern Nigeria.

**Fulbert of Chartres, Saint** (b. c. 960, Picardy region, France—d. April 10, 1028, Chartres; feast day April 10), French bishop of Chartres who developed the cathedral school there into one of Europe’s chief centres of learning.

Educated at Reims under Gerbert (later Pope Sylvester II), Fulbert was appointed chancellor of the cathedral of Chartres in 990, when he began his work on behalf of the school. His teaching gained him a reputation for erudition and determination in pursuit of the truth. As bishop of Chartres from 1006, Fulbert was sent on diplomatic missions to Rome by King Robert II, whom he supported in his conflict with the nobles of France and with William V of Aquitaine. In 1020 Fulbert began to rebuild the burned cathedral of Chartres, but he died before the work was completed.

**Fulbright, J. William**, in full JAMES WILLIAM FULBRIGHT (b. April 9, 1905, Sumner, Mo., U.S.—d. Feb. 9, 1995, Washington, D.C.), American senator who initiated the international exchange program for scholars known as the Fulbright scholarship. He is also known for cosponsoring

Fulbright

Alfred Eisenstaedt—Time-Life Picture Agency © 1964-72 Time Inc

the censure resolution against Sen. Joseph R. McCarthy in 1954 and for his vocal and articulate criticism of U.S. policy toward Vietnam during his tenure as chairman of the Senate Foreign Relations Committee.

Fulbright graduated from the University of Arkansas, then went to Oxford—where he earned two degrees—as a Rhodes Scholar. Back in the United States, he received his law degree from George Washington University (Washington, D.C.) and taught law at the University of Arkansas, serving as president of the latter from 1939 to 1941.

In 1942 Fulbright won a seat in the House of Representatives, thus beginning a political career that was to last more than three decades. His most notable achievement in the House was the 1943 Fulbright Resolution, putting the House on record as favouring U.S. participation in a postwar international organization. This organization at its founding in 1945 was named the United Nations.

In 1944 Fulbright ran successfully for the Senate. The following year the Senate passed the Fulbright Act, establishing an educational exchange program between the United States and foreign countries. During the 1950s, he became increasingly skeptical about the "containment" policy and the dominant view that Communism was an aggressive monolith that must be resisted wherever it appeared.

Fulbright voted against funding for Senator McCarthy's anti-Communist investigations, an action that made him popular among liberals. He consistently opposed efforts to integrate schools and promote the civil rights of blacks, however, making it possible for him to be reelected from Arkansas in 1950, 1956, 1962, and 1968.

As chairman of the Senate Foreign Relations Committee (1959–74), Fulbright advised President Kennedy not to invade Cuba, and he vigorously opposed President Johnson's 1965 intervention in the Dominican Republic.

The American public came to know Fulbright best for his probing, articulate opposition to the war in Vietnam. While he voted for the Gulf of Tonkin Resolution (1964; *q.v.*), Fulbright later regretted that vote and claimed he had been deceived by President Johnson. In 1966 his committee held televised hearings on U.S. policy toward Vietnam and China, one result of which was to make antiwar protest respectable.

Viewed as a Washington "insider" at a time when that was considered a liability, Fulbright lost his 1974 bid for reelection. He presented his views of U.S. foreign policy in a number of books, including *Old Myths and New Realities* (1964), *The Arrogance of Power* (1967), and *The Crippled Giant* (1972).

**Fulbright scholarship**, educational grant under an international exchange scholarship program created to increase mutual understanding between the people of the United States and the people of other countries through the medium of educational and cultural exchange. The program was conceived by Sen. J. William Fulbright of Arkansas and carried forward by the Fulbright Act of 1946 and subsequent legislation, consolidated and expanded in the Mutual Educational and Cultural Exchange Act of 1961, the Fulbright-Hays Act.

The Fulbright program is based on a series of bilateral diplomatic agreements that place ultimate responsibility for operations with the U.S. Department of State. Overseas administration, however, is turned over to educational foundations in which signatory governments and their academic communities participate; some other governments share the program's costs with the United States.

A candidate for a Fulbright grant must be under 35 years of age, have a bachelor of arts degree or its equivalent, be proficient in the language of the country in which he pro-

poses to study, and have general maturity and scholastic competence. Most of the exchanges have been students, but teachers, advanced researchers, trainees, and observers have also qualified.

**Fulcher OF CHARTRES** (b. c. 1059, Chartres, Fr.—d. c. 1127, Jerusalem), French chaplain and chronicler of the First Crusade.

Apparently educated for the priesthood in Chartres, Fulcher attended the Council of Clermont and accompanied his overlord, Stephen of Blois, to southern Italy, Bulgaria, and Constantinople in 1096. In June 1097 he became chaplain to Baldwin of Flanders, with whom he remained. He went to Jerusalem in the winter of 1099 with Baldwin and spent the rest of his life there. His *Gesta Francorum Jherusalem peregrinantium* (written in three installments, 1101, 1106, and 1124–27) is a vivid and reliable account of the First Crusade, Baldwin's journey to Jerusalem, and the Kingdom of Jerusalem to 1127.

Despite his loyalty to Baldwin, Fulcher remained quite objective and provided a restrained portrait of the Byzantine Empire.

**Fulcodi, Guido** (pope): see Clement IV.

**Fulda**, city, Hesse Land (state), central Germany, situated on the Fulda River between the Rhön and Vogelsberg mountains. It developed around a Benedictine abbey founded in 744 by Sturmi, a disciple of St. Boniface. The abbey became a missionary centre, and its school was one of Europe's important seats of learning during the early Middle Ages, after Rabanus Maurus (*q.v.*) became its director in 803. It employed 12 manuscript copyists, and its great library survived until the 17th century. Fulda was chartered in 1157 and became a prince-abbacy; it was converted to a prince-bishopric when its abbot acquired the rank of bishop in 1752. It was the seat of a university during 1734–1803. The principality was secularized in 1802, passed to Hesse-Kassel in 1815, and was annexed by Prussia in 1866.

Most of the noteworthy buildings form an integrated Baroque district, including the cathedral (1704–12; with the crypt of St. Boniface); the episcopal palace (1707), now the city hall and museum; and the Orangery, before which stands the Floravase (1728), carved out of a single piece of stone. The Church of St. Michael dates from about 820, and the Probstei Church at Petersburg (just outside Fulda) is also 9th century. The Frauenberg Franciscan monastery (rebuilt 1760) is to the north of the city. Adolphseck Castle (1730–50) nearby, a former summer residence of the prince-bishops, is now a museum. The Land library contains a number of books from the monastic library. Fulda is the administrative centre for the neighbouring Hessische Rhön nature park.

Fulda is a substantial banking and financial centre. The major manufactures are textiles and clothing. Pop. (1989 est.) 54,320.

**Fulda River**, river, central Germany, a tributary of the Weser River. It rises on the Wasserkuppe (mountain) in the Rhön mountains and flows generally northward past the cities of Fulda, Bad Hersfeld, Melsungen, and Kassel. The main tributary is the Eder River, which joins it from the west above Kassel. The Fulda unites with the Werra at Münden to form the Weser River after a course of 135 mi (218 km).

The river valley, flanked on the left by the Vogelsberg, Knüll, and Habichtswald highlands and on the right by the Rhön and the Thüringer Wald, served as a trade route between southern and northern Germany during the Middle Ages, and the upper course of the river formed part of the boundary between East and West Franconia before 1100. Today the Fulda basin, apart from the industrial city of Kassel, is a region of wooded hills, farms,

and recreational areas including the Edersee reservoir, ski slopes, and several spas.

**Fulgentius OF RUSPE, SAINT** (b. c. 467, Telepte, North Africa—d. Jan. 1, 533, Ruspe; feast day January 1), African bishop of Ruspe and theological writer who defended orthodoxy in 6th-century Africa against Arianism (*q.v.*). He also wrote polemics against Semi-Pelagianism (*q.v.*), the doctrine condemned at the Council of Orange (529).

Fulgentius became a monk, residing successively in Africa, Sicily, and Rome, then accepted the African bishopric of Ruspe on the Mediterranean coast (507). In 508 the Vandal king Thrasimund, a supporter of Arian beliefs, exiled 60 orthodox African bishops, who settled in Sardinia with Fulgentius as their leader and spokesman. Thrasimund recalled Fulgentius (515), but because of his orthodoxy, Fulgentius was exiled again (517–523). Thrasimund's successor, Hilderich, allowed Fulgentius to return to Africa.

Eight of the numerous, essentially polemical writings ascribed to him elaborating orthodox views are known to be authentic. He was such a fervent disciple of St. Augustine that he has been called the "abbreviated Augustine."

**Fulgentius, Fabius Planciades** (fl. late 5th and early 6th centuries AD), Christian Latin writer of African origin, a mythographer and allegorical interpreter of Virgil. Though his writings are mediocre and fantastic, they exerted a great deal of influence on scholars of the Middle Ages, who followed his method of using allegory to interpret classical writers.

Fulgentius is the author of the *Mitologiarum libri iii*, containing allegorical interpretations of myths supported by absurd etymologies, and of an *Expositio Vergilianae continentiae secundum philosophos morales*, in which he makes Virgil himself appear in order to reveal the mystic meaning of the *Aeneid*. He also wrote an *Expositio sermonum antiquorum*, explanations of 62 rare Latin words supported by quotations, some of them from authors and works that never existed; and a *Liber absque litteris de actibus mundi et hominis*, a bizarre work in which human history is divided into 23 periods. His youthful poems and a work entitled *Physiologus* are lost.

It was once thought that Fulgentius might be identical with St. Fulgentius of Ruspe, but that idea has been largely abandoned.

**fulgurite**, a glassy silica mineral (lechatelierite) fused in the heat from a lightning strike. Fulgurite is a common mineral with two varieties. Sand fulgurites, the more common, are branching, more or less cylindrical tubes that are about one centimetre (one-half inch) to several centimetres in diameter; they are commonly less than 3 metres (10 feet) long but sometimes reach 20 m (66 ft). The central cavity is usually lined with glass, and the exterior shows adhering sand grains. The shores of Lake Michigan and the Atlantic coast are typical sites.

Rock fulgurites, the other variety, are thin, glassy crusts on rocks. They generally occur on mountain summits, as at Toluca, Mex., and Mt. Thielsen, Oregon.

**Fulham** (England): see Hammersmith and Fulham.

**Fuligo**, genus of true slime molds (class Myxomycetes; *q.v.*) whose large fruiting body (compound sporangia), 5 centimetres (2 inches) or more long and about half as wide, occur commonly on decaying wood. The sporangia, on bursting, release fine black spores. *Fuligo septica*, the best-known species, is also called "flowers of tan," from the frequent appearance of its yellow fruiting body in tan bark bits used for tanning hides.

**Fulk**, also spelled FULKE, French FOULQUES, or FOULQUE, name of rulers grouped below by country and indicated by the symbol ●.

## ANJOU

● **Fulk III NERRA**, byname FULK THE BLACK, French FOULQUES LE NOIR (b. c. 970—d. June 21, 1040, Metz, Fr.), count of Anjou (987–1040), the most powerful of the early rulers of the Angevin dynasty.

Exposed at first to the attacks of the counts of Brittany, Fulk had to fight for a long time to defend his frontiers, finally driving the Bretons back beyond the frontiers of Anjou. Having made himself master in the west, he turned his attention to the east and came into conflict with the count of Blois, Eudes II, over the territory of Saumur and a considerable part of Touraine. He defeated Eudes at Pontlevoy in 1016 and surprised and took Saumur 10 years later.

A ruthless warrior who burned and pillaged the monasteries in his path, Fulk nevertheless felt the need for penance, making three pilgrimages to the Holy Land and founding or restoring several abbeys, including those in or near Angers, Loches, and Saumur. He also built strongly fortified castles of stone (instead of wood) along the border of his territory. For this reason he was called le Grand Bâtitseur ("the Great Builder"). He died on his return from a pilgrimage to the Holy Land, having reigned 53 years.

● **Fulk IV**, byname FULK THE SURLY, French FOULQUES LE RÉCHIN (b. 1043, Château Landon, Fr.—d. April 14, 1109, Angers), count of Anjou (1068–1109).

Geoffrey II Martel, son of Fulk III, pursued the policy of expansion begun by his father but left no sons as heirs. The countship went to his eldest nephew, Geoffrey III the Bearded. But the latter's brother, Fulk, discontented over having inherited only a few small appanages, took advantage of the general discontent aroused by Geoffrey III's inept rule, seized Saumur and Angers (1067), and cast Geoffrey first into prison at Sablé and later in the confines of Chinon castle (1068). Fulk's reign then had to endure a series of conflicts against the several barons, Philip I of France, and the duke of Normandy. He lost some lands but secured, through battle and marriage, the countship of Maine for his son, Fulk V.

● **Fulk V**: see Fulk (Jerusalem).

## JERUSALEM

● **Fulk**, byname FULK THE YOUNGER, French FOULQUES LE JEUNE (b. 1092—d. November 1143, Acre, Palestine [now 'Akko, Israel]), count of Anjou and Maine as Fulk V (1109–31) and king of Jerusalem (1131–43).

Son of Fulk IV the Surly and Bertrada of Montfort, he was married in 1109 to Arenburga of Maine. Fulk exerted his control over his vassals and was later caught up in dynastic quarrels between the French and English kings. In 1128 his son Geoffrey Plantagenet married Matilda, daughter of Henry I of England, and became the progenitor of England's branch of the Angevin dynasty. Fulk first visited Palestine in 1120 and returned in 1129 to marry Melisend, daughter of King Baldwin II of Jerusalem.

Fulk became king of Jerusalem on Baldwin II's death in 1131 and spent the first year of his reign settling a dispute in Antioch (Turkey) and putting down a revolt led by his wife's lover, Hugh of Le Puiset. In 1137 he allied himself with the Byzantines against a Turkish leader, 'Imād ad-Dīn Zangī, of Mosul (Iraq), and in 1140 helped the Muslims of Damascus ward off Zangī's armies. He protected

Jerusalem in the south by constructing a series of fortresses, including Krak of Moab.

**Fulk**, ARCHBISHOP OF REIMS, French FOULQUES, or FOULQUE, ARCHEVÊQUE DE REIMS (d. June 17, 900), leader of the opposition to the non-Carolingian king Eudes (of the West Franks, or France).

Failing to establish his kinsman, Guy II of Spoleto, as king of the West Franks in 888, Fulk turned unavailingly to Arnulf, king of the East Franks, and then to the young Charles, son of the Carolingian Louis II the Stammerer; he crowned Charles at Reims in 893. His view was that only one of Carolingian blood could rightfully become king. Although Charles had to yield to Eudes, he became king (as Charles III) on the latter's death in 898, and Fulk became his chancellor. Fulk's efforts to keep church property out of the hands of the nobles provoked his assassination in 900 at the instigation of Count Baldwin II of Flanders.

**Fuller, Andrew** (b. Feb. 6, 1754, Wicken, Cambridgeshire, Eng.—d. May 7, 1815, Kettering, Northamptonshire), English Baptist minister and theologian. He is remembered as a founder and first secretary of the Baptist Missionary Society.

In 1770 Fuller joined the Soham Baptist Church, Cambridgeshire, and five years later became its pastor. After moving in 1782 to Kettering, Fuller became a leader of the Northampton Baptist Association and a close friend of William Carey, John Ryland, and John Sutcliff. This group of young men was responsible, at the instigation of Carey, for the formation in 1792 of the English Baptist Missionary Society, and Fuller's main activities, in addition to his Kettering pastorate, were connected with the affairs of this society. He traveled to all parts of the country, pleaded for money, and conducted an extensive correspondence in the interests of enterprises in Sierra Leone, Ceylon, and Jamaica, as well as India.

**Fuller, George** (b. Jan. 17, 1822, Deerfield, Mass., U.S.—d. March 21, 1884, Brookline, Mass.), American painter noted for his haunting, dreamlike pictures of figures set in landscape—e.g., "The Tomato Patch."

He began his formal training at the studio of Henry Kirke Brown. At first an itinerant portraitist, he settled in New York City about 1847 and enjoyed moderate success there. After the death of his father and brother in 1859, Fuller retired to Deerfield to assume responsibility for the family farm. He continued to paint for pleasure, and, in 1876, pressed for money, he sent some paintings to Boston. They attracted much attention, and he never thereafter lacked patrons. Fuller is especially remembered for his introspective later works, notably "The Quadroon" and "Romany Girl."

## Consult the INDEX first

**Fuller, Henry Blake** (b. Jan. 9, 1857, Chicago, Ill., U.S.—d. July 28, 1929, Chicago), American novelist who wrote about his native city of Chicago.

Fuller came from a prosperous Chicago family and attended the city's schools. After a foray into business he lived for a year abroad, mostly in Italy, to which he returned several times. His first two novels—*The Cavalier of Pensieri-Vani* (1890; written under the pseudonym Stanton Page) and *The Chatelaine of La Trinité* (1892)—were gracefully told, brief but unhurried tales about Europe.

Fuller took a decidedly different direction with *The Cliff-Dwellers* (1893), a realistic novel, called the first important American city novel, about people in a Chicago skyscraper. *With the Procession* (1895) was another realistic novel about a wealthy Chicago merchant family and the efforts of some of its members

to keep up with the city's wealthy ruling class. His other fiction set in Chicago includes *Under the Skylights* (1901), short stories about the city's artistic life; *On the Stairs* (1918), a novel about two men, one going up in life, the other down; and *Bertram Cope's Year* (1919), which is about an instructor at the University of Chicago. He continued his European-based fiction with *Waldo Trench and Others* (1908), stories about Americans in Italy; and *Gardens of This World* (1929), which extends the tale begun in his first book.

Fuller helped establish the book review section of the *Chicago Evening Post* (1901–02) and wrote editorials from 1911 to 1913 for the *Chicago Record-Herald*.

**Fuller, J(ohn) F(rederick) C(harles)** (b. Sept. 1, 1878, Chichester, Sussex, Eng.—d. Feb. 10, 1966, Falmouth, Cornwall), British army officer, military theoretician, and war historian who became one of the founders of modern armoured warfare.

Commissioned into the British Army in 1899, Fuller saw service in the South African War and was a staff officer in France during World War I. As chief of staff of the British tank corps from December 1916, he planned the surprise attack of 381 tanks at the Battle of Cambrai on Nov. 20, 1917; this was the first massed tank assault in the history of warfare. After the war he launched a crusade for the mechanization and modernization of the British army. Chief instructor of Camberly Staff College from 1923, he became military assistant to the chief of the imperial general

J.F.C. Fuller  
Bassano & Vandyk, London

staff in 1926. He was promoted to major general in 1930 and retired three years later to devote himself entirely to writing.

Throughout the interwar period, Fuller wrote voluminously, his most notable works being *Tanks in the Great War* (1920), *The Reformation of War* (1923), *On Future Warfare* (1928), and *Memoirs of an Unconventional Soldier* (1936). His lectures (*Field Service Regulations III*, 1937) were adopted for study by the general staffs of the German, Soviet, and Czechoslovak armies. But in glorifying the tank as an almost independent and irresistible land battleship, Fuller was considered extreme, and his emphasis on the armoured offensive alienated English military tacticians who were still imbued with the defensive doctrines of World War I.

Fuller served as a reporter during the Italian invasion of Ethiopia (1935) and the Spanish Civil War (1936–39) and was the only foreigner present at Nazi Germany's first armed maneuvers in 1935. Seeing his teachings largely vindicated by World War II, he produced *Machine Warfare* in 1942 and wrote one of the first histories of the conflict, *The Second World War 1939–1945* (1948). His most comprehensive work was *A Military History of the Western World*, 3 vol. (1954–56), in which he analyzed Western warfare from its beginnings through World War II.

**Fuller, Loie**, original name MARIE LOUISE FULLER (b. Jan. 15, 1862, Fullersburg, Ill., U.S.—d. Jan. 1, 1928, Paris), American dancer

who achieved international distinction for her innovations in theatrical lighting as well as

Loie Fuller

for her invention of the "serpentine dance," a striking variation on the popular "skirt dances" of the day.

She made her debut as an actress at the age of four. After touring as a child prodigy, she acted in stock companies, burlesque, vaudeville, and Buffalo Bill's Wild West Show.

A popular, if not authenticated, explanation of the origin of her experimentation with voluminous and luminous draperies claims that, during rehearsals for a play, *Quack, M.D.*, in 1889, Fuller received a gift of a long, full skirt of transparent china silk. Inspired by its billowing folds, she experimented with lengths of silk manipulated under lights of various colours, with spectacular results. She called her creation the "serpentine dance." In her equally successful "fire dance" she danced on a pane of glass, illuminated from below.

Appearing at the Folies-Bergère, Paris, in 1892, Fuller attracted the attention of such artists as Toulouse-Lautrec, Jules Chéret, and Auguste Rodin. She had her own theatre at the Paris Universal Exposition of 1900. In 1909 she toured the U.S. and in 1923 staged an inferno scene for a Paris Opéra production of Berlioz' *Damnation de Faust*. After another tour of the U.S. in 1926, she made her last appearance in London the next year.

**Fuller, (Sarah) Margaret**, married name MARCHESA (Marchioness) OSSOLI (b. May 23,

Margaret Fuller, engraving by R. Babson and J. Andrews, c. 1860

By courtesy of the Library of Congress, Washington D C

1810, Cambridgeport, Mass., U.S.—d. July 19, 1850, at sea), U.S. critic, teacher, and woman of letters whose efforts to civilize the taste and enrich the lives of her contemporaries make her significant in the history of American culture.

Fuller's father, raising her in the fashion of a son, made of her a "youthful prodigy," but later she blamed her father for her broken health, asserting that the vicarious experience of books should never take the place of actual experience tempered with sympathy and interpretation.

Plagued by financial difficulties after her father's death in 1835, she taught in Bronson Alcott's Temple School in Boston, 1836-37, and in Providence, R.I., 1837-39. In 1839 she published a translation of *Eckermann's Conversations with Goethe*, her most cherished project, never completed, was a biography of Goethe. In 1840 her friendship with Ralph Waldo Emerson and her critical essays won her the position of editor of *The Dial*, a magazine launched by the Transcendentalists. She wrote poetry, reviews, and critiques for the quarterly, but in 1842 she had to relinquish the unprofitable editorship to Emerson.

For five winters, 1839-44, she conducted in Boston classes of "conversations" for women on literature, education, mythology, and philosophy, in which venture she was reputed to be a dazzling leader of discussion. Her professed purpose was "to systematize thought"; more generally, she attempted to enrich the lives of women and to dignify their place in society. The same purpose guided her in writing *Woman in the Nineteenth Century* (1845), a tract on feminism that was both a demand for political equality and an ardent plea for the emotional, intellectual, and spiritual fulfillment of women. It was published by Horace Greeley, who had admired her *Summer on the Lakes, in 1843* (1844), a perceptive study of frontier life in Illinois and Wisconsin.

In 1844 Margaret Fuller became literary critic on Greeley's newspaper, the *New York Tribune*. She encouraged American writers and crusaded for social reforms but made her greatest contribution, she thought, as an interpreter of modern European literature.

Before she sailed for Europe in 1846 some of her essays appeared as *Papers on Literature and Art*, which assured the cordial welcome she received in English and French circles. America's first woman foreign correspondent, she reported on her travels for the *Tribune*; the "letters" were later published in *At Home and Abroad* (1856). Settling in Italy in 1847, she was caught up in the cause of the Italian revolutionists, led by Mazzini, and was secretly married to Giovanni Angelo, Marchese Ossoli. Following the suppression of the republic she sailed for America with her husband and infant son, Angelo. They perished in a shipwreck off Fire Island, and with them was lost her manuscript history of the revolution.

**Fuller, Melville Weston** (b. Feb. 11, 1833, Augusta, Maine, U.S.—d. July 4, 1910, Sorrento, Maine), eighth chief justice of the Supreme Court of the United States (1888-1910) whose amiability, impartiality, and rare administrative skill enabled him to manage court conferences efficiently and to resolve or forestall serious disputes among the justices whom he superintended. Justices Oliver Wendell Holmes and Samuel F. Miller, two outstanding members of the Fuller court, called him the best presiding judge they had ever known.

Graduated from Bowdoin College, Brunswick, Maine (1853), Fuller attended Harvard Law School briefly, was a newspaperman in Augusta for a time, was admitted to the bar in 1855, and from 1856 practiced law in Chicago. He was elected as a Democrat to the Illinois Constitutional Convention of 1861

and to the State House of Representatives in 1862.

Prominent at the Chicago bar but unknown nationally, Fuller was appointed chief justice by Pres. Grover Cleveland in 1888. He successfully administered a court that comprised

Melville Weston Fuller, 1902

By courtesy of the Library of Congress, Washington, D C

such justices as Holmes, Miller, Stephen J. Field, Joseph P. Bradley, and John Marshall Harlan, all of whom overshadowed him in either intelligence or forcefulness. He wrote two important opinions, both in 1895: *U.S. v. E.C. Knight Co.*, in which he construed the Sherman Anti-Trust Act of 1890 so narrowly as to prevent its application to almost any business except transportation; and *Pollock v. Farmers' Loan and Trust Co.*, in which he declared the federal income tax law of 1894 unconstitutional.

While serving as chief justice, Fuller also was an arbitrator of the Venezuelan boundary dispute between that nation and Great Britain (1897-99), and was a member of the Hague Court of International Arbitration (1900-10). A biography, *Melville Weston Fuller* (1950), was written by Willard L. King.

**Fuller, R(ichard) Buckminster** (b. July 12, 1895, Milton, Mass., U.S.—d. July 1, 1983, Los Angeles), U.S. engineer and architect who developed the geodesic dome, the only large dome that can be set directly on the ground

R. Buckminster Fuller shown with a geodesic dome constructed as the U.S. pavilion at the American Exchange Exhibit, Moscow, 1959

R. Buckminster Fuller

as a complete structure, and the only practical kind of building that has no limiting dimensions (i.e., beyond which the structural strength must be insufficient). Among the most noteworthy geodesic domes is the United States pavilion for Expo 67 in Montreal. Also a poet and a philosopher, he was noted for unorthodox ideas on global issues.

*Life*. Fuller was descended from a long line of New England Nonconformists, the most

famous of whom was his great-aunt, Margaret Fuller, the critic, teacher, woman of letters and cofounder of *The Dial*, organ of the Transcendentalist movement. Fuller was twice expelled from Harvard University and never completed his formal education. He saw service in the U.S. Navy during World War I as commander of a crash-boat flotilla. In 1917 he married Anne Hewlett, daughter of James Monroe Hewlett, a well-known architect and muralist. Hewlett had invented a modular construction system using a compressed fibre block, and after the war Fuller and Hewlett formed a construction company that used this material (later known as Soundex, a Celotex product) in modules for house construction. In this operation Fuller himself supervised the erection of several hundred houses.

The construction company encountered financial difficulties in 1927, and Fuller, a minority stockholder, was forced out. He found himself stranded in Chicago, without income, alienated, dismayed, confused. At this point in his life, Fuller resolved to devote his remaining years to a nonprofit search for design patterns that could maximize the social uses of the world's energy resources and evolving industrial complex. The inventions, discoveries, and economic strategies that followed were interim factors related to that end.

In 1927, in the course of the development of his comprehensive strategy, he invented and demonstrated a factory-assembled, air-deliverable house, later called the Dymaxion house, which had its own utilities. He designed (1928) and manufactured (1933) the first prototype of his three-wheeled omnidirectional vehicle, the Dymaxion car. The first streamlined car, it could cross open fields like a jeep, accelerate to 120 miles (190 km) per hour, make a 180° turn in its own length, carry 12 passengers, and average 28 miles per gallon (12 km per litre) of gasoline. In 1943, at the request of industrialist Henry Kaiser, Fuller developed a new version of the Dymaxion car that was planned to be powered by three separate air-cooled engines, each coupled to its own wheel by a variable fluid drive. The projected 1943 Dymaxion, like its predecessor, was never commercially produced.

Assuming that there is in nature a vectorial, or directionally oriented, system of forces that provides maximum strength with minimum structures, as is the case in the nested tetrahedron lattices of organic compounds and of metals, Fuller developed a vectorial system of geometry that he called "Energetic-Synergetic geometry." The basic unit of this system is the tetrahedron (a pyramid shape with four sides, including the base), which, in combination with octahedrons (eight-sided shapes), forms the most economic space-filling structures. The architectural consequence of the use of this geometry by Fuller was the geodesic dome, a frame the total strength of which increases in logarithmic ratio to its size. Many thousands of geodesic domes have been erected in various parts of the world, the most publicized of which was the United States exhibition dome at Expo 67 in Montreal. One houses the tropical exhibit area of a St. Louis botanical garden; another, the Union Tank Car Company's dome, was built in 1958 in Baton Rouge, La. This dome, at the time of its construction the largest clear-span structure in existence, is 384 feet (117 m) in diameter and 116 feet (35 m) in height.

Other inventions and developments by Fuller included a system of cartography that presents all the land areas of the world without significant distortion; die-stamped prefabricated bathrooms; tetrahedral floating cities; underwater geodesic-domed farms; and expendable paper domes. Fuller did not regard himself as an inventor or an architect, however.

All of his developments, in his view, were accidental or interim incidents in a strategy that aimed at a radical solution of world problems by finding the means to do more with less.

Comprehensive and anticipatory design initiative alone, he held—exclusive of politics and political theory—can solve the problems of human shelter, nutrition, transportation, and pollution; and it can solve these with a fraction of the materials now inefficiently used. Moreover, energy, ever more available, directed by cumulative information stored in computers, is capable of synthesizing raw materials, of machining and packaging commodities, and of supplying the physical needs of the total global population.

Fuller was a research professor at Southern Illinois University (Carbondale) from 1959 to 1968. In 1968 he was named university professor, in 1972 distinguished university professor, and in 1975 university professor emeritus. Queen Elizabeth II awarded Fuller the Royal Gold Medal for Architecture. He also received the 1968 Gold Medal Award of the National Institute of Arts and Letters.

*Assessment.* Fuller—architect, engineer, inventor, philosopher, author, cartographer, geometrician, futurist, teacher, and poet—established a reputation as one of the most original thinkers of the second half of the 20th century. He conceived of man as a passenger in a cosmic spaceship—a passenger whose only wealth consists in energy and information. Energy has two phases—associative (as atomic and molecule structures) and dissociative (as radiation)—and, according to the first law of thermodynamics, the energy of the universe cannot be decreased. Information, on the other hand, is negatively entropic; as knowledge, technology, "know-how," it constantly increases. Research engenders research, and each technological advance multiplies the productive wealth of the world community. Consequently, "Spaceship Earth" is a regenerative system whose energy is progressively turned to human advantage and whose wealth increases by geometric increments.

Fuller's book *Nine Chains to the Moon* (1938) is an outline of his general technological strategy for maximizing the social applications of energy resources. He further developed this and other themes in such works as *No More Secondhand God* (1962), *Utopia or Oblivion* (1969), *Operating Manual for Spaceship Earth* (1969), *Earth, Inc.* (1973), and *Critical Path* (1981). (R.W.M./Ed.)

**BIBLIOGRAPHY.** Appraisals of Fuller's life and work include Robert W. Marks, *The Dymaxion World of Buckminster Fuller* (1960, reissued 1973); John McHale, *R. Buckminster Fuller* (1962); Sidney Rosen, *Wizard of the Dome* (1969); Hugh Kenner, *Bucky* (1973); Donald W. Robertson, *Mind's Eye of Richard Buckminster Fuller* (1974, reprinted 1983); Alden Hatch, *Buckminster Fuller: At Home in the Universe* (1974); Amy C. Edmondson, *A Fuller Explanation: The Synergetic Geometry of R. Buckminster Fuller* (1987); Lloyd Steven Seiden, *Buckminster Fuller's Universe* (1989); and Martin Pawley, *Buckminster Fuller* (1990).

**Fuller, Roy**, in full ROY BROADBENT FULLER (b. Feb. 11, 1912, Failsworth, Lancashire, Eng.—d. Sept. 27, 1991, London), British poet and novelist, best known for his concise and observant verse chronicling the daily routines of home and office. Fuller's first volume of poetry appeared in 1939. *New and Collected Poems, 1934–84* (1985) is an authoritative collection; *Available for Dreams* (1989) and *Last Poems* (1993) contain his last verse. Fuller's novels include *Image of a Society* (1956), *The Ruined Boys* (1959), and *My Child, My Sister* (1965). His memoirs were published in four volumes (1980–91). He was made a Commander of the Order of the British Empire in 1970.

**fullerene**, any of a series of hollow carbon molecules that form either a closed cage

("buckyballs") or a cylinder (carbon "nanotubes"). The first fullerene was discovered in 1985 by Sir Harold W. Kroto of the United Kingdom and by Richard E. Smalley and Robert F. Curl, Jr., of the United States. Using a laser to vaporize graphite rods in an atmosphere of helium gas, these chemists and their assistants obtained cage-like molecules composed of 60 carbon atoms (C<sub>60</sub>) joined together by single and double bonds to form a hollow sphere with 12 pentagonal and 20 hexagonal faces—a design that resembles a football, or soccer ball (see the figure). In 1996 the trio was awarded the Nobel Prize for their pioneering efforts. The C<sub>60</sub> molecule was named buckminsterfullerene (or, more simply, the buckyball) after the American architect R. Buckminster Fuller, whose geodesic dome is constructed on the same structural principles. The elongated cousins of buckyballs, carbon nanotubes, were identified in 1991 by Iijima Sumio of Japan.

Prior to the discovery of the fullerenes, only two well-defined allotropes of carbon were known—diamond (composed of a three-dimensional crystalline array of carbon atoms) and graphite (composed of stacked sheets of two-dimensional hexagonal arrays of carbon atoms). The fullerenes constitute a third form. Nanotubes in particular exhibit a wide range of novel mechanical and electronic properties. They are excellent conductors of heat and electricity, and they possess an astonishing tensile strength. Such properties hold the promise of exciting applications in electronics, structural materials, and medicine. Practical applications, however, will be realized only when accurate structural control has been achieved over the synthesis of these new materials.

*Buckminsterfullerenes.* During the period 1985–90 Kroto, working with colleagues at the University of Sussex, Brighton, Eng., detected chainlike molecules of carbon atoms in interstellar gas clouds and in the atmospheres of carbon-rich red giant stars. On a visit to Rice University, Houston, Texas, in 1984, Curl directed Kroto to a laser-supersonic cluster beam apparatus developed by Smalley that could vaporize any material into a plasma of atoms. Kroto realized that the technique might be used to simulate the atmosphere of carbon stars and so provide compelling evidence for his conjecture that the chains originated in stars. In a now-famous 11-day series of experiments conducted in September 1985 at Rice University by Kroto, Smalley, and Curl and their student coworkers, Smalley's apparatus was used to vaporize graphite. The study not only confirmed that carbon chains were produced but also showed, serendipitously, that a hitherto unknown carbon cluster containing 60 atoms formed spontaneously in relatively high abundance. The scientists concluded that the C<sub>60</sub> cluster must be a spheroidal closed cage in the form of a truncated icosahedron—a polygon with 60 vertices and 32 faces, 12 of which are pentagons and 20 hexagons. They chose the imaginative name buckminsterfullerene for the cluster in honour of the designer-inventor of the geodesic dome.

In 1990 physicists Donald R. Huffman of the United States and Wolfgang Krätschmer of Germany announced a simple technique for producing macroscopic quantities of fullerenes, using an electric arc between two graphite rods in a helium atmosphere to vaporize carbon. With fullerenes now available in workable amounts, research on these species expanded to a remarkable degree, and the field of fullerene chemistry was born.

The C<sub>60</sub> molecule undergoes a wide range of novel chemical reactions. It readily accepts and donates electrons, a behaviour that suggests possible applications in batteries and advanced electronic devices. Particularly im-

The structure of fullerenes  
Encyclopædia Britannica, Inc.

portant are crystalline compounds of C<sub>60</sub> with alkali metals and alkaline-earth metals; these compounds are the only molecular systems to exhibit superconductivity at relatively high temperatures above 19 K (equivalent to -254° C or -425° F). Also interesting in fullerene chemistry are the so-called endohedral species, in which a metal atom is physically trapped inside a fullerene cage.

**Carbon nanotubes.** In 1991 Iijima Sumio of NEC Corporation's Fundamental Research Laboratory, Tsukuba Science City, Japan, investigated material extracted from solids that grew on the tips of carbon electrodes after being discharged under C<sub>60</sub> formation conditions. Iijima found that the solids consisted of tiny tubes made up of numerous concentric "graphene" cylinders, each cylinder wall consisting of a sheet of carbon atoms arranged in hexagonal rings. The cylinders, called multi-walled carbon nanotubes (MWNTs), usually had closed-off ends and ranged from 2 to 10 micrometres (millionths of a metre) in length and 5 to 40 nanometres (billionths of a metre) in diameter. The ends were generally capped by fullerene domes. In 1996 a group led by Smalley produced single-walled nanotubes (SWNTs) in high purity by laser vaporization of carbon impregnated with cobalt and nickel. These nanotubes are essentially elongated fullerenes.

Individual carbon nanotubes may be metallic or semiconducting, depending on the helical orientation of the rows of hexagonal rings in the walls of the tubes. SWNTs exhibit ballistic transport, a highly efficient and fast conduction process in which electrons propagate rapidly along the axis of the tube. Owing to such remarkable properties, electrical conductors made of bundles of nanotubes should exhibit zero energy loss. Indeed, the electric current-carrying capacity of nanotubes is approximately four orders of magnitude higher than that of copper.

The Young's modulus of MWNTs (a measure of their elasticity, or ability to recover from stretching or compression) is estimated by researchers to be greater than that of carbon fibres by a factor of 5 to 10. MWNTs are capable of readily absorbing loads via a sequence

of reversible elastic deformations, such as buckling or kinking, in which the bonds between carbon atoms remain intact.

**Potential applications.** It is now known that the most stable form of a carbon aggregate, containing tens to several thousands of atoms, is a closed buckyball or nanotube. These structures have engendered much excitement, especially with regard to possible future applications, but so far such applications have been few and far between.

Nevertheless, nanotubes in particular may well bring about a revolution in materials science. For example, if SWNTs can be made in bundles of 100 billion, then a material will be produced that may approach the limits of tensile strength possible for any known material involving the chemical bond. In practice, no material approaches its theoretical "intrinsic strength," because of breakdowns brought on by the propagation of microscopic defects through the material. A bundle of nanotubes, however, may bypass this problem, as microscopic defects may anneal along the length of a particular tube and certainly should not propagate across the bundle—thus avoiding the problems that occur in conventional materials. Estimates of potential tensile strength vary, but it is predicted that a 1-m (39-inch) rod may reach 50 to 100 times the strength of steel at one-sixth the weight. The impact of such a material on civil engineering, building construction, aircraft, and automobiles would be spectacular. In order to realize this potential, however, new processes will have to be discovered that can produce long (more than 1 m), perfectly ordered bundles in which all 100 billion nanotubes preferably have the same diameter and atomic arrangement.

More realistically, carbon-nanotube composite materials exhibiting improved behaviour over standard carbon-fibre composites are likely in the near term. In addition, applications on a small scale should be feasible for medical purposes—for instance, the strength of individual nanotubes may prove useful in microsurgery or nanosurgery.

(H.W.K./D.R.M.W.)

**Fullerton**, city, Orange county, southern California, U.S. Laid out in 1887 and named for land developer George H. Fullerton, it became a citrus centre after the arrival of the railroad in 1888. Oil was discovered in the 1890s. Residential and industrial growth was considerable after World War II. The city's several schools of higher learning include California State University, Fullerton (1957). Inc. city, 1904. Pop. (2003 est.) 131,249.

**fulmar**, any of several species of gull-like oceanic birds in the family Procellariidae. The northern fulmar (*Fulmarus glacialis*) ranges from temperate to Arctic waters, and the southern fulmar (*F. glacialisoides*) from temperate to Antarctic waters. The much larger giant fulmar, or giant petrel (*Macronectes giganteus*), is 90 cm (3 feet) long and has a wingspan of more than 200 cm (6.5 feet). It nests around the Antarctic Circle. Fulmars eat almost anything; their natural foods are small fish, squid, and crustaceans, but they often take ships' garbage and will come ashore for carrion. They fly low over the waves of the open ocean, thus resembling their narrower-winged relatives, the shearwaters, in flight.

**Fulton**, city, seat (1825) of Callaway county, central Missouri, U.S. It lies 26 miles (42 km) northeast of Jefferson City. Laid out in 1825 and named Volney, it was renamed shortly thereafter for Robert Fulton, steamboat engineer and inventor. Fulton is the seat of Westminster College (1851), where on March 5, 1946, Sir Winston Churchill delivered his "Iron Curtain" speech. To commemorate the occasion, the college brought from London and reconstructed on its campus the 12th-century Church of St. Mary the Virgin, Alder-

manbury, redesigned by Sir Christopher Wren in the 17th century. Inc. 1859. Pop. (2003 est.) 12,315.

**Fulton, Robert** (b. Nov. 14, 1765, Lancaster county, Pennsylvania [U.S.]—d. Feb. 24, 1815, New York, N.Y.), American inventor, engineer, and artist who brought steamboating from the experimental stage to commercial success. He also designed a system of inland waterways, a submarine, and a steam warship. Fulton was the son of Irish immigrants. When their unproductive farm was lost by mortgage foreclosure in 1771, the family moved to Lancaster, where Fulton's father died in 1774 (not 1786 as is generally written). Having learned to read and write at home, Fulton was sent at age eight to a Quaker school; later he became an apprentice in a Philadelphia jewelry shop, where he specialized in the painting of miniature portraits on ivory for lockets and rings.

Fulton, detail of an oil painting by Benjamin West, 1806; in the collection of the New York State Historical Association, Cooperstown

By courtesy of the New York State Historical Association, Cooperstown

After settling his mother on a small farm in western Pennsylvania in 1786, Fulton went to Bath, Va., to recover from a severe cough. There the paintings by the young man—tall, graceful, and an engaging conversationalist—were admired by people who advised him to study in Europe. On returning to Philadelphia, Fulton applied himself to painting and the search for a sponsor. Local merchants, eager to raise the city's cultural level, financed his passage to London in 1787.

Although Fulton's reception in London was cordial, his paintings made little impression; they showed neither the style nor the promise required to provide him more than a precarious living. Meanwhile, he became acquainted with new inventions for propelling boats: a water jet ejected by a steam pump and a single, mechanical paddle. His own experiments led him to conclude that several revolving paddles at the stern would be most effective.

Beginning in 1794, however, having admitted defeat as a painter, Fulton turned his principal efforts toward canal engineering. His *Treatise on the Improvement of Canal Navigation*, in 1796, dealt with a complete system of inland-water transportation based on small canals extending throughout the countryside. He included details on inclined planes for raising boats—he did not favour locks—aqueducts for valley crossings, boats for specialized cargo, and bridge designs featuring bowstring beams to transmit only vertical loads to the piers. A few bridges were built to his design

in the British Isles, but his canal ideas were nowhere accepted.

Undaunted, he travelled in 1797 to Paris, where he proposed the idea of a submarine, the "Nautilus," to be used in France's war with Britain; it would creep under the hulls of British warships and leave a powder charge to be exploded later. The French government rejected the idea, however, as an atrocious and dishonourable way to fight. In 1800 he was able to build the "Nautilus" at his own expense; he conducted trials on the Seine and finally obtained government sanction for an attack, but wind and tide enabled two British ships to elude his slow vessel.

In 1801 Fulton met Robert R. Livingston, a member of the committee that drafted the U.S. Declaration of Independence. Before becoming minister to France, Livingston had obtained a 20-year monopoly of steamboat navigation within the state of New York. The two men decided to share the expense of building a steamboat in Paris using Fulton's design—a side paddlewheel, 66-foot- (20-metre-) long boat, with an eight-horsepower engine of French design. Although the engine broke the hull, they were encouraged by success with another hull. Fulton ordered parts for a 24-horsepower engine from Boulton and Watt for a boat on the Hudson, and Livingston obtained an extension on his monopoly of steamboat navigation.

Returning to London in 1804, Fulton advanced his ideas with the British government for submersible and low-lying craft that would carry explosives in an attack. Two raids against the French using his novel craft, however, were unsuccessful. In 1805, after Nelson's victory at Trafalgar, it was apparent that Britain was in control of the seas without the aid of Fulton's temperamental weapons. In the same year, the parts for his projected steamboat were ready for shipment to the United States, but Fulton spent a desperate year attempting to collect money he felt the British owed him.

Arriving in New York in December 1806, Fulton at once set to work supervising the construction of the steamboat that had been planned in Paris with Livingston. He also attempted to interest the U.S. government in a submarine, but his demonstration of it was a fiasco. By early August 1807 a 150-foot- (45-metre-) long "Steamboat," as Fulton called it, was ready for trials. Its single-cylinder condensing steam engine (24-inch bore and four-foot stroke) drove two 15-foot-diameter side paddlewheels; it consumed oak and pine fuel, which produced steam at a pressure of two to three pounds per square inch. The 150-mile (240-kilometre) trial run from New York to Albany required 32 hours (an average of almost 4.7 miles [7.6 kilometres] per hour), considerably better time than the four miles per hour required by the monopoly. The passage was epic because sailing sloops required four days for the same trip.

After building an enginehouse, raising the bulwark, and installing berths in the cabins of the now-renamed "North River Steamboat," Fulton began commercial trips in September. He made three round trips fortnightly between New York and Albany, carrying passengers and light freight. Problems, however, remained: the mechanical difficulties, for example, and the jealous sloopboatmen, who through "inadvertence" would ram the unprotected paddlewheels of their new rivals. During the first winter season he stiffened and widened the hull, replaced the cast-iron crankshaft with a forging, litted guards over the wheels, and improved passenger accommodations. These modifications made it a different boat, which was registered in 1808 as the "North River Steamboat of Clermont," soon reduced to "Clermont" by the press.

In 1808 Fulton married his partner's niece, Harriet Livingston, by whom he had a son and three daughters.

In 1811 the Fulton-designed, Pittsburgh-built "New Orleans" was sent south to validate the Livingston-Fulton steamboat monopoly of the New Orleans Territory. The trip was slow and perilous, river conditions being desperate because of America's first recorded, and also largest, earthquake, which had destroyed New Madrid just below the confluence of the Ohio and Mississippi rivers. Fulton's low-powered vessel remained at New Orleans, for it could go no farther upstream than Natchez. He built three boats for Western rivers that were based at New Orleans, but none could conquer the passage to Pittsburgh.

Fulton was a member of the 1812 commission that recommended building the Erie Canal. With the English blockade the same year, he insisted that a mobile floating gun platform be built—the world's first steam warship—to protect New York Harbor against the British fleet. The "Demologos," or "Fulton," as the ship was alternately called, incorporated new and novel ideas: two parallel hulls, with paddlewheel between; the steam engine in one hull, and boilers and stacks in the other. It weighed 2,745 displacement tons and measured 156 feet (48 metres) in length; a slow vessel, its speed did not exceed 6 knots (6 nautical miles, or 11 kilometres, per hour). Launched in October 1814, the heavily gunned and armoured steamship underwent successful sea trials but was never used in battle; when peace came in December, it was transferred to the Brooklyn Navy Yard, where it was destroyed by an accidental explosion in 1829.

By 1810 three of Fulton's boats served the Hudson and Raritan rivers. His steamboats also replaced the horse ferries that were used for heavily travelled river crossings in New York, Boston, and Philadelphia. He retained the typical broad double-ended hulls that needed no turning for the return passage. Manhattan's crosstown Fulton Street, named in 1816, was the principal thoroughfare connecting the two river terminals.

Fulton spent much of his wealth in litigations involving the pirating of patents relating to steamboats and in trying to suppress rival steamboat builders who found loopholes in the state-granted monopoly. His wealth was further depleted by his unsuccessful submarine projects, investments in paintings, and financial assistance to farmer kin and young artists. After testifying at a legal hearing in Trenton, early in 1815, he became chilled en route home to New York, where he died. His family made claims on the U.S. government for services rendered. A bill of \$100,000 for the relief of the heirs finally passed the Congress in 1846 but was reduced to \$76,300, with no interest.

A Hudson-Fulton Celebration in 1909 commemorated the success of the "North River Steamboat of Clermont" and the discovery in 1609 of the North River by the English navigator who was the first to sail upstream to Albany. A "Robert Fulton" commemorative stamp was issued in 1965, the bicentenary of his birth, and the two-story farmhouse, his birthplace, was acquired and restored by the Pennsylvania Historical and Museum Commission. (R.S.H.)

**BIBLIOGRAPHY.** J.T. Flexner, *Steamboats Come True* (1944), a scholarly study of the principal American steamboat protagonists—Fitch, Rumsey, Livingston, Stevens, and Fulton—is a sober evaluation that presents much material untouched by earlier biographers such as Fulton's close friend, C.D. Colden, *The Life of Robert Fulton* (1817); and his great-granddaughter A.C. Sutcliffe, *Robert Fulton and the "Clermont"* (1909), among others. H.W. Dickinson, *Robert Fulton, Engineer and Artist* (1913), deals with technical matters in an exemplary way.

**Fulvia** (d. 40 bc, Sicily, Greece), in Roman history, the wife of Mark Antony, and a participant in the struggle for power following the death of Julius Caesar.

Fulvia was the daughter of Marcus Fulvius Bambalio of Tusculum. She was first married to the demagogic politician Publius Clodius. Their daughter Claudia was subsequently the wife of Octavian (the future Augustus). In 52 bc Clodius was murdered by a political rival, Milo; and his body was carried to Rome and placed in the atrium of his house, where Fulvia made a show of her grief and displayed her husband's wounds to the people in order to inflame them against Milo and his party. The result was a brief period of public disorder and the temporary banishment of Milo.

Fulvia next married Caius Scribonius Curio, who died in Africa in 49 bc; and in 44 she married Mark Antony. She apparently was deeply in love with him and had great ambition for him. During the proscriptions of 43 bc, Fulvia was reported to have viewed with pleasure the heads of Rufus and Cicero, Antony's victims.

After Antony and Octavian had deprived Lepidus of his place in the Triumvirate and Antony was living with Cleopatra, Fulvia conspired with Antony's brother, Lucius Antonius, against Octavian. Perhaps out of jealousy, wanting to force Antony's return to Italy, Fulvia induced Lucius Antonius to rebel against Octavian without Antony's consent. During the winter of 41–40 bc, Lucius Antonius was besieged in Perugia and starved into surrender. Fulvia was allowed to escape unharmed and crossed over into Greece, where she met with the returning Antony at Athens. His extreme anger with her over her meddling is supposed to have caused her profound grief. Her death soon after came at an opportune time for Antony, because it made possible his marriage to Octavia's sister, Octavia, which cemented the reconciliation with Octavian that he had achieved upon his return to Italy.

**fulvic acid**, type of humic acid (*q.v.*) that is slightly polymerized and that produces the soils known as podsol and podsollic soil.

**Fumariaceae**, the fumitory, or bleeding-heart family, of the order Papaverales, comprising about 19 genera of herbaceous plants, some of them valuable ornamentals, many containing alkaloids. The fumitories include annuals, biennials, and perennials and are found mostly in the Northern Hemisphere.

The flowers are bisexual, with two small sepals and four petals that are arranged in two series. One or both of the outer petals is spurred or lobed, and the lower petals often have thickened tips. Each flower has one pistil and six stamens that are in two bundles of three each (except in the genus *Pteridophyllum*, which has four ungrouped stamens). The ovary is superior (positioned above the point of attachment of the other flower parts—sepals, petals, and stamens), and the carpels (segments of the ovary) are fused. Most species have deeply cut leaves. The fruit is a capsule.

The most widely grown ornamental of the family is the bleeding heart (*q.v.*; *Dicentra spectabilis*), a native of Japan. Other ornamentals are Dutchman's-breeches (*q.v.*; *D. cucullaria*), squirrel corn (*q.v.*; *D. canadensis*), North American eastern and western bleeding hearts (*D. eximia* and *D. formosa*), fumitory (*q.v.*; *Fumaria officinalis*), Allegheny vine (*Adlumia fungosa*), and the various European and North American members of the genus *Corydalis* (*q.v.*).

*Pteridophyllum racemosum* is a perennial from the mountains of Japan that has distinctive fernlike leaves and 25-centimetre- (10-inch-) long sprays of white flowers.

**fumaric acid**, also called TRANS-BUTENEDIC ACID, organic compound related to malic acid (*q.v.*).

**fumarole**, any vent from which volcanic vapours issue. Water vapour is the dominant constituent of such vapours, but acid gases, such as carbon dioxide and hydrogen sulfide, also characteristically occur.

Fumaroles, like geysers, are manifestations of hot springs, which disperse groundwater from the upper parts of the Earth's crust after it has been heated by magma (molten silicate material) and magmatic gases. As magma begins to solidify to form crystalline rock, its gases become concentrated under ever-increasing pressure in the residual, uncrystallized liquid. When the pressure becomes sufficiently high, this liquid, consisting chiefly of hot water and containing gases and minerals in solution, is forced into cracks in the surrounding solid rock. A fumarole is formed if a crack extends upward and opens at the surface. The intimate connection between fumaroles and simple hot springs is obvious in areas where a strong contrast between dry and wet seasons exists. During the dry season, hot springs are transformed into fumaroles, which become hot springs again during periods of heavy precipitation. See also geyser; hot spring.

**fumigant**, any volatile, poisonous substance used to kill insects, nematodes, and other animals or plants that damage stored foods or seeds, human dwellings, clothing, and nursery stock. Soil fumigants are sprayed or spread over an area to be cultivated and are worked into the soil to control disease-causing fungi, nematodes, and weeds.

Fumigants with a high vapour pressure, such as methyl bromide, ethylene oxide, hydrogen cyanide, and hydrogen phosphide, penetrate quickly and are used to treat sealed storage areas or materials enclosed in gasproof sheets. Low-pressure compounds such as ethylene dibromide and ethylene dichloride diffuse more slowly; they are used to treat more open storage areas and as soil fumigants. Common fumigants used to treat stored products or nursery stock include hydrogen cyanide, naphthalene, nicotine, and methyl bromide. Soil fumigants commonly used as nematocides are methyl bromide, dichloropropane, propylene oxide, dibromochloropropane, organophosphate insecticides, and chloropicrin. Because these substances may kill other soil organisms that ordinarily control nematodes by predation or infection, serious nematode infestations may follow fumigation.

Other compounds used as fumigants include acrylonitrile, carbon disulfide, ethylene, paradichlorobenzene, sulfur dioxide, and sulfur fluoride. Fumigants are poisonous to warm-blooded animals, including humans; they should be applied only by trained persons using proper equipment.

**fumitory**, any of several plant species of the genus *Fumaria* of the fumitory family (Fumariaceae) but, most commonly, *F. officinalis*.

Fumitory (*Fumaria officinalis*)

G.E. Hyde—EB Inc

*nalis*, a 90-centimetre- (3-foot-) tall, climbing annual plant with lacy leaves and spikelike sprays of white or pinkish tubular flowers. *Fumaria officinalis*, native to Europe and Asia, now grows wild in parts of North America, having escaped from gardens. Once regarded as a medicinal herb, it was also used in Great Britain, boiled in water or milk, as a cosmetic.

Climbing fumitory (*Adlumia fungosa*), also known as Allegheny vine, or mountain fringe, is a sprawling, herbaceous biennial that coils its long leafstalks around supports. It reaches

Porto do Funchal, Ilha da Madeira, Madeira Islands

V. Phillips—Shostal/EB Inc

3.5 m (11.5 feet) in height and has clusters of white or pinkish tubular flowers borne among delicately cut leaves. The only species of its genus, it is native to moist woodlands and freshly burned areas from eastern to central North America to Japan.

**Funabashi**, city, Chiba *ken* (prefecture), Honshu, Japan, situated on the inner coast of Tokyo Bay. It was formed by the amalgamation of the post town of Funabashi with the fishing village of Katsushika in 1937. With the construction of a major railway along the east coast of the bay in 1894, the city lost its importance as a road transport centre. Army installations erected in the early 20th century contributed to Funabashi's recovery, however, and the later construction of two other railway lines to Tokyo made possible its growth as a residential suburb. After World War II parts of the coast were reclaimed and a seaside industrial zone of iron, steel, and petrochemical plants was developed. The northern part of the city is an agricultural zone producing for the Tokyo market. Pop. (2000 prelim.) 550,079.

**Funafuti Atoll**, coral atoll, site of Fongafale village, capital of Tuvalu, in the west-central Pacific Ocean. The atoll comprises some 30 islets, with a total land area of 0.9 square mile (2.4 square km), strung around a lagoon (13.5 by 10 miles [21.7 by 16.1 km]) that affords good anchorage. A U.S. military base was established there in 1943. Despite the low fertility of its sandy soil, the atoll produces copra for export. Fongafale, the chief village, has a hotel, a hospital, and an airstrip. Pop. (2000 est.) 4,590.

**Funan**, ancient Hindu state in Cambodia that arose in the 1st century AD and was incorporated into the state of Chenla in the 6th century. Funan (a Chinese transcription of *pnom*, "mountain") was the first important Hinduized kingdom in southeast Asia. It covered portions of what are now Vietnam, Thailand, and Cambodia. Funan had trade relations with India as well as China, to whose emperor the people of Funan sent tribute between the 3rd and 6th centuries. Archaeological evidence shows that Funan was influenced markedly by Indian cultures.

**Funchal**, city, capital, and *concelho* (township) of Funchal *distrito* ("district"), Portugal, which district comprises the Madeira Islands (*q.v.*) in the North Atlantic. Funchal lies on the southern coast of the Ilha da Madeira.

Founded in 1421 by the Portuguese navigator João Gonçalves Zarco, the city was briefly under Spanish (1580–1640) and British (1801, 1807–14) control. It is now the headquarters

of Madeiran industry, commerce, and communications and is the site of a relay station in the Atlantic submarine cable system. The older part of the city focuses on the Sé cathedral (1485–1514) and has steep, narrow cobblestone streets. The buildings are generally whitewashed and are surrounded by gardens of tropical flowers; they line the curving shore of the Port of Funchal and spread inland on the lower slopes of an amphitheatre of mountains that reach 4,000 feet (1,200 m) in elevation. Stone walls support sloping terraces on which there is year-round cultivation.

Tourism, based on the scenery and the mild year-round climate, is a major economic factor. Exports from Funchal include the famous Madeiran wines, wickerwork, embroidery, fruit, fish, and dairy products. Economically significant industries include sugar milling, cabinetmaking, and distilling. Since 1960 Funchal's harbour and cargo-handling facilities have been enlarged and modernized from time to time; it is now an important regional port of call and bunkering facility. The city also has an international airport. Pop. (2001 prelim.) city, 102,521; (1992 est.) district, 253,000.

**function**, in mathematics, an expression, rule, or law that defines a relationship between one variable (the independent variable) and another variable (the dependent variable). In its most general usage in mathematics the word *function* refers to any correspondence between two classes. For most functions the variables range over classes of numbers. For example, the formula  $A = \pi r^2$  gives for each positive real number  $r$  the area of the circle with radius  $r$ . The expressions  $a + bx + cx^2$  and  $a_0 + a_1x + \dots + a_nx^n$  are polynomial functions of  $x$  when the coefficients  $a$ ,  $b$ ,  $c$ ,  $a_0$ ,  $a_1$ ,  $\dots$ ,  $a_n$  are given. The short symbols  $f(x)$ ,  $g(x)$ ,  $P(x)$ ,  $\dots$  are often used for functions of the independent variable  $x$ , either for the sake of abbreviation, or because the nature of the function is unknown or unspecified. The quotient of two polynomials  $P(x)/Q(x)$  is called a rational function. A polynomial is regarded as a special case of a rational function. The trigonometric functions  $\sin x$ ,  $\cos x$ ,  $\tan x$  and others, where  $x$  is the measure of

an angle, are defined geometrically in elementary trigonometry; for practical purposes their values are given in tables. Many functions of practical importance are defined only by means of tables, as in statistics. For example, the death rate in each year over a period of years is given in mortality tables used by life insurance companies.

Inverse functions are obtained from given functions by interchanging the roles of the independent and dependent variables. Thus, if the given function is written  $y = 2x$ , the inverse function would be written  $x = y/2$ . The two functions determine the same correspondence between the two variables. The exponential function  $y = 10^x$  gives a value of  $y$  for each real value of  $x$ . These values are not easily computed unless  $x$  is an integer. In this case the inverse function is written  $x = \log_{10} y$  and its values are given in tables of common logarithms.

Functions involving more than two variables occur frequently in applications of mathematics. For example, the formula  $A = \frac{1}{2}bh$  gives the area of a triangle in terms of its base  $b$  and altitude  $h$ .

*Functions of a complex variable.* The preceding examples dealt with real variables. Practical applications of functions of a complex variable are not so easy to illustrate, but are nevertheless very extensive. They occur, for example, in electrical engineering and aerodynamics. If the complex variable is represented in the form  $x = u + iv$ , where  $i$  is the imaginary unit, and  $u$  and  $v$  are real, it is possible to set  $f(x) = P(u, v) + iQ(u, v)$ , where for example  $P(u, v) = u^3 + v^2$ ,  $Q(u, v) = 3uv^3 - v$ .

*Geometric representation of functions.* Real-valued functions  $y = f(x)$  of one real variable may be given a geometric representation by means of the analytic geometry of René Descartes. The independent variable  $x$  is plotted along a number scale on a line called the  $x$ -axis, which is usually taken as horizontal, and the dependent variable  $y$  is plotted along a number scale on another line called the  $y$ -axis which is usually taken as vertical. The graph of the function consists of the points with coordinates  $(x, y)$  where  $y = f(x)$ . For example, the graph of a quadratic function  $y = a + bx + cx^2$  is a parabola, if  $c \neq 0$ . Some functions are given only by their graphs. Examples are the temperature, air pressure, and wind velocity as recorded by weather bureau instruments.

*Methods of defining a function.* A function may be defined by means of a power series. For example, the series

$$e^x = 1 + x + \frac{x^2}{2!} + \cdots + \frac{x^n}{n!} + \cdots$$

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} \cdots$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} \cdots$$

could be used to define these functions for all complex values of  $x$ . Other types of series and also definite products may be used when convenient. An important case is the series of Fourier, expressing a function in terms of sines and cosines,

$$f(x) = a_0 + a_1 \cos x + a_2 \cos 2x + \cdots \\ + b_1 \sin x + b_2 \sin 2x + \cdots$$

Such representations are of great importance in physics, in the study of wave motion and other oscillatory phenomena.

A function may be defined by the values of  $y$  satisfying an equation involving  $x$  and  $y$ . For example,  $y = \sqrt{x}$  is defined by the polynomial equation  $y^2 - x = 0$ . Every function  $y = f(x)$

defined by a polynomial equation between  $x$  and  $y$ , such as  $x^2y^3 - x^3y + x = 1$ , is called an algebraic function. Transcendental functions may be defined by other types of equations. For example, if the function  $\sin x$  is known, the function  $y = \cos x$  is defined by the equation  $\sin^2 x + y^2 = 1$  if we take the solution  $y$  that has the value  $+1$  when  $x = 0$ . The solution of  $x = e^y$  for  $y$  gives the inverse function  $y = \log_e x$ , which is a multiple-valued function having infinitely many values when  $x$  is complex. Sometimes functions are most conveniently defined by means of differential equations. For example,  $y = \sin x$  is the solution of the differential equation  $d^2y/dx^2 + y = 0$  having  $y = 0$ ,  $dy/dx = 1$  when  $x = 0$ ;  $y = \cos x$  is the solution of the same equation having  $y = 1$ ,  $dy/dx = 0$  when  $x = 0$ .

**functional group**, any of numerous combinations of atoms that form parts of chemical molecules, that undergo characteristic reactions themselves, and that in many cases influence the reactivity of the remainder of the molecule. In organic chemistry the concept of functional groups is useful as a basis for classification of large numbers of compounds according to their reactions.

Some of the common functional groups are hydroxyl, present in alcohols and phenols; carbonyl, present in carboxylic acids; carbonyl, present in aldehydes, ketones, and quinones; and nitro, present in certain organic nitrogen compounds.

**Functionalism**, in architecture, the doctrine that the form of a building should be determined by practical considerations such as use, material, and structure, as distinct from the attitude that plan and structure must conform to a preconceived picture in the designer's mind.

Although Functionalism is most closely associated with modern architecture (and to some extent with modern furniture), it is by no means an exclusively modern conception. Apart from the fact that even the most fanciful architecture has practical functions to fulfill, there have been times in the past when functional considerations have been unusually dominant, and the artistic character of the buildings of such times has been directly derived from the way the challenge of function has been met. Historical European examples include the military architecture of the early Middle Ages, certain periods of Gothic ecclesiastical architecture, and much of the industrial and commercial architecture of the 19th century. The expression "the functional tradition" is applied to this emphasis on functionalism, which appears and reappears throughout the history of architecture independently of changes in style.

The Functionalist creed, however, is especially associated with the modern style of architecture, which developed during the second quarter of the 20th century as a result of changes in building technique, new types of buildings required, and changing cultural and aesthetic ideals. In fact, as architects began to show discontent with the historical revivalism that had been paramount in the 19th and early 20th centuries, a type of architecture based on the clear outward expression of the function of the building was bound to develop. The slogan "form follows function," coined in the 1880s by one of the pioneers of modern architectural design, Louis Sullivan, and the dictum of the architect Le Corbusier "a house is a machine for living," which dates from 1920, both state the idea uncompromisingly. The latter assertion, however, although typical of the polemical statements made in the 1920s, when the battle for a more functional approach to architecture was being most strenuously fought, was not meant literally, as other statements of Le Corbusier indicate. The supporters of Functionalism in architecture have on occasion asserted that good architecture is

automatically produced by the fulfillment of practical needs; yet in this fulfillment there remain many alternatives among which the architect must choose, and such a choice may determine the difference between good and bad architecture.

Le Corbusier's and similar statements do, nevertheless, reflect the insistence of the modern architect that the process of design begins with an analysis of the building's function and of the best technical means of meeting it and that aesthetic character, instead of being superimposed, emerges as a part of the same process. For this reason, the emphasis on Functionalism in modern architecture implies a reunion of architecture and engineering, which had become separated in the 19th century.

**functionalism**, in linguistics, the approach to language study that is concerned with the functions performed by language, primarily in terms of cognition (relating information), expression (indicating mood), and conation (exerting influence). Especially associated with the Prague school of linguists prominent since the 1930s, the approach centres on how elements in various languages accomplish these functions, both grammatically and phonologically. Some linguists have applied the findings to work on stylistics and literary criticism.

**functionalism**, in social sciences, theory based on the premise that all aspects of a society—institutions, roles, norms, etc.—serve a purpose and that all are indispensable for the long-term survival of the society. The approach gained prominence in the works of 19th-century sociologists, particularly those who viewed societies as organisms. The French sociologist Émile Durkheim argued that it was necessary to understand the "needs" of the social organism to which social phenomena correspond. Other writers have used the concept of function to mean the interrelationships of parts within a system, the adaptive aspect of a phenomenon, or its observable consequences. In sociology, functionalism met the need for a method of analysis; in anthropology it provided an alternative to evolutionary theory and trait-diffusion analysis.

A social system is assumed to have a functional unity in which all parts of the system work together with some degree of internal consistency. Functionalism also postulates that all cultural or social phenomena have a positive function and that all are indispensable. Distinctions have been made between manifest functions, those consequences intended and recognized by participants in the system, and latent functions, which are neither intended nor recognized.

The British anthropologist A.R. Radcliffe-Brown explored the theoretical implications of functionalism as a relationship between a social institution and the "necessary conditions of existence" of a social system. He saw the function of a unit as the contribution it makes to the maintenance of a social structure—i.e., the set of relationships among social units.

In an attempt to develop a more dynamic analysis of social systems, the American sociologist Talcott Parsons introduced a structural-functional approach that employs the concept of function as a link between relatively stable structural categories. Any process or set of conditions that does not contribute to the maintenance or development of the system is said to be dysfunctional. In particular, there is a focus on the conditions of stability, integration, and effectiveness of the system.

**functionalism**, in psychology, a broad school of thought originating in the U.S. during the late 19th century that attempted to counter the German school of structuralism led by Edward B. Titchener. Functionalists, including psychologists William James and James

Rowland Angell, and philosophers George H. Mead, Archibald L. Moore, and John Dewey, stressed the importance of empirical, rational thought over an experimental, trial-and-error philosophy. The group was concerned more with the capability of the mind than with the process of thought. The movement was thus interested primarily in the practical applications of research.

The union between theory and application reached its zenith with John Dewey's development of a laboratory school at the University of Chicago in 1896 and the publication of his keystone article, "The Reflex Arc Concept in Psychology" (1896), which attacked the philosophy of atomism and the concept of elementarism, including the behavioral theory of stimulus and response. The work of John Dewey and his associates stimulated the progressive-school movement, which attempted to apply functionalist principles to education. In the early and mid-20th century, an offshoot theory emerged: the transactional theory of perception, the central thesis of which is that learning is the key to perceiving.

Although functionalism has never become a formal, prescriptive school, it has served as a historic link in the philosophical evolution linking the structuralist's concern with the anatomy of the mind to the concentration on the functions of the mind and, later, to the development and growth of behaviourism.

**fundamental interaction**, in physics, any of the four basic forces—gravitational, electromagnetic, strong, and weak. All the known forces of nature can be traced to these fundamental interactions. Gravitation and electromagnetism were recognized long before the discovery of the strong and weak forces because their effects on ordinary objects are readily observed. The gravitational force acts between all objects having mass; it causes apples to fall from trees and determines the orbits of the planets around the Sun. The electromagnetic force is responsible for the repulsion of like and attraction of unlike electric charges; it explains the chemical behaviour of atoms and the properties of light. The strong and weak forces were discovered by physicists in the 20th century when they finally probed into the core of the atom. The strong interaction binds the protons and neutrons of the atomic nucleus together in spite of the intense repulsion of the positively charged protons for each other. The weak interaction manifests itself in certain forms of radioactive decay and in reactions between the lightest subatomic particles (*i.e.*, electrons, muons, and their associated neutrinos).

The four forces are often described according to their relative strengths. The strong force is regarded as the most powerful force in nature. It is followed in descending order by the electromagnetic, weak, and gravitational. Despite its strength, the strong force does not manifest itself in the macroscopic universe because of its extremely limited range. It is confined to an operating distance of about  $10^{-13}$  cm—about the diameter of a proton. When two particles that are sensitive to the strong force pass within this distance, the probability that they will interact is high. The range of the weak force is shorter. Particles that are affected by this force must pass within  $10^{-17}$  cm of one another to interact, and the probability that they will do so is low even at that distance. By contrast, the gravitational and electromagnetic forces operate, at least in theory, at an infinite range. That is to say, gravity acts between all objects of the universe, no matter how far apart they are, and an electromagnetic wave, such as the light from a distant star, travels undiminished through space until it encounters some particle capable of absorbing it.

For years physicists have sought to show that the four basic forces are simply different manifestations of the same fundamental force. The

most successful attempt at such a unification is the electroweak theory, proposed during the late 1960s by Steven Weinberg, Abdus Salam, and Sheldon Lee Glashow. This theory, which incorporates quantum electrodynamics (the quantum field theory of electromagnetism), treats the electromagnetic and weak forces in a unified manner, postulating the existence of a more basic electroweak force that is transmitted by four gauge bosons. One of these is the photon of electromagnetism, while the other three are associated with the weak force—the electrically charged  $W^+$  and  $W^-$  and the neutral  $Z^0$  particles. Unlike the photon, these weak gauge bosons are massive.

In the 1970s investigators formulated a theory for the strong force that is similar in structure to quantum electrodynamics. According to this theory, the strong force is transmitted by gauge bosons dubbed gluons. Like photons, gluons are massless and travel at the speed of light. But they differ from photons in one important respect: they carry what is called "colour" charge, a property analogous to electric charge. Gluons are able to interact together because of colour charge, which at the same time limits their range.

Investigators are seeking to devise comprehensive theories that will unify all four basic forces of nature. So far, however, gravity remains beyond attempts at such unified field theories.

**Fundamental Laws** (1906), laws promulgated by the Russian emperor Nicholas II, ostensibly to carry out the governmental reforms promised in his earlier October Manifesto (*q.v.*).

**fundamentalism**, conservative movement in American Protestantism arising out of the millenarian movement of the 19th century and emphasizing as fundamental to Christianity the literal interpretation and absolute inerrancy of the Scriptures, the imminent and physical Second Coming of Jesus Christ, the Virgin Birth, Resurrection, and Atonement. Fundamentalism came into its own in the early 20th century in opposition to modernist tendencies in American religious and secular life. In the late 20th century the movement was represented by numerous church bodies, educational institutions, and special-interest organizations. *See also* evangelical church.

*Origins.* The roots of fundamentalism are found in the history of the American millenarian movement. In the 1830s and '40s, much excitement was generated in the United States by expectations of the Second Advent of Christ and an ensuing thousand years of peace ("the millennium"). The initially scattered interest in the subject was concentrated and built into a movement largely through the Niagara Bible Conference. Initiated by James Inglis, a New York City Baptist minister, shortly before his death in 1872, the conference continued under James H. Brookes (1830–97), a St. Louis Presbyterian minister and editor of the influential millenarian periodical *The Truth*. Other early millenarian leaders included George C. Needham, a Baptist evangelist (1840–1902); William J. Erdman (1834–1923), a Presbyterian minister noted for his skill as a biblical expositor; and William R. Nicholson (1822–1901), who left the Episcopal church in 1873 and became a bishop in the Reformed Episcopal denomination.

Toward the close of the century, the movement attracted leaders such as the prominent Boston Baptist minister Adoniram J. Gordon (1836–95) and Maurice Baldwin (1836–1904), bishop of Huron in the Church of Canada. The group held annual summer conferences, which generally met at Niagara-on-the-Lake, Ontario, until 1899. The millenarians associated with the Niagara Conference also sponsored public conferences in major cities beginning in 1878, such as the Bible and Prophetic Conference in New York City.

*Development of fundamentalist views.* The millenarian movement began to grow within America when confidence in America's destiny first began to wane among some Protestant leaders, faced as they were with labour unrest, social discontent, and the rising tide of Roman Catholic immigration. During the late 1880s and '90s the challenges posed by the rise of liberal Biblical criticism also won many converts to the millenarian movement.

As the century drew to a close, the Protestant evangelist Dwight L. Moody (1837–99) provided in his Northfield conferences an influential platform for millenarian expression. Millenarians supported foreign-missions work and influenced the surge of missionary zeal that was eventually institutionalized as the Student Volunteer Movement. Also, they found within the Princeton Theological Seminary at Princeton, N.J., a group of scholars interested in defending the authority and inspiration of the Bible.

Millenarians invited the Princeton professors to their conferences and adopted their arguments in defense of the Bible. Virtually none of the Princeton faculty adopted millenarianism, and some opposed it strongly, but both parties appreciated each other's support on the issue of biblical authority.

The high point of millenarian influence upon the conservative tradition within evangelical Protestantism occurred when millenarians cooperated with other defenders of the inerrancy of the Bible in founding the American Bible League in 1902 and in writing a series of 12 pamphlets entitled *The Fundamentals*. The pamphlets attacked the current theories of biblical criticism and reasserted the authority of the Bible, using the arguments developed at the Princeton Theological Seminary. The series was a summary of the previous generation's attempt to oppose biblical criticism and modernism through argument.

Almost all the leaders who had founded the Niagara Conference had died by 1914. The new generation of leaders were not as firmly attached to their denominations as were their predecessors. And their defense of the millenarian cause was more militant and uncompromising. During the last years of the 19th century, disagreements over prophetic interpretation were expressed, but James H. Brookes held the dissident factions together. Within a few years of his death, however, the Niagara Conference was abandoned, and shortly thereafter a paper war broke out between the two leading millenarian periodicals, *Watchword and Truth* and *Our Hope*, that deeply divided the movement.

*The fundamentalist-modernist controversy.* At the end of World War I, the millenarians, alarmed by the growth of liberalism and disturbed over what they conceived to be social degeneracy, held a number of conferences in New York City and Philadelphia that were successful enough to encourage the formation of a larger and more comprehensive organization in 1919, the World's Christian Fundamentals Association. As a result of this conference, the millenarian movement changed its name without changing its basic character. Furthermore, the 1919 conference placed planks in a platform on which the millenarian-fundamentalist movement would stand for the next 30 years.

The leaders reiterated the creedal basis of the movement, called for the exorcism of modernism and all its associated demons (especially evolution), practically abandoned the universities and placed their faith in the more recently founded Bible institutes, denounced the unitive and cooperative spirit exemplified in the Federal Council of the Churches of Christ in America, and threatened schism if this type of spiritual decline persisted. In spite

of vigorous leadership, however, the association never prospered.

During the late 19th century, the liberal faction in the church had numbered only a few men, most of them professors in seminaries or universities. Their acceptance of higher criticism was viewed with apprehension by parishioners, the clergy, and officials of their denominations. Where legal machinery existed to examine the new teachings, as it did in the Presbyterian denomination, the verdict was given against the innovations of liberals.

Within a few decades, however, evidence for the new understanding of the Bible mounted and a new generation of seminarians had joined the liberal cause. By 1914, among the Episcopal, Methodist, Baptist, and Presbyterian denominations in the North, liberalism had gained many adherents. The battle to prevent the reception and spread of these new views had been lost. During the 1920s it only remained to be decided whether the liberals could be forced out of the denominations.

Not every Protestant denomination was affected by intellectual controversy during the 1920s, of course. In some, such as the Southern Baptist denomination, modernism had not yet become prominent. In others, such as the Methodist and Episcopal churches, modernism had gained many adherents; but the opposition did not become well enough organized to bring the issue to a focus.

Serious controversy did erupt, however, among the northern Baptists and the Presbyterians in the northern states. Within the Presbyterian church, conservatives had, with the help of the millenarians, imposed a set of essential doctrines upon the denomination in 1910, declaring the inerrant inspiration of the Bible, the Virgin Birth of Christ, and the Atonement (redemptive activity), Resurrection, and miracle-working power of Christ necessary to the Christian faith. In 1922, when a New York minister, Harry Emerson Fosdick, soon to become a leading modernist spokesman, protested the activities of millenarians in foreign-mission fields in a sermon entitled "Shall the Fundamentalists Win?" the conservatives and millenarians in the denomination were able to force Fosdick, who was a Baptist, out of his position as pastor of the First Presbyterian Church of New York City.

A withdrawal of the liberals had been the solution desired by millenarians and conservatives. To avoid a schism within the Presbyterian church in the United States, a Commission of Fifteen was appointed to work out a compromise. The report of the commission took the position that the Presbyterian denomination had traditionally tolerated a diversity of opinion and rejected the right of the General Assembly to determine which were the essential doctrines of the Christian faith. The report virtually destroyed the conservatives' position.

The focus of discord within the northern Baptist denomination was in their annual convention, which functioned much like the convention of a political party. Beginning in 1920, a group of Baptists calling themselves the National Federation of Fundamentalists began holding annual pre-convention conferences on Baptist fundamentals. Thus organized, they attempted to carry their views into the convention. When the tactics of the National Federation failed to make immediate progress, some of the more militant Baptist fundamentalists founded the Baptist Bible Union. Among the Baptists, however, as among the Presbyterians, divisions among the fundamentalists caused their defeat.

Displeasure with the teaching of evolution, as well as anxiety over the spread of biblical criticism, gained momentum in the 1920s. Fundamentalists, believing that the Bible could not

be reconciled with the view of the origin of life put forward by Charles Darwin, opposed evolution; but not every opponent of evolution was a fundamentalist. Antievolution crusaders lobbied for legislation to prevent the teaching of evolution in the public schools. Tennessee passed such a statute, which was challenged in the courts in 1925 at the instigation of the American Civil Liberties Union. John T. Scopes, a science teacher in the small town of Dayton, offered to serve as the defendant against the charge of having taught evolution. Two of the foremost public figures of that decade, William Jennings Bryan, a Presbyterian fundamentalist, and Clarence Darrow, a defense counsel in notable criminal trials, made headlines as the assistant prosecuting attorney and the defense attorney, respectively.

*Institutional development.* During the 1930s and 1940s, fundamentalists gradually withdrew from conflict and from the national spotlight. During this period the institutional structure of modern fundamentalism developed. Some fundamentalist Presbyterians and Baptists broke away from their denominations to form new churches, such as the Presbyterians, led by J. Gresham Machen, who in 1936 formed the Presbyterian Church in America, or the Baptists, who left the Northern Baptist Convention to establish the General Association of Regular Baptists. Some remained within congregations of the larger denominations. But most fundamentalists joined a congregation of one of the smaller sects that had remained faithful to the creed of biblical literalism and premillennialism, such as the Christian and Missionary Alliance, the Plymouth Brethren, and the Evangelical Free Church, or one of the many independent Bible churches and tabernacles that arose during that period.

Much of the structure of modern fundamentalism is provided by Bible institutes and Bible colleges. Many of these schools, such as the Moody Bible Institute in Chicago, Ill. or the Bible Institute of Los Angeles, Calif., in addition to teaching their students, publish periodicals, broadcast from their own radio stations, hold conferences, and maintain a staff of extension speakers. They operate very much like denominational headquarters, providing a bond between otherwise isolated congregations. In the arts and sciences the strongest bastion has long been Wheaton College, a scholarly college in a suburb of Chicago.

There is also a series of organizations for fundamentalists paralleling the professional and business organizations of American society. Doctors, scientists, athletes, social workers, historians, businessmen, nurses, students, and others may join groups designed especially for their interest or vocational area. Chapters of the Inter-Varsity Christian Fellowship and Campus Crusade for Christ exist on hundreds of university and college campuses to provide religious support similar to that provided by organizations of the major Protestant denominations and Roman Catholics. The American Scientific Affiliation holds meetings and publishes a journal in which the compatibility of science with the Bible and with a Christian worldview is emphasized.

Paralleling the ecumenical bodies of Protestantism are the American Council of Christian Churches (ACCC) founded in 1941 and the National Association of Evangelicals (NAE) founded in 1942. The ACCC was (until 1969) virtually the voice of one man, Carl McIntire, who spoke against larger ecumenical bodies, such as the National Council of Churches, and against the alleged dangers of communism. The NAE operates as a coordinating body for its members but implements no programs of its own.

The most significant influences upon the fundamentalist and evangelical churches in America since World War II have been the prosperity of the postwar decades, the religious revival of the 1950s, and the alleged threat of

communist subversion. The new public image of the fundamentalist during this period was perhaps best exemplified by the evangelist Billy Graham.

The issue of communism that preoccupied the American public during the 1950s closely resembled the traditional concerns of fundamentalism—namely, biblical criticism and evolution—which fundamentalists believed came from abroad, seemed to spread uncontrollably and subversively, and tended to undermine Christianity. The anticommunist activities of the mid-20th century virtually duplicated the history of the antievolution crusade of the 1920s. The evolution controversy itself resurfaced in the 1960s when creationists (those accepting literal interpretations of the biblical Creation account in Genesis), dismayed by the emphasis on evolutionary theory in biology textbooks, sought again to ban the teaching of evolution in the public schools. In the 1970s creationists campaigned for the mandatory teaching of Genesis whenever evolutionary theory was taught. This was followed by an attempt to mandate the teaching of so-called "creation science," or "scientific creationism," which presumed to present creationism and evolutionary theory as alternative scientific models. All of these movements were successfully challenged in the U.S. courts on constitutional grounds. The fundamentalist creationists gained some ground in conservative areas, and the issue generated a broader controversy concerning the rights of parents to determine what their children are taught. Also during this period the so-called Moral Majority, a fundamentalist citizens' organization under the leadership of Baptist minister Jerry Falwell of Virginia, crusaded against legalized abortion, homosexual rights, and the women's Equal Rights Amendment and crusaded for school prayer, increased defense spending, and a strong anticommunist foreign policy.

Fundamentalist beliefs have not changed significantly since the time of the Niagara conferences. The greatest theological excitement in the history of modern fundamentalism was generated by the theology of Karl Barth, whose emphasis on biblical authority was seen by many to reflect fundamentalist concerns.

Though fundamentalists are not notably ascetic, they do observe certain taboos. Most fundamentalists do not smoke or drink alcoholic beverages and usually do not dance or attend movies and plays. At most Bible institutes and fundamentalist colleges, these practices are strictly forbidden. Worship practices may vary from denomination to denomination but are usually nonliturgical and heavily influenced by revivalism. A sermon with congregational singing and prayer are common elements of fundamentalist services.

**fundamiji** (Japanese: "dusted base"), also called *KINJI*, or *KINDAMI*, in Japanese lacquerwork, variation of the *jimaki* technique. In this kind of ground decoration, a thick layer of fine gold or silver grains is dusted onto a freshly lacquered surface and, when dry, covered with a clear lacquer. After this has dried, it is polished with powdered charcoal and given a fine finish by fingertip polishing with a mixture of linseed oil and finely powdered mudstone. When completed, the surface resembles burnished gold or silver plate.

Fine, round grains of gold or silver (*maruko*) are usually used for *fundamiji*. *Maruko* can be produced by lightly grinding gold or silver flakes between two filelike steel surfaces. A sieve is used to separate the fine grains from the coarse. During the Heian period (794–1185), uneven grains of gold produced by fil-

Four-case *inrō* with a mountain torrent design done in gold *fundamiji* on a black lacquer base, signed Tōyō, 19th century, Edo period; in the Victoria and Albert Museum, London

ing solid gold were used; this technique was called *ikakeji*.

**Fundi (Italy):** see Fondi.

**Fundy, Bay of,** inlet of the Atlantic Ocean between the Canadian provinces of New Brunswick (north and west) and Nova Scotia (south and east). It extends 94 miles (151 km) inland, is 32 miles (52 km) wide at its entrance, and is noted for its fast-running tides, which may produce rises as great as 70 feet (21 m), the highest in the world. Aside from the spectacular rock formations and forests of its shorelines and the fine agricultural lands created by dikes from its on-land marshes, the bay has come into prominence as a major potential source of hydroelectricity, but one that continues to present great engineering difficulties and other problems of feasibility.

The bay covers some 3,600 square miles (9,300 square km). Its shores are indented by numerous coves and several large deepwater harbours, the main ones at Saint John and St. Andrews in New Brunswick and Digby and Hantsport in Nova Scotia, all harbour towns that burgeoned during the great lumbering, shipping, and shipbuilding activity of the 19th and early 20th centuries. In 1948 an 80-square-mile section of shore and stream-riven hills in New Brunswick was set aside as Fundy National Park.

Steep bedrock cliffs up to 200 feet (60 m) high bound the bay and channel its waters

until they separate into two narrow niches, Chignecto Bay on the north and Minas Basin on the south. In these, the tide range is magnified by the narrowness and shape of the bay, a rise of 46 feet (14 m) being common in Chignecto Bay and 53 feet (16 m) in Minas Basin. When the tide runs out, the channels become veins of red mud, reflecting the erosion of the outcrops of red sandstone and shale along the coast. The rising tide produces a "reversing falls" at the mouth of the Saint John River, and the tidal surge up the Petitcodiac River toward Moncton has a bore, or tidal wave, that is 3 to 6 feet (1 to 2 m) high at its crest, with the tide rising a phenomenal 8 to 11 feet (2.5 to 3.5 m) per hour.

Passamaquoddy Bay, astride the Maine–New Brunswick border, over several decades has been the focus of investigations into the feasibility of harnessing its hydroelectric potential through damming or some other means. This bay's tidal flow is immense—some 70,000,000,000 cubic feet (2,000,000,000 cubic m) entering and leaving on the twice-daily turn of the tide. The tidal-power possibilities of Passamaquoddy, whose tides average an 18-foot rise, were first studied in the 1920s and have been the subject of occasional investigations ever since, but the continuing engineering difficulties and the immense costs involved, along with environmental concerns, have so far impeded any development.

**Fundy National Park,** national park in New Brunswick, Canada, on the Atlantic coast overlooking the Bay of Fundy, noted for its unusually high and fast-running tides. The park was established in 1948 and includes 8 miles (13 km) of the rugged coast, covers 80 square miles (206 square km), and reaches an elevation of 1,200 feet (365 m). The tides there run as high as 70 feet (21 m), higher than any other known place on Earth.

**Funen,** Danish FYN, second largest island (area 1,152 square miles [2,984 square km]) of Denmark. It lies between southern Jutland and Sjælland (Zealand) and is bounded by the Little Belt (strait) to the west and the Great Belt to the east, making up most of Funen *amtskommune* (county commune). The fertile clay loams of the rolling morainic landscape ("the Garden of Denmark") support agriculture (grains and sugar beets), garden-

ing, dairy farming, and cattle breeding. Stone Age burial chambers remain on the island, as well as numerous Viking relics, including the famous Ladby-skibet (12 miles [19 km] east of Odense), the burial ship of a Viking chieftain (c. 950), and a "ship monument" (grave enclosed by standing stones in the form of a ship) west of Odense. Always a stronghold of the Danish aristocracy, Funen is rich in old castles and manor houses. Two of the finest are Egeskov (1554) and Brahetrolleborg (1568; incorporating parts of a monastery founded in 1172), both in the south. The island's chief ports are the manufacturing city of Odense, Assens, Svendborg, Nyborg, Kerteminde, Middelfart, and Fåborg. Pop. (2000 est.) 439,608.

**Funes,** city, Navarra *provincia* and *comunidad autónoma* ("autonomous community"), northern Spain. It lies along the Arga River. Funes is a centre for sugar-beet cultivation, and there are gypsum quarries in the vicinity.

At the beginning of the 12th century, Funes and the neighbouring town of Viguera were granted a charter that included regulations governing relations between the Christian and Jewish communities; rules of evidence in litigation between Christians and Jews were established; ordeal by battle was forbidden and a high blood price was fixed for the murder of a Jew. Jewish landowners were required to pay tithes to the church, but in 1171 King Sancho VI freed the Jews from payment of all dues in return for an undertaking to maintain the citadel. The Jewish community had its own executive official. A list of fines levied against persons who broke the regulations survives from the 13th century, but little is known of the Jewish community of Funes after that time. Pop. (1996 est.) 2,112.

**Fung DYNASTY** (Nilotic Sudan): see Funj dynasty.

**Fung Yu-lan,** Fung also spelled FENG, Pinyin FENG YOU-LAN (b. Dec. 4, 1895, Honan, China—d. Nov. 26, 1990, Peking), outstanding Chinese philosopher of the 20th century.

Fung was educated at Peking (A.B., 1918) and Columbia (Ph.D., 1923) universities and in 1928 became professor of philosophy at Tsinghua University in Peking. His two-volume *History of Chinese Philosophy* (1934; rev. ed., 1952–53), which utilized Western historical methods, established his reputation and remains the standard general history of Chinese philosophy.

In 1939 Fung set forth his own philosophical system in *Hsin li-hsüeh* ("New Rational Philosophy"), in which he converted certain 12th-century Neo-Confucian assertions about the world into formal logical concepts. These he dealt with in a systematic manner that was new to Chinese philosophy, which traditionally had largely used assertion and metaphor. In 1950, soon after the communist triumph in China, Fung repudiated his own philosophy as idealistic, abstract, and devoid of historical and practical character, but from 1957 to 1963 he was severely attacked by Marxist-Leninist critics for continuing to advocate an idealistic philosophy. He nevertheless remained in China for the rest of his career.

**Fungi imperfecti** (fungus form-class): see Deuteromycetes.

**fungicide,** also called ANTIMYCOTIC, any toxic substance used to kill or inhibit the growth of fungi that either cause economic damage to crop or ornamental plants or endanger the health of domestic animals or humans. Most fungicides are applied as sprays or dusts. Seed fungicides are applied as a protective covering before germination. Systemic fungicides, or chemotherapeutants, are applied to plants, where they become distributed throughout the

The Bay of Fundy

tissue and act to eradicate existing disease or to protect against possible disease.

Bordeaux mixture, a liquid composed of hydrated lime, copper sulfate, and water, was one of the earliest fungicides. Bordeaux mixture and Burgundy mixture, a similar composition, are still widely used to treat orchard trees. Copper compounds and sulfur have been used on plants separately and as combinations. Synthetic organic compounds are now more commonly used because they give protection and control over many types of fungi and are specialized in application.

Cadmium chloride and cadmium succinate are used to control turfgrass diseases. Mercury(II) chloride, or corrosive sublimate, is used as a dip to treat bulbs and tubers. Other substances occasionally used to kill fungi include chloropicrin, methyl bromide, and formaldehyde. Many antifungal substances occur naturally in plant tissues. Creosote, obtained from wood tar or coal tar, is used to prevent dry rot in wood.

**fungus**, plural FUNGI, any of about 50,000 species of organisms of the kingdom Fungi, or Mycota, including yeasts, rusts, smuts, molds, mushrooms, and mildews—that lack chlorophyll and the organized plant structures of stems, roots, and leaves.

A brief treatment of fungi follows. For full treatment, see MACROPAEDIA: Fungi.

The study of fungi (Latin: "mushrooms") is called mycology (from the Greek *mykes*, "mushrooms") because mushrooms are the most conspicuous members of Fungi. Fungi contribute to the disintegration of organic matter that results in the release of carbon, oxygen, nitrogen, and phosphorus from dead plants and animals into the soil or the atmosphere. Fungi also form symbiotic and parasitic relationships with living organisms. Fifty thousand species of fungi have been described, but it has been estimated that the total number may be as high as 100,000–250,000. They can be found in the water, soil, air, plants, and animals of all regions of the world having sufficient moisture to enable them to grow. Essential to many household and industrial processes, fungi are also used in the production of enzymes, organic acids, vitamins, and antibiotics. Penicillin, a green mold whose abilities to inhibit the growth of bacteria were first discovered by Alexander Fleming in 1928, is just one of many fungi with beneficial effects on the human environment. Fungi also can destroy crops, cause such diseases as athlete's foot and ringworm, and ruin clothing and food with mildew and rot. In suitable environments, fungi can live for hundreds of years, and specimens of one genus, *Armillaria* (*q.v.*), are among the oldest and largest of living organisms.

The thallus, or body, of a typical fungus consists of a mycelium, which is a mass of branched, tubular filaments called hyphae (singular: hypha) through which cytoplasm flows. The cell walls of the hyphae are structurally complex and vary in different fungal groups. Most contain either cellulose or a tough carbohydrate substance (chitosan, chitin, or both) similar to cellulose. The cell walls serve a regulatory function in the interchange of materials between the hyphae and their external environment. The mycelium generally reproduces by forming spores, either directly or in special fruiting bodies that are generally the visible part of the fungus.

The simplest method of asexual reproduction is a fragmentation of the thallus, either by breaking off a portion of the network of hyphae or by single-cell fission that occurs in some yeasts. Another method common in yeasts is budding, a process by which the nucleus of the parent cell divides and one of the

daughter nuclei migrates into a bud on the surface of the cell and the other remains in the parent cell.

The majority of fungi reproduce asexually by the formation of bodies called mitospores either directly on the hyphae or on special sporiferous (spore-producing) hyphae, which may be grouped into intricate structures called fruiting bodies. More primitive fungi produce spores endogenously in sporangia, which are saclike fruiting bodies whose entire cytoplasmic content divides into spores. These can be either naked and flagellating (zoospores) or walled and nonmotile (aplanospores). Zoospores swim through moisture in aquatic or terrestrial environments, eventually losing their flagella and forming walls, inside which each zoospore germinates and grows into a system of hyphae.

Spores can also be produced sexually. The type of sporophore that is produced is characteristic of the group to which a fungus belongs. Even when both mitospores (spores formed by asexual means) and meiospores (spores formed by sexual means) are produced by the same fungus as it changes from an asexual to a sexual reproductive phase, they are very different in form and can be easily distinguished.

The distribution of fungi is related to the availability of food and to moisture and temperature. The soil provides an ideal habitat for a large number of species. Most aquatic fungi prefer clean, cool waters. The optimum growth temperature is usually between 68° and 86° F (20° and 30° C).

Since fungi possess no chlorophyll, they are unable to photosynthesize and must obtain their carbohydrates by secreting enzymes into the surface on which they are growing. The enzymes digest the food, which is then absorbed directly through the hyphal walls. Saprophytic fungi live off dead organisms and are partly responsible for the decomposition of organic matter. Parasitic fungi invade living organisms to obtain their food, often causing disease and death. Plants are the most common hosts, but humans and lower animals also serve as hosts. Symbiotic relationships include those between fungi and algae (lichen), plants (mycorrhizae), and certain insects.

Fungi were formerly classified in the plant kingdom and are still considered plants in some classification systems. The chitin in their structures and their ability to obtain food from an outside source, however, have caused many taxonomists to propose that they be classified in a separate kingdom, Fungi.

**fungus bug** (insect): see flat bug.

**fungus gnat**, also called MUSHROOM FLY, any member of the insect families Mycetophilidae and Sciaridae (order Diptera), small mosquito-like flies with maggots (larvae) that feed on fungi. In Sciaridae, the dark-winged fungus gnat family, the eyes of the adults almost touch

Fungus gnat (*Platylura pectoralis*)

William E. Ferguson

and the wings are usually dusky. The creamy-white or gray larvae of the genus *Sciara* may travel in armies, migrating in snakelike lines

1 cm (0.4 inch) deep in search of food or when ready to enter a resting stage (pupa). Some species of *Sciara* and some mycetophilids attack mushroom beds, sometimes completely destroying them; *S. tritici* damages the roots of wheat.

The family Mycetophilidae contains a few injurious species. The wingless adult female *Pnyxia scabiei* bores into potato tubers and causes scabs. *Platylura* larvae are predatory, feeding on small insects and worms that are killed by oxalic acid secreted on the loose, slimy webs that the larvae secrete. Larvae of several species are luminous: *Arachnocampa luminosa* lights caves in New Zealand. It spins webs with hanging sticky strands to catch flying insects for food.

**fungus weevil**, any of the approximately 2,400 species of the beetle family Anthribidae (order Coleoptera) usually found on dead twigs or fungi. These insects are between 0.5

Coffee bean weevil (*Araecerus fasciculatus*) emerging from a hole in a dried coffee bean

Walter Dawn

and 50 mm (0.02 and 2 inches) long, and the head is prolonged to form a short beak called a snout.

Some species have antennae that may be longer than the body; others have short antennae. Fungus weevils occur mainly in the tropics. The coffee bean weevil (*Araecerus fasciculatus*) is an important pest.

**Funj** DYNASTY, also spelled FUNG, line of kings that ruled in the Nilotic Sudan of Eastern Africa in the 16th–19th century. At its greatest extent, Funj authority stretched westward across the southern Gezira region into Kordofan and southward to the gold-bearing district of Fāzūghli.

The Funj capital, the city of Sennar, on the left bank of the Blue Nile above its confluence with the White Nile, was founded by 'Amārah Dunqas in 1504–05. The Funj expanded northward from this region at the same time the 'Abdallabi dynasty was extending its dominion southward from the region of Subah.

The two dynasties met and clashed near 'Arbaji (on the Blue Nile in the Gezira), and the victorious Funj ruled thereafter as high kings of the region in partnership with the 'Abdallabi sheikhs, whose authority, at the time of conflict, extended as far north as the Third Cataract of the Nile. A revolt early in the 17th century by the 'Abdallabi chief 'Adjib al-Mandjilak against the Funj sultan 'Abdlan ibn Unsa strained the Funj-'Abdallabi duumvirate until peace was restored by Sheikh Idris ibn Muhammad al-Arbab (d. 1650).

The Funj dynasty was early converted to Islam; 'Amara (d. 1533/34) had Muslims in his train, and 'Abd al-Qādir I (d. 1557/58) bore a Muslim name.

The Funj first expanded westward across the hills of Sakadi and Muya about 1554 and then across the White Nile (whose shores were dominated by the pagan Shilluk), where they

established a bridgehead at al-Ays. Bādi II Abū Daqn (reigned 1644/45–1680) continued the Funj conquest by defeating the Shilluk and by raiding and later imposing tributary status on Takali, a Muslim hill state south of Kordofan. The plains of Kordofan proper did not fall to the Funj until the reign of Bādi IV Abū Shulūkh (reigned 1724–62). Expansion eastward was barred by Ethiopia, with which the Funj waged two wars, the first in 1618–19 and the second, in which the Funj under Bādi IV were victorious, in 1744.

Despite its continuing expansion, the Funj dynasty was racked by internal conflict, marked by the frequent deposition of its kings. The development under Bādi II of a slave army, which subsequently settled around the capital, increased tensions between the Funj dynasty and its warrior aristocracy; the latter rose unsuccessfully against Bādi III in the early 18th century and successfully against his son Unsa III before 1720. During the reigns of Unsa's successor, Nul, who was connected to the Funj through his mother, and Nul's son Bādi IV, the dynasty's authority was restored for some 40 years. But Bādi IV was overthrown c. 1762 by his commander and viceroy in Kordofan, Abū Likaylik, and the Funj dynasty, though it continued nominally in power thereafter, had no real authority. In 1821 it was supplanted by the Turkish government of Egypt.

In present-day Sudan the census bureau uses the term Darfunj (Funj tribes) to describe a number of ethnically and linguistically different peoples living in the southeastern part of the country. This area had represented an ethnic-linguistic mixture when the Funj arrived, and the kingdom, by its nature, increased the mix. Among those designated as Funj tribes, the Gule claim that their chiefs are the descendants of the Funj kings.

**Funk, Isaac Kauffman** (b. Sept. 10, 1839, Clifton, Ohio, U.S.—d. April 4, 1912), American publisher who was also a Lutheran minister, religious journalist, Prohibition Party publicist, and spelling reformer.

Funk graduated from Wittenberg College, Springfield, Ohio, in 1860 and was ordained a Lutheran minister the following year. Resigning his pulpit in 1872 he traveled in Europe and the Middle East. After his return to the United States he helped edit the *Christian Radical*. Funk entered the publishing business in 1876, his first publication being an aid to ministers, the *Metropolitan Pulpit*.

In 1877, with a former classmate, Adam Willis Wagnalls, he founded I.K. Funk & Company, afterward (from 1891) Funk & Wagnalls Company, in New York City. The firm became best known for *A Standard Dictionary of the English Language* (1st ed., 1893; subsequent editions entitled *A New Standard Dictionary of the English Language*).

**Funk, Walther** (b. Aug. 18, 1890, Trakehnen, East Prussia, Ger.—d. May 31, 1960, Düsseldorf, W.Ger.), German Nazi and economist who was economics minister of the Third Reich from 1938 and president of the Reichsbank from 1939.

Funk attended universities at Berlin and Leipzig before joining the German Army at the outbreak of World War I. He was discharged in 1916 as being unfit for service. Having started in newspaper work in 1912, he became editor of the leading German financial and economic daily, the *Berliner Boerser Zeitung*, in 1922. Shortly thereafter he joined the Nazis and in 1931 was called to Hitler's personal staff as economic adviser; in this post he acted as a middleman between Hitler and the German industrialists.

Funk was appointed economics minister in 1938 but operated under the supervision of Hermann Göring, who was plenipotentiary general of the four-year plan; on Jan. 20, 1939, Funk replaced Hjalmar Schacht as pres-

ident of the Reichsbank. Funk participated in the economic planning for the attack on the Soviet Union and was active in the Nazi program of discrimination against Jews. Taken prisoner by U.S. troops in May 1945, he was indicted by the International Military Tribunal at Nürnberg, Aug. 29, 1945.

In his defense he described himself as a little man "who was frequently allowed up to the door but not in." Göring himself told the court that Funk was an "insignificant" subordinate. The court, nevertheless, found him guilty of crimes against the peace, war crimes, and crimes against humanity, and on October 1 he was sentenced to life imprisonment. He was released from prison on May 16, 1957.

**Funk & Wagnalls dictionaries**, family of English-language dictionaries noted for their emphasis on ease of use and current usage.

The first Funk & Wagnalls dictionary was *A Standard Dictionary of the English Language* (1893). It espoused four policies pertinent to its initial and future publications: the ordering of definitions according to current, rather than historical, usage; the appearance of etymologies at the end of definitions, rather than at the beginning; the use of one alphabetical list for all entries, rather than separate sections for geographical, biographical, mythological, or biblical terms; the use of lowercase initial letters for all entry titles except proper nouns.

Isaac Funk, the editor of the *Standard*, believed strongly in accurate phonetics and simplified spellings whenever possible, a policy to which Funk & Wagnalls still adheres. In addition to the present unabridged *New Standard*, the company publishes a line of several dictionaries, most of which are based on the *Standard Dictionary of the English Language* (International Edition), a new work published in 1958. These spinoffs include, among others, the *Comprehensive Standard International Dictionary*, a reprint of the *Standard* with encyclopaedic matter added; and the *Standard College Dictionary*, an abridged version of the *Standard*. The *Standard Encyclopedic Dictionary* is a reprint of the latter with the addition of encyclopaedic matter.

**funnel weaver**, also called GRASS SPIDER, any of certain members of the spider family Agelenidae (order Araneida). Agelenids are notable for their funnel-shaped webs; they are

Funnel weaver (*Agelena naevia*)  
Tom Myers

a common group with many species that are distributed worldwide. The webs are built in the grass, under boards and rocks, and among debris. *Agelena naevia*, a common North American species, varies greatly in size and colour. The body of the male may be up to 8 millimetres (about 1/3 inch) long; the female grows to about 19 millimetres (about 3/4 inch). Two wide, dark stripes often extend the length of the anterior part of the body. The body colour ranges from pale yellow to dark reddish brown. The spider lives for one year.

**funnel-web spider**, any species of spider belonging to several genera in the family Dipluridae. The most important genera are *Eva-*

*grus*, *Brachythele*, and *Microhexura* in North America; *Trechona* in South America; and the poisonous members of the *Atrax* genus in Australia. The spiders are named for their webs, which are shaped like funnels opening wide at the mouth of the tube; insect prey are caught by the spider at the funnel's mouth.

The species *Atrax robustus* and *A. formidabilis* are large, brown bulky spiders that are much feared in southern and eastern Australia because of their venomous bites. Several human deaths from the bites of these aggressive spiders have been recorded in the Sydney area since the 1920s. An antidote to the main toxin in their venom has been developed which is effective if administered to victims soon after they have been bitten.

**Fur**, people after whom the westernmost province of The Sudan, Darfur, is named. The Fur inhabit the mountainous area of Jebel Marra, the highest region of The Sudan. The languages spoken by Fur groups make up one of the six branches of the Nilo-Saharan family.

They had powerful kingdoms in the 16th century, extending to the Nile. Arab incursions forced them northward into the mountains, where they successfully developed a form of terrace farming. Cotton and tobacco are the main cash crops. Also cultivated are cereals such as wheat and corn (maize), as well as peanuts (groundnuts), beans, hibiscus, tomatoes, potatoes, onions, garlic, and pumpkins. The temperate climate of the mountains permits the growing of apples and strawberries.

At the end of the 16th century an Islamic sultanate was founded by Suliman Solong, and Arab dress and names have characterized the Fur since. Today they are entirely Muslim. Fur society is divided between wealthy landowners and serfs. Smiths, tanners, and other artisans constitute lower castes. Bridewealth is paid to the daughters' parents in cattle and cloth. Polygyny is practiced by the wealthy few, and divorce is very common.

**fur**, fine, soft, hairy covering or coat of mammals that has been important to mankind throughout history, chiefly for warmth but also for decorative and other purposes.

The pelts of fur-bearing animals are called true furs when they consist of two elements: a dense undercoat called ground hair, and longer hairs, extending beyond that layer, called guard hair. The principal function of ground hair is to maintain the animal's body temperature; that of guard hair is to protect the underlying fur and skin and to shed rain or snow. Pelts that lack either element are not true furs, although they are still used commercially as furs. Persian lamb, for example, has no guard hair, while kid and pony possess no ground hair.

Furs have been used principally to fashion outer garments; this is also true for the modern fur industry. A variety of animals are bred or trapped for their pelts, including those that bear the luxury furs (sable, chinchilla, ermine, and mink) and others whose fur is of lesser value (such as rabbit and squirrel). Other commercially important furs include the various species of fox and lamb; beaver, marten, raccoon, skunk, otter, and seal; as well as leopard, lynx, ocelot, and wolf.

Animals were originally hunted or trapped for food, and their pelts were rendered to provide protective clothing. As civilization developed, furs became less a necessity and more a luxury. The finer and more exotic furs were a symbol of affluence and status in the ancient societies of China, Greece, and Rome. Over the centuries furs remained a prized and commercially important commodity. The trapping and trading of furs became a major business enterprise among early North Amer-

ican settlers, and those who pursued it were responsible for much of the exploration of the northern United States and Canada.

A large and profitable international market for furs has developed; among the major producers are the United States, Canada, and the Scandinavian countries. Fur-bearing animals that are bred and raised on fur farms (or ranches) include mink, fox, marten, and chinchilla. Mink pelts constitute the majority of pelts produced annually, with most coming from mink ranches. Using scientific methods of breeding, planned diets, and other specialized procedures, farm operators have produced furs of the highest quality. Controlled breeding has also resulted in desirable mutations.

Animals commonly trapped for their furs include raccoon, beaver, skunk, and muskrat. The chief trapping method uses baited and concealed traps that are usually placed during the season that the coat of the particular animal is at its fullest—for most animals, at the beginning of winter. Trapping methods are regulated and catch quotas are set by the governments of many countries. Some aquatic mammals, such as fur and harp seals, are also hunted for their furs.

Most pelts are sold at auctions to merchants, manufacturers, and their brokers. Major auction centres are New York City, Montreal, and St. Petersburg.

The first step in processing raw pelts is dressing. The dressing of furs involves several steps, the exact number of which is determined by the particular fur being dressed. Generally speaking, a fur is cleaned, softened, fleshed (extraneous flesh is removed), and stretched. The skin is tanned by a process called leathering. Many furs are then dyed, bleached, or tipped (dyeing the guard hair only) using various synthetic compounds called fur bases.

The making of dressed furs into such garments as coats, stoles, wraps, and hats is called furriery. Much of the process is done by hand. The cutter matches pelts according to colour and texture and cuts the skins to conform to the designer's pattern. The skins are then made into sections that are dampened and stretched and nailed to fit a pattern on a wooden nailing board. After drying on the board, they are sewn together. Sewing, performed on power-driven machines, requires great skill.

Fur coats are made by one of two processes: the letting-out technique or the skin-on-skin method. The letting-out process involves slicing a skin into narrow diagonal strips and then sewing them together to form a longer and narrower strip that will run the full length of the coat. The skin-on-skin process is much simpler and consists of sewing one full skin to another. After sewing the fur is glazed, which is accomplished by dampening the fur, arranging the hair in the desired direction, and then slowly drying it to keep the hairs aligned.

Since the late 20th century, numerous animal-rights groups, particularly People for the Ethical Treatment of Animals, have mounted a high-profile anti-fur campaign. Controversy has surrounded some of the activists' tactics, especially the throwing of paint at fur coats and the disruption of fashion shows.

**fur seal**, any of several eared seals of the family Otariidae valued for the quality of their fur. The northern fur seal (*Callorhinus ursinus*) is a migratory inhabitant of northern seas, breeding in summer on the Pribilof, Komandor (Commander), and other islands. Prized for its chestnut-coloured underfur, it is a gregarious, vocal animal that feeds on fish and other marine animals. The adult male is deep brown in colour with a grayish mane and grows to about 3.1 m (10 feet) in length and 300 kg (660 pounds) in weight; the female is dark gray and

Australian fur seal (*Arctocephalus pusillus doriferus*)  
Tierbilder Okapia—Frankfurt am Main

grows to about 1.5 m (5 feet) and 60 kg (132 pounds). In 1911, after more than a century of extensive slaughter, the northern fur seal was placed under protection. By the late 20th century there were thought to be some one million northern fur seals, but this number was declining. The overfishing of its prey and environmental fluctuations were believed to be partly responsible.

The eight species of southern fur seals (*Arctocephalus*) are distributed in the Southern Hemisphere, except for a herd of Guadalupe fur seals (*A. townsendi*) on Guadalupe Island off the northwest coast of Baja California. Southern fur seals are gray to brown or black in colour with chestnut-coloured underfur. Length averages about 1.2–1.8 m (4–6 feet), but the South African, or Cape, fur seal (*A. pusillus*) and the Australian fur seal (*A. pusillus doriferus*) grow to lengths and weights of about 2.5 m (8 feet) and 300 kg in the male, 1.8 m and 120 kg (265 pounds) in the female. Like the northern form, southern fur seals are gregarious and carnivorous. Some species, including the once-numerous New Zealand fur seal (*A. forsteri*), the Galápagos fur seal (*A. galapagoensis*), and the Juan Fernandez fur seal (*A. philippii*), all of which were hunted nearly to the point of extinction, have been protected by law. The harp seal (*q.v.*) is a fur-bearing northern seal of a different family (Phocidae).

**Fur Seal Islands** (Alaska, U.S.): see Pribilof Islands.

**furan**, any of a class of organic compounds of the heterocyclic aromatic series characterized by a ring structure composed of one oxygen atom and four carbon atoms. The simplest member of the furan family is furan itself, a colourless, volatile, and somewhat toxic liquid that boils at 31.36° C (88.45° F). It is usually converted by hydrogenation to tetrahydrofuran, which is used as a solvent and for production of adipic acid and hexamethylenediamine, the raw materials for nylon-6,6. Several other members of the furan family are produced on a large scale for use as solvents and chemical raw materials. The first furan compound discovered was pyromucic acid (2-furoic acid), prepared in 1780. The aldehyde furfural, used as a solvent in petroleum refining, is manufactured from corn cobs and oat hulls by treatment with acid.

Many sugars exist in molecular forms called furanoses, possessing the tetrahydrofuran ring system. Important examples are provided by ribose and deoxyribose—which are present in the furanose form in nucleic acids, the heredity-controlling components of all living cells—and fructose.

**Furchgott, Robert F(rancis)** (b. June 4, 1916, Charleston, S.C., U.S.), American pharmacologist who, along with Louis J. Ignarro and Ferid Murad, was awarded the 1998 Nobel Prize in Physiology or Medicine for the discovery that nitric oxide (NO) acts as a sig-

naling molecule in the cardiovascular system. Their combined work uncovered an entirely new mechanism by which blood vessels in the body relax and widen.

After attending the University of North Carolina (B.S., 1937) and Northwestern University (Ph.D., 1940), Furchgott in 1956 joined the faculty at SUNY-Brooklyn, where he stayed until 1988, when he became an adjunct professor at the University of Miami School of Medicine in Florida. In the work for which he shared the Nobel Prize, Furchgott demonstrated that cells in the endothelium, or inner lining, of blood vessels produce an unknown signaling molecule. The molecule, which he named endothelium-derived relaxing factor (EDRF), signals smooth muscle cells in blood vessel walls to relax, dilating the vessels. Furchgott's work eventually was linked with that done by Murad, who showed that nitroglycerin and several related heart drugs induce the formation of nitric oxide, a gas that acts to increase the diameter of blood vessels; Ignarro later demonstrated that EDRF was nitric oxide. Researchers suggested that the gas could be a key to improved treatments for heart disease, shock, and cancer.

**Furetière, Antoine** (b. Dec. 28, 1619, Paris—d. March 14, 1688, Paris), French novelist, satirist, and lexicographer, remarkable for the variety of his writing.

Furetière entered the legal profession but soon resigned his office and took Holy Orders to qualify himself for benefices, which provided an income that enabled him to pursue his literary vocation. After publishing three books of comic and satirical verse, he wrote *Nouvelle Allégorique ou Histoire des derniers troubles arrivés au royaume d'Eloquence* (1658), a facetious survey of the contemporary Parisian world of letters, in which he wrote so favourably of the members of the Académie Française that he was, in 1662, himself elected.

He soon forfeited the goodwill of his colleagues, however. His *Le Roman bourgeois* (1666) was a pioneer work in the history of the French novel because it dealt realistically with the Parisian middle classes instead of "heroic" personages or picaresque vagrants. But it gave offense to the academy, not so much by the formlessness of its construction as by its fidelity to a subject matter deemed unworthy of an academician. Furetière incurred worse displeasure when, late in 1684, he revealed his intention of publishing his own universal dictionary of the French language, on which he had been working for some 40 years. This enterprise infuriated some of his fellow academicians, whose own long-projected dictionary was still incomplete. They expelled him from the academy, and, though King Louis XIV tried to protect him, the rest of Furetière's life was spent in controversy with his former colleagues. His great *Dictionnaire*, recognized as more comprehensive and much more useful than the academy's, was first printed in Holland in three volumes in 1690.

**Furies** (Greco-Roman goddesses): see Fury.

**furlong**, old English unit of length, based on the length of an average plowed furrow (hence "furrow-long," or furlong) in the English open- or common-field system. Each furrow ran the length of the 40 × 4-rod acre, or 660 modern feet. The standardization of such linear units as the yard, foot, and inch—begun in Edward I's statute of 1305—recognized the traditional sizes of rods, furlongs, and acres as fixed and therefore simply redefined them in terms of the newly standardized units. Thus, the furlong, often measured as 625 northern (German) feet, became 660 standard English feet, and the mile, always 8 furlongs, became 5,280 feet. Today, the furlong is used almost exclusively in horse racing.

**furnace**, structure in which useful heat is produced by combustion or other means. Historically, the furnace grew out of the fireplace and stove, following the availability of coal for heating. A coal furnace is made up of sev-

Forced warm-air furnace

eral elements: a chamber containing a grate on which combustion takes place and through which ashes drop for disposal; a chimney to carry away smoke and provide a draft of air; another source of air supply to help burn volatile gases and hydrocarbons; and a metal surface over which the hot gases pass and which transfers heat to circulating water or air. Coal furnaces are still widely used in industry, where they are usually equipped with mechanical stokers.

Chemical energy is transformed into heat by burning fuels such as coal, wood, oil, and hydrocarbon gases. Electrical energy is transformed into heat in an electric furnace or an electric burner (see electric furnace). Solar radiation energy is used in the solar furnace, a device for concentrating large amounts of solar energy into a small area. Nuclear energy is transformed into heat energy in atomic reactors, so that these function as furnaces in nuclear power stations. Furnaces may apply their heat to other devices, as boilers, ovens, and kilns, or they may apply it directly to material in the course of being processed, as in steel production.

**furnace oil**: see fuel oil.

**Furnariidae**, bird family, order Passeriformes, containing about 220 species in nearly 60 genera, limited in distribution to Central and South America. This is one of the most diverse bird groups, with many body plans and popular names. Because of the nesting habits of several well-known species, the name ovenbird is often applied to the family generally, but many are called castle-builders, firewood gatherers, earth creepers, foliage gleaners, miners, spine tails, and reed haunters. In appearance, habitat, and food habits, furnariids variously resemble larks, wrens, creepers, nuthatches, titmice, thrushes, and warblers, but the family is united by common features of the skeleton and muscles. Most are brown to rufous and have rufous stripes on the underwing.

**Furneaux, Tobias** (b. Aug. 21, 1735, Swilly, near Portsmouth, Hampshire, Eng.—d. Sept. 19, 1781, Swilly), British naval officer and explorer who was first to circumnavigate the globe in both directions.

On Capt. Samuel Wallis' westerly-directed circumnavigation in the Royal Navy ship "Dolphin" (1766–68), Furneaux was among the first Europeans to reach Tahiti. As commander of the "Adventure," he took part in Capt. James Cook's second voyage to the Pacific (1771–75). Sailing eastward from the Cape of Good Hope, the "Adventure" became separated from Cook's vessel, the "Resolution," on Feb. 8, 1773. Furneaux then continued into Australian waters and explored and charted the east and south coasts of Tasmania. The ships were reunited at Queen Charlotte Sound, New Zealand, and went on to Tahiti and the Friendly, now Tonga, Islands. On their way back to Queen Charlotte Sound, the vessels again became separated (Oct. 29/30, 1773). In New Zealand 10 of Furneaux's crew were captured, killed, and eaten by Maoris.

When the "Adventure" reached England in July 1774, before the arrival of Cook, it had aboard the first South Sea islander to visit the British Isles. Furneaux commanded the "Syrén" in the British attack on Charleston, S.C. (June 28, 1776).

**Furneaux Group**, cluster of islands and rocks in Bass Strait off northeastern Tasmania, Australia. The largest are Flinders (about 800 sq mi [2,080 sq km]), Cape Barren, Clarke, and Chappell. The islands are generally mountainous with rugged coastlines. Major occupations are sheep and cattle breeding and the processing and exporting of muttonbird oil and carcasses. Whitemark, on Flinders Island, is the largest town. The islands were sighted by Tobias Furneaux of HMS "Adventure" in 1773 and were surveyed in 1798 by Matthew Flinders. Pop. (1996) 924.

**Furnes (Belgium)**: see Veurne.

**Furness**, region, county of Cumbria, England. Except for a narrow coastal plain, the area is predominantly upland, with such eminences as the Old Man of Coniston and Wetherlam. Principal rivers are the Duddon, Leven (draining Windermere), and the Crake (draining Coniston Water), flowing south into Morecambe Bay on the Irish Sea coast. Between the Duddon Estuary and Morecambe Bay is the Isle of Walney, 8 mi (13 km) long and 1 mi wide. Most of Furness is in the Lake District, and Roudsea Wood is a nature reserve.

Furness became important in the Middle Ages because of its abbey, the ruins of which are situated north of Barrow-in-Furness. It was founded in 1127 by Benedictine monks from Savigny in France who later joined the Cistercian order. They were granted the lordship of Furness by Stephen (ruled 1135–54), and the abbey became one of the richest in England. At Conishead was an Augustinian foundation, and at Cartmel is the fine parish church of a former abbey (1188). Ulverston became a market town for the region.

Industry in the area was based on the iron ore of the limestones in the southwest, worked from early times and exploited by the monks of Furness. Production reached a peak in the 1880s and has since declined. Opening of the Furness Railway (1846) initiated industrial development, and Barrow grew as an ore-exporting port and a shipbuilding and iron and steel centre. Decline of these industries in the 20th century resulted in heavy unemployment, and attempts to attract new manufacturing have been handicapped by the region's inaccessibility. Farming remains an important activity, with emphasis on fat lambs and store cattle, while tourism has become increasingly significant. A coastal railway connects Barrow and the region with Carlisle and Lancashire.

**Furness, Frank Heyling** (b. 1839, Philadelphia—d. June 27, 1912, Media, Pa., U.S.), U.S. architect, significant for the forceful originality of his buildings and for his influence on Louis H. Sullivan, who was a draftsman in 1873 for the Philadelphia firm of Furness and Hewitt (later Furness, Evans, & Company).

The work of Furness, who was familiar with the architectural ideas of Ruskin and Viollet-le-Duc, is largely in the Romantic Revival tradition of the Neo-Gothic. His highly personal style is expressed in his polychromatic decoration and his massive geometric ornamentation, the shapes of which were frequently abstractions of forms found in nature. They contributed much to the development of Sullivan's theories of organic architecture and ornamentation. Furness' major works include the Pennsylvania Academy of the Fine Arts (1872–76), the Provident Life and Trust Company Bank (1878–79; demolished), and an addition (1892–94) to the Broad Street Station of the Pennsylvania Railroad. Besides his

Provident Life and Trust Company Bank, Philadelphia, by Frank Furness, 1879

J.L. Dillon & Co. Inc

Philadelphia works, Furness designed buildings throughout Pennsylvania and also in Delaware and Maryland.

**Furness, Horace Howard** (b. Nov. 2, 1833, Philadelphia—d. Aug. 13, 1912, Wallingford, Pa., U.S.), U.S. compiler, with his son and others, of various editions of 20 of Shakespeare's plays.

Graduated from Harvard in 1854, Furness was admitted to the bar in 1859 but soon devoted himself to the study of Shakespeare. He accumulated a collection of illustrative material of great richness and extent and brought out in 1871 the first volume (*Romeo and Juliet*) of the variorum edition, designed to represent and summarize the textual, critical, and annotative conclusions of the best authorities. Succeeding volumes appeared at regular intervals until the posthumous *Cymbeline* in 1913. Furness was conservative in his methods but sound in his judgments, and he combined erudition with sanity and humour. His wife, Helen Kate Furness (1837–83), compiled *A Concordance to Shakespeare's Poems* (1874); and his son and namesake (1865–1930) was a partner in and successor to his father's work and edited his *Letters* (1922).

**Furniss, Harry** (b. March 26, 1854, Wexford, County Wexford, Ire.—d. Jan. 14, 1925, Hastings, East Sussex, Eng.), British caricaturist and illustrator, best known for his political and social lampoons.

Mainly self-taught, he settled in London in 1873 and, before turning wholly to free-lance work in 1894, became very popular as a staff artist for *The Illustrated London News* (1876–84) and *Punch*. In his parliamentary cartoons he emphasized idiosyncrasies of face and dress: an amusing example is the strip cartoon "Getting Gladstone's Collar Up." He also designed a famous commercial "tramp" poster for a brand of soap ("I used your soap two years ago and have not used any other since"). Strongly critical of the Royal Academy, he held in 1887 an exhibition of parodies of the work of leading Burlington House exhibitors,

and in 1890 published *Royal Academy Antics*. He illustrated many books, including Lewis Carroll's *Sylvie and Bruno* (1889) and complete editions of Dickens (1910) and Thackeray (1911). In 1912–13 he worked as a film

"Getting Gladstone's Collar Up," cartoon by Harry Furniss, c. 1876–84

By courtesy of the trustees of the British Museum, photograph, J.R. Freeman & Co. Ltd

writer, actor, and producer for Thomas Edison in New York City and London; *Our Lady Cinema* (1914) outlined his hopes for that art. He was also a novelist, essayist, and writer of art instructional manuals.

**furniture**, household equipment, usually made of wood, metal, plastics, marble, glass, fabrics, and related materials and having a variety of different purposes. Furniture ranges widely from the simple pine chest or stickback country chair to the most elaborate marquetry work cabinet or gilded console table. The functional and decorative aspects of furniture have been emphasized more or less throughout history according to economics and fashion. Chairs are always for sitting in, but some are more comfortable or more beautiful than others. The ideal of furniture design is to integrate utility, craftsmanship, and beauty into a harmonious whole. Accessory furnishings are smaller subsidiary items such as clocks, mirrors, tapestries, fireplaces, panelling, and other items complementary to an interior scheme.

A brief treatment of furniture follows. For full treatment, see *MACROPAEDIA: Decorative Arts and Furnishings; Industries, Manufacturing.*

Furniture is usually movable, though it can be built-in, as is common in kitchens and bathrooms. It need not be domestic—there is office furniture, hospital furniture, and church furniture. Sometimes lampposts, benches, and fountains are called "street furniture." Curtains, hangings, cushions, and other fabric items are known as soft furnishings. Furniture implies a degree of permanence; however, there is travelling furniture—the military chests of 19th-century England are one example of furniture designed almost as luggage.

Stylistically furniture is closely allied to architecture and to interior design. It has usually followed the architectural fashions of its day—not surprisingly, since furniture was designed, often by architects, to enhance and harmonize with interiors. One of the foremost architects who became celebrated as an interior designer and furniture designer was the Scottish architect Robert Adam of the 18th century. It is a curious feature of 20th-century architecture, particularly that of the modern movement of the 1920s and '30s, that architects turned their attention in particular to the design of chairs, often using "modern" materials such as tubular steel and, later, plastic. Charles Renzie Mackintosh, Le Corbusier, Marcel Breuer, Ludwig Mies van der Rohe, Charles Eames, and Alvar Aalto are among those modern European architects whose chair designs became classics.

Furniture ornamentation usually follows that of architecture, so that in the Middle Ages pointed arches and linenfold panelling were prevalent decorative modes. Later such mo-

tifs as columns, arches, friezes, mouldings, and pediments appeared. Twentieth century furniture, like its architectural counterpart, eschewed ornament and instead emphasized utility, line, and materials.

Many crafts may be employed to ornament furniture. These include the making of types of metal hardware, such as drawer and door han-

dles or keyhole surrounds; marquetry, using different coloured woods to create a decorative design; carving; gilding; painting; turning; lacquerwork; and inlays of ivory, tortoiseshell, or porcelain. Clear or mirrored glass may also enhance a piece of furniture.

After a period of relative dormancy in the early Middle Ages, the craft of making furniture was revived in the 14th and 15th centuries with an increase in affluence. About this time many innovative types of cupboards, boxes with compartments, and various sorts of desks began to appear. With the rise of veneering and the growing sophistication of carpentry techniques, the profession of cabinetmaking was born, followed by that of chairmaker, which has remained a separate branch of furniture making ever since.

Continued affluence of the 17th and 18th centuries gave the furniture trade another boost. The importance of cabinetmaking, coupled with increased demands for furniture, led in turn to specialization and division of labour. Now instead of one man making an entire cabinet, there were turners, veneer makers, carvers, upholsterers, and finishers—all performing separate operations in sequence. In the 19th century another important division occurred between those who made the furniture and those who sold it.

The modern furniture industry bears a close resemblance to numerous other industries in which mechanization and mass production are central to the manufacturing process. Timber is cut to usable sizes in a main conversion shop and brought to the required moisture content in a kilning section. After drying, the wood proceeds to the planing and jointing shops, where it is reduced to the required sections and any tenoning, dowelling, or dovetailing is performed. It is then veneered and passed to the assembly shop. Furniture assembly lines usually do not move continuously; rather the work is normally pushed by hand over a series of rollers as each stage is finished. Next in sequence are the sanding, finishing, fitting, and finally inspection and shipping.

With the modernization of the furniture-making process, the use of natural wood has declined sharply over the years. Natural wood tends to swell and shrink with changes in atmospheric pressure and humidity. It has also become very expensive because of reduced timber supplies and the high percentage of waste involved during the various cutting operations. As a result, furniture has increasingly been made from plywood, chipboard, plastic and metal, with natural wood going into veneers.

**Furnivall, Frederick James** (b. Feb. 4, 1825, Egham, Surrey, Eng.—d. July 2, 1910, London), English literary scholar who, partly

by his own efforts in textual criticism and partly by founding learned societies, especially the Early English Text Society, was instrumental in initiating a major revival in the study of medieval English literature. Though he first studied law and was called to the bar in 1849, he came to divide his energies between scholarship and social activism, primarily in Christian Socialism and the founding of the Working Men's College, London (1854).

His interest in medieval English works was chiefly literary, but he also valued them for their illumination of social history and considered it a duty to his countrymen to make them available in accurate editions. Of the many editions that he himself prepared, including other of Chaucer's works, the most important was the "Six-Text" edition (1866–82) of the *Canterbury Tales*. He did much to foster the

Furnivall, pencil sketch by Charles Haslewood Shannon, c. 1911; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

study of Shakespeare, of John Wycliffe, and of the ballad; he also originated the concept and assisted in the preparation of *A New English Dictionary on Historical Principles*, now the *Oxford English Dictionary*.

**furo**, Japanese-style bath, typically using water heated to 110° F (43.3° C) or hotter. It is claimed that, because the bather may linger in the wooden or metal tub, the *furo* may have properties for the therapeutic relaxation of tensions. To achieve cleanliness, the bather washes before entering the tub. In bathrooms in private Japanese homes and in public bathhouses, the bathing facilities are always constructed separately from the washing and toilet facilities.

The *furo* in a private home has social aspects. Members of a large family usually bathe in strict order, with the older members bathing first. Mothers bathe with children too young to be left alone. Water for the *furo* is usually heated specifically for that purpose, so all the members of a family bathe in close sequence.

The *furo* in a public bathhouse, called a *senjo*, is common throughout Japan. It has its counterparts in youth hostels, hotels, dormitories, and inns. An attendant sells tickets at the entrance. Having paid, the bather enters the public dressing room for the appropriate sex. Clothing goes into lockers or into plastic or rattan baskets that are then placed on shelves. The bather passes through another door into the shower or washroom; once cleansed, the bather enters a soaking pool in a separate, attractive room of almost any shape. The bather stands in hot water that is about chest-deep, the pool usually accommodating 10 or more persons.

The *furo*, with its separation of the washing and bathing phases, has sparked the popularity of hot-water soaking in other countries, especially of the hot tub during the late 1970s in the United States. Today several firms specialize

in the construction of wooden Japanese-style bathtubs.

**Furphy, Joseph**, pseudonym TOM COLLINS (b. Sept. 26, 1843, Yering, near Yarra Glen, Vic., Australia—d. Sept. 13, 1912, Claremont, W. Aus., Australia), Australian author whose novels combine an acute sense of local Australian life and colour with the eclectic philosophy and literary ideas of a self-taught workman.

Furphy  
By courtesy of the Australian Information Service

The son of Irish immigrants, Furphy worked as a thresher, teamster, and gold miner before settling down in 1884 at his brothers' foundry at Shepparton. There he wrote a picaresque novel, *Such Is Life* (1903), written as excerpts from the diary of Tom Collins. Furphy's other major works, *Rigby's Romance* (serialized 1905; published in book form, 1921) and *The Buln Buln and the Brolga* (published posthumously in 1948), were written from chapters cut from the original of *Such Is Life*. His *Poems* were published in 1916.

**Furrer, Jonas** (b. March 3, 1805, Winterthur, Switz.—d. July 25, 1861, Bad Ragaz), Swiss statesman, president of the Swiss Confederation four times.

A doctor of jurisprudence and lawyer of national renown, Furrer became, after 1839, leader of the Zürich liberals but only reluctantly aspired to political office. In the cantonal assembly, he rose to the vice presidency (1842) and later the presidency (1846), serving also in 1846 as president of the confederation Diet. During the Sonderbund War (1847), in which seven Catholic cantons formed a separatist confederation, he was a partisan of moderation. Following the adoption of a new federal constitution (September 1848), he was elected first president of the confederation (Bundespräsident) and was subsequently reelected three times (1852, 1855, 1858).

After the European revolutions of 1848, Furrer chose a moderate course in granting asylum to foreign revolutionaries in the face of conflicting demands of foreign powers and native radicals. Between his terms as Bundespräsident, he headed the Department of Justice, where his decisions helped define the proper spheres of federal and cantonal power.

**Fursey, SAINT**, also called FURSA, Latin FURSEUS (b. c. 567, near Lough Corrib?, Ire.—d. c. 650, Ponthieu, Fr.; feast day January 16), monk, visionary, one of the greatest early medieval Irish monastic missionaries to the Continent. His celebrated visions had considerable influence on dream literature of the later Middle Ages.

First educated under Brendan the Navigator, Fursey later became a monk at the monastery of Clonfert, in County Galway, and was ordained priest. He later founded a monastery at Rathmat (probably in modern County Clare), which became one of Ireland's major monastic centres. The extent of his apostolate is evident in places named for him in Galway, Louth, and Cork.

After 630 Fursey left Ireland with his brothers Foillan and Ultán for Britain, where they

were welcomed by the Christian king Sigeberht of East Anglia. They assisted Sigeberht and Felix in Christianizing the kingdom and in introducing monasticism. About 640 Fursey founded the monastery of Cnobresburgh, near modern Yarmouth, Norfolk, which became the centre of his ministry. He sailed to Gaul some time between 640 and 644 and established himself in Neustria (in present-day Normandy), where he was well received by Clovis II. About 644 he founded a monastery at Lagny, near Paris. On a later journey he died, and afterward his body was transferred to Péronne, where his shrine became a great pilgrimage site; the monastery there remained an Irish centre through the 8th century.

Fursey's visions, which he was said to have experienced throughout his life, became widely known through accounts by the Venerable Bede in his *Ecclesiastical History of the English People* (8th century), which also contains the earliest life of Fursey, written by an anonymous contemporary monk; and by Aelfric Grammaticus (10th century). The visions included demoniac assaults, conversations with angels, divinations, and glimpses of heaven and hell; the accounts of visions influenced medieval vision literature, of which they are considered a prototype.

**Fürstenbund** (German: League of Princes), league founded on July 23, 1785, under the leadership of King Frederick II the Great of Prussia to preserve the status quo among the several German states and curb the ambitions in Germany of Emperor Joseph II. It represented the final phase of the conflict between Frederick and the Austrian Habsburgs. Earlier, Frederick had thwarted Joseph's plan to annex Bavaria (in the War of the Bavarian Succession, 1778–79); but in the early 1780s, Joseph renewed his attempts. Frederick was able to persuade other princes—of Saxony, Hanover, and later Saxe-Weimar, Saxe-Gotha, Palatinate-Zweibrücken, Brunswick, Baden, Hesse-Kassel, Anhalt, Ansbach, Mecklenburg, the electorate of Mainz, and other lesser states—to join a league in opposition to Joseph. Joseph was daunted and dropped his Bavarian designs rather than risk another military defeat at the hands of Prussia. Though only temporary, the league represented the first organization of German states headed by Prussia, the state that later unified Germany.

Articles are alphabetized word by word,  
not letter by letter

**Fürstenwalde**, city, Brandenburg Land (state), eastern Germany, on the Spree River near its junction with the Oder-Spree Canal, east of Berlin. Founded between 1252 and 1258 by the margraves of Brandenburg and chartered in 1285, it was the seat of the bishops of Lebus from 1385 to 1571. The cathedral, begun in 1446, was destroyed in 1945. Fürstenwalde's largest enterprise is the nationally owned tire plant; chemicals, metal products, textiles, vehicles, and shoes are also manufactured. Schools for chemical engineering and rubber technology are located there. Pop. (1989 est.) 35,973.

**Fürth**, city, Bavaria Land (state), south-central Germany, situated at the junction of the Pegnitz and Rednitz rivers (which there form the Regnitz), just northwest of Nürnberg. It was originally a Franconian settlement dating from the mid-8th century. The royal palace of Furti (the "Furt") was first mentioned in 1007, when the village was assigned to the newly formed bishopric of Bamberg. In the following centuries both the margraves of Ansbach and the imperial city of Nürnberg claimed seigniorial rights over Fürth. Largely destroyed in the Thirty Years' War (1618–48), the town passed to Bavaria in 1806 and was chartered in 1808. The town hall (1840–50)

and the 12th- and 14th-century St. Michael's Church are notable.

The Fürth-Nürnberg line (the Ludwigsbahn, 1835) was the first railway in Germany, and Fürth now has a port on the Rhine-Main-Danube Canal. Formerly a centre of the gold-beaters' craft, it still produces gold leaf and beaten metals and aluminum and bronze powders. Other products include glassware, toys, optical instruments, furs, and clothes. Pop. (1989 est.) 98,832.

**Furtwangen**, city, Baden-Württemberg Land (state), southwestern Germany, in the upper valley of the Breg River, in the Black Forest (Schwarzwald), northeast of Freiburg im Breisgau. First mentioned in 1179, it was a possession of the abbey of St. George until it passed to Baden in 1806. It was chartered in 1873. Furtwangen has been a centre of the Black Forest clock industry since 1740 and has a clock museum. The city, at an altitude of 2,887 ft (880 m), is also a climatic health and winter resort. Pop. (1989 est.) 9,794.

**Furtwängler, Adolf** (b. June 30, 1853, Freiburg im Breisgau, Baden [Germany]—d. Oct. 10, 1907, Athens, Greece), German archaeologist whose catalogs of ancient Greek sculpture, vase painting, and gems brought thousands of art works into historical order.

In 1878–79 Furtwängler took part in the German excavation of Olympia, site of the ancient Greek games. While serving as museum director for the Berlin Antiquarium (1880–94), he prepared a comprehensive description of Mycenaean vases and pottery fragments from the Aegean area, as well as *Meisterwerke der griechischen Plastik* (1893; *Masterpieces of Greek Sculpture*, 1895).

After becoming professor of archaeology at the University of Munich (1894), he researched the marble sculptures from the Greek island of Aegina and in 1901 went there to begin a systematic excavation of the 5th-century-BC temple of the goddess Aphaea. During his stay he also explored the site of the city of Orchomenus in the ancient district of Boeotia and found evidence of pre-Mycenaean history.

**Furtwängler, (Gustav Heinrich Ernst Martin) Wilhelm** (b. Jan. 25, 1886, Berlin—d. Nov. 30, 1954, near Baden-Baden, W. Ger.), German conductor, one of the great exponents of Romantic music. Known for his passionate, romantic style, he excelled in the works of Beethoven and Wagner.

The son of archaeologist Adolf Furtwängler, he studied in Munich, where he was assistant to the conductor Felix Mottl (1907–09). He became director of the Mannheim Opera in 1915 and in 1920 succeeded Richard Strauss

Wilhelm Furtwängler  
Suddeutscher Verlag

as conductor of the Berlin Opera concerts. In 1922 he followed Arthur Nikisch as conductor of the Gewandhaus Concerts in Leipzig. Other appointments included the directorships of the Berlin Philharmonic Orchestra (1922), the Vienna Philharmonic Orchestra (1930), the

Bayreuth Festivals (1931–32), and the Berlin State Opera (1933). He subsequently toured Europe and England with the Berlin Philharmonic Orchestra.

Furtwängler conducted in Germany during most of the Nazi regime. Although he was offered and accepted the post as conductor of the New York Philharmonic in 1936, public hostility to his alleged Nazi associations caused him to resign. Public sentiment again caused the cancellation of a 1949 appointment as conductor of the Chicago Symphony Orchestra, although he had been formally exonerated of accusations of Nazi complicity.

**Furuta Oribe**, original name FURUTA SHIGENARI (b. 1544, Mino province [now in Gifu prefecture], Japan—d. July 6, 1615, Kyōto), distinguished figure in the history of the Japanese tea ceremony.

After serving as a soldier Oribe was made a daimyo (feudal lord) and placed in charge of the Fushimi Castle in Kyōto. There he became the favourite pupil of the famous tea master Sen Rikyū and, after Rikyū's death in 1591, the foremost tea master in Japan. In 1615, however, Oribe was implicated in a conspiracy against Tokugawa Ieyasu and was forced to commit suicide.

Oribe's influence on the tea ceremony and associated arts extended to teahouse architecture, tea-garden landscaping, and flower arrangement. He is said to have guided the production of pottery at the Bizen kilns in the district of Seto. From his active interest in pottery comes the term *Oribe yaki* ("Oribe ware"), denoting the type of pottery he preferred to use in his tea ceremony: a simple rustic tea bowl with an irregular shape, thick glaze, and soft monochromatic colour.

**Fury**, plural FURIES, Latin FURIA, plural FURIAE, Greek ERINYES, plural ERINYES, also called EUMENES ("Kind One"), plural EUMENIDES, in Greco-Roman mythology, one of a group of goddesses of vengeance. They were probably personified curses but possibly were originally conceived of as ghosts of the murdered. According to the Greek poet Hesiod they were the daughters of Gaea (Earth) and sprang from the blood of her mutilated spouse Uranus; in the plays of Aeschylus they were the daughters of Nyx; in those of Sophocles, they were the daughters of Darkness and of Gaea. Euripides was the first to speak of them as three in number. Later writers named them Alecto ("Unceasing in Anger"), Tisiphone ("Avenger of Murder"), and Megaera ("Jealous"). They lived in the underworld and ascended to earth to pursue the wicked. Being deities of the underworld, they were often identified with spirits of the fertility of the earth. Because the Greeks feared to utter the dreaded name Erinyes, the goddesses were often addressed by the euphemistic names Eumenides ("Kind Ones"), or Semnai Theai ("Venerable Goddesses").

**Fusarium wilt**, also called YELLOWS, widespread plant disease caused by many forms of the soil-inhabiting fungus *Fusarium oxysporum*. Several hundred plant species are susceptible at soil temperatures above 75° F (24° C). Infected plants are usually stunted; their leaves turn pale green to golden yellow and later wilt, wither, die, and drop off progressively upward from the stem base. Dark streaks occur in vascular tissue (xylem) of the roots and lower stem, while roots may decay and seedlings sometimes wilt and die. *Fusaria* can live indefinitely in soil without access to living host plants.

**Fusaro, Lake of**, Italian LAGO DEL FUSARO, coastal lagoon in Napoli *provincia*, Campania *regione*, southern Italy, west of Naples. The lagoon is separated from the sea on the west by

sand dunes. As the ancient Palus Acherusia ("Acherusian Swamp"), it may have been the harbour of nearby Cumae in antiquity. In the first century AD, an outlet was dug at its southern end, with a tunnel under the hill of Torre Gaveta; another outlet was dug in 1858–59. On the hill are the remains of a large villa, probably that of the Roman statesman Servilius Vatia.

**fuse**, in electrical engineering, a safety device that protects electrical circuits from the effects of excessive currents. A fuse commonly consists of a current-conducting strip or wire of easily fusible metal that melts, and thus interrupts the circuit of which it is a part, whenever that circuit is made to carry a current larger than that for which it is intended. The screw-plug fuse was once commonly used in domestic electrical systems. It contains a short bit of wire (the fusible element) enclosed in a fireproof container that has a screw-threaded base; the wire is connected to metal terminals at both the screw base and at the side, and the whole is covered with a transparent glass or mica window for seeing whether the fuse has melted. The cartridge fuse, a type of fuse widely used in industry where high currents are involved, has a fusible element connected between metal terminals at either end of a cylindrical insulating tube.

**fuse**, also spelled FUZE, in explosives technology, device for firing explosives in blasting operations, in fireworks, and in military projectiles.

The blasting safety fuse, employed to fire an explosive from a distance or after a delay, is a hollow cord filled with a mixture resembling black powder and designed to propagate burning at a slow and steady rate. The far end of the fuse is usually embedded in the explosive charge. Detonating cord, also called Cordeau and Primacord, is a hollow cord filled with an explosive material. It is fired by a detonator and is capable of initiating the detonation of certain other explosives at any number of points and in any desired pattern.

The United States and some other military forces have adopted the "z" spelling for the device in ordnance munitions; the fuze sets off the munition, regulates its functioning, and causes it to perform only under predetermined conditions. It is distinct from the primer or firing pin that initiates the launching of a rocket or artillery shell. Impact fuzes function as they hit the target. Time fuzes delay the functioning for a certain period from the starting time. Command fuzes function on signal from a remote-control point. Proximity fuzes function when the munitions carrying them approach to within a given distance of the target. Inferential fuzes infer that a target is nearby if certain conditions are present.

**fusel oil**, a mixture of volatile, oily liquids produced in small amounts during alcoholic fermentation. A typical fusel oil contains 60–70 percent of amyl alcohol (*q.v.*), smaller amounts of *n*-propyl and isobutyl alcohols, and traces of other components. Before industrial production of synthetic amyl alcohols began in the 1920s, fusel oil was the only commercial source of these compounds, which are major ingredients of lacquer solvents. The fusel oil alcohols are apparently produced during fermentation from amino acids. In industrial alcohol plants, fusel oil and ethyl alcohol are recovered from the fermented liquors and separated by distillation. In the beverage industry, fusel oil is ordinarily allowed to remain in the finished products. The amount present in a 100 proof distilled alcoholic beverage is typically between 0.5 and 2 grams per litre (0.07 and 0.3 ounce per gallon).

**fuselage**, central portion of the body of an airplane, designed to accommodate the crew, passengers, and cargo. It varies greatly in design and size according to the function of the

aircraft. In a jet fighter the fuselage consists of a cockpit large enough only for the controls and pilot, but in a jet airliner it includes a much larger cockpit as well as a cabin that has separate decks for passengers and cargo. The predominant types of fuselage structures are the monocoque (*i.e.*, kind of construction in which the outer skin bears a major part or all of the stresses) and semimonocoque. These structures provide better strength-to-weight ratios for the fuselage covering than the truss-type construction used in earlier planes.

**Fuseli, Henry**, original name JOHANN HEINRICH FÜSSLI (b. Feb. 7, 1741, Zürich, Switz.—d. April 16, 1825, Putney Hill, London, Eng.), Swiss-born painter whose works are among the most exotic, original, and sensual pieces of his time.

Fuseli was reared in an intellectual and artistic milieu and initially studied theology. Obligated to flee Zürich because of political entanglements, he went first to Berlin, and then settled in London in 1764. He was encouraged to become a painter by Sir Joshua Reynolds, and he left England in 1768 to study in Italy until 1778. During his stay in Rome he studied the works of Michelangelo and classical art, which became his major stylistic influences; his subject matter was chiefly literary. Fuseli is famous for his paintings and drawings of nude figures caught in strained and violent poses suggestive of intense emotion. He also had a penchant for inventing macabre fantasies, such as that in "The Nightmare" (1781). He had a noticeable influence on the style of his younger contemporary, William Blake.

In 1788 Fuseli was elected an associate of the Royal Academy, becoming a full academician two years later. During 1799–1805 and again from 1810 he was professor of painting at the Royal Academy. He was appointed keeper of the Academy in 1804.

**fusion**: *see* nuclear fusion.

**fusion reactor**, also called THERMONUCLEAR REACTOR, a device that produces electrical power from the energy released in a nuclear fusion reaction.

A brief treatment of fusion reactors follows. For full treatment, *see* MACROPAEDIA: Energy Conversion.

A fusion reaction occurs when two lighter atomic nuclei combine to form the nucleus of a heavier element. When the two nuclei fuse, a small amount of mass is converted into a large amount of energy. For a fusion reaction to occur, the two nuclei must be moving at high speed in order for their mutual electrical repulsion to be overcome. Extremely high temperatures are used to impart these high speeds to the nuclei. In all current designs, the core of a fusion reactor is a hot, dense plasma—*i.e.*, an ionized gas consisting of free nuclei and free electrons. Deuterium and tritium nuclei (heavy hydrogen), being the easiest nuclei to fuse, are the fuel for the reactor.

The chief engineering challenge in producing fusion energy is to produce and confine a plasma at the necessary 100,000,000° C. The most successful approach is to hold a doughnut-shaped plasma together with a magnetic field, a method called magnetic confinement. The fusion of deuterium and tritium produces a helium nucleus (alpha particle) and a neutron. The neutron bombards and heats up the surrounding structure; this heat is then converted to electricity by conventional means (such as a turbine). An alternative approach is to focus an array of powerful lasers on a tiny frozen pellet made of deuterium and tritium. The pellet is compressed by laser energy to very high density; the resultant high temperature is sufficient to produce fusion reactions, and the pellet, now a dense plasma, is burned up in a microexplosion. This method is called inertial confinement, since the plasma is confined only by its own inertia.

Fusion research began in the 1950s. Since that time the efficiency of magnetic confinement fusion reactors has increased a million-fold. In 1994 the Tokamak Fusion Test Reactor at Princeton University generated 10 million watts of fusion power for one second. In the late 20th century an international experiment called the International Thermonuclear Experimental Reactor, or ITER, was designed to generate 1.5 billion watts of fusion power continuously. This experiment, with an estimated cost of \$10 billion, was a partnership between the European Union, Japan, Russia, and the United States and was scheduled to begin construction in 1998. Substantial research is still needed to achieve commercial fusion power, which is not expected to be realized earlier than the middle of the 21st century.

A primary motivation for research in this field lies in the fact that fusion is environmentally clean, generating no pollutants or greenhouse gases and little radioactivity by comparison with fission-reaction nuclear power plants. A fusion reactor would also be safe, with no analog to the fission meltdown. If one of the reactor control systems fails, the plasma simply cools down and the reactions cease. And because deuterium is abundant in the oceans and tritium can be bred in the reactor, fusion reactors could prove a virtually inexhaustible source of energy for humanity.

**Füssen**, city, Bavaria *Land* (state), extreme southern Germany. It lies along the Lech River, at the east foot of the Allgäu Alps, near the Austrian border. The site of a Roman frontier station, the city developed

Neuschwanstein, near Füssen, Ger.  
Devaney Stock • photos Inc

around the Benedictine abbey of St. Magnus (founded 628) and was chartered about 1294. A treaty concluded there in 1745 led to the withdrawal of Bavaria from the War of the Austrian Succession. The small sulfur spa of Faulenbach was incorporated with Füssen in 1921. St. Magnus abbey and church, in their present form, date from 1701 to 1917, although the church has a Romanesque crypt. Other notable landmarks include Hohes Castle (1270–1505; the former summer residence of the prince-bishops of Augsburg) and several Baroque churches. The turreted castles of Hohenschwangau, high above the Schwansee (Swan Lake), and Neuschwanstein, overlooking Pöllat Gorge, are nearby.

A tourist resort, winter sports centre, and customs station, Füssen manufactures clothing and cordage. Pop. (1994 est.) 13,954.

**Füssli, Johann Heinrich:** see Fuseli, Henry.

**Fust, Johann** (b. c. 1400, Mainz [Germany]—d. Oct. 30, 1466, Paris, France), early German printer, financial backer of Johann Gutenberg (the inventor of printing in Europe), and founder, with Peter Schoeffer, of the first commercially successful printing firm.

Fust, a prominent goldsmith, lent Gutenberg 800 guilders in 1450 to perfect his movable-type printing process. An additional 800 guilders was lent about two years later. Gutenberg's 42-line Bible and his 1457 Psalter were almost finished, but Fust sued in 1455 for 2,026 guilders to recover his money with interest. The court found in Fust's favour, and Gutenberg lost his invention and equipment.

With Schoeffer, who was one of Fust's witnesses in the lawsuit, Fust set up his own printing firm and published the 42-line Bible in 1456. The Psalter, the first example of colour printing, with superb red-ink printing and two-colour initials, was finished in 1457. Fust's firm published further works, notably a Benedictine Psalter (1459), Clement V's *Constitutiones*, or *Clementinae* (1460), the 48-line Bible (1462), and Cicero's *De officiis* (1465), the first classical text ever printed.

**Fustât, Al-**, also spelled AL-FOSTAT, capital of the Muslim province of Egypt during the Umayyad and 'Abbâsîd caliphates and under succeeding dynasties, until captured by the Fâtîmid general Jawhar in 969. Founded in 641 by the Muslim conqueror of Egypt, 'Amr ibn al-'Âs, on the east bank of the Nile River, south of modern Cairo, Al-Fustât was the earliest Arab settlement in Egypt and site of the province's first mosque, Jâmi' 'Amr. It grew into a permanent city out of an Arab camp set up for the siege of the Byzantine fortress of Babylon, but it developed rather chaotically. Around a core of permanent structures—mosques, palaces, and administrative offices—grew up a vast confusion of houses and huts, sited to no plan and periodically ravaged by fire and pestilence. The 'Abbâsîd governors thus chose to reside in a northern suburb, Al-'Askar, while the Tûlûnid dynasty built a new quarter, Al-Qatâ'i', to serve as its capital. The city's prosperity, derived from a lively commerce and a fine glassware and ceramics industry, facilitated Al-Fustât's survival after 969, when nearby Cairo became the capital of Fâtîmid Egypt. In 1168 the town, which had never been fortified, was destroyed by fire to prevent its capture by Frankish armies. It was rebuilt a few years later by Saladin, who joined it with Cairo. The city's very name was gradually replaced by that of Al-Qâhîrah (Cairo). In modern Egypt it constitutes a quarter of Cairo known as Maṣr al-'Atîqah ("Old Cairo").

**Fustât ware**, in Islâmic ceramics, style of pottery originating from al-Fustât (now part of Cairo), where, however, many deposits of imported ware have also been found. Its characteristic qualities are poorish white glaze and excellent lustre pigment varying from lemon to intense copper in colour. Some important pieces are incised and covered with transparent glaze.

**Fustel de Coulanges, Numa Denis** (b. March 18, 1830, Paris, France—d. Sept. 12, 1889, Massy), French historian, the originator of the scientific approach to the study of history in France.

After studying at the École Normale Supérieure, he was sent to the French school at Athens in 1853 and directed some excavations at Chios. From 1860 to 1870 he was professor of history at the faculty of letters at the University of Strasbourg, where he had a brilliant career as a teacher. His subsequent appointments included a lectureship at the École Normale Supérieure in February 1870, a professorship at the University of Paris faculty of letters in 1875, the chair of medieval history at the Sorbonne in 1878, and the directorship of the École Normale in 1880.

Fustel's historical thought had two main tenets: the importance of complete objectivity and the unreliability of secondary sources. By his teaching and example he thus established the modern idea of historical impartiality at a time when few people had any qualms about

combining the careers of historian and politician. His insistence on the use of contemporary documents led to the very full use of the French national archives in the 19th century. Fustel, however, was no paleographer, and his fondness for manuscript sources was occasionally responsible for major errors of judgment.

Apart from *La Cité antique* (1864; "The Ancient City"), a study of the part played by religion in the political and social evolution of Greece and Rome, most of Fustel's work was related to the study of the political institutions of Roman Gaul and the Germanic invasions of the Roman empire.

**fustian**, fabric originally made by weaving two sets of cotton wefts, or fillings, on a linen warp, popular during the European Middle Ages. The word has come to denote a class of heavy cotton fabrics, some of which have pile surfaces, including moleskin, velveteen, and corduroy.

Fustian probably originated in Al-Fustât, now part of Cairo, about AD 200, and eventually spread to Spain and Italy, where there were guilds of fustian weavers in the 13th century. As the material became popular its production spread northward; southern Germany and Switzerland had a rising fustian industry in the 14th century, and French weavers were making fringed and roughened fustians in the 16th. These early fustians appear to have been smooth fabrics with a soft raised nap; eventually, a ribbed pile surface was developed. By the 19th century cotton was being used for the warp as well as the filling.

In all fustians one of the sets of filling yarns is made up of floats (yarns that skip over two or more adjacent warp yarns). When a pile fabric is desired, the weft floats must be cut, a process originally performed by hand with a fustian knife but now done mechanically. The pile is brushed, sheared, and singed, and finally the fabric is bleached and dyed.

**fustic**, either of two natural dyes. Old fustic, or yellowwood, is derived from the heartwood of dyer's mulberry, a large, tropical American tree (*Chlorophora tinctoria*, or *Maclura tinctoria*) of the mulberry family, Moraceae. The dye produces yellows on wool mordanted (fixed) with chromium salts.

The dye termed young fustic (zante fustic, or Venetian sumac) is derived from the wood of the smoke tree (*Cotinus coggygria*, or *Rhus cotinus*), a southern European and Asian shrub of the cashew family, Anacardiaceae. Both old and new fustic have been displaced from commercial importance by synthetic dyes.

**Fusulina**, genus of extinct fusulinid foraminiferans (protozoans with a shell) found as fossils in marine rocks of Late Carboniferous age (286 to 320 million years old). *Fusulina*, an excellent index fossil for Late Carboniferous rocks, enables widely separated rocks to be correlated.

**Fusulinella**, genus of extinct fusulinid foraminiferans (protozoans with a shell) found as fossils in Late Carboniferous marine rocks (those formed between 320 and 286 million years ago). Because of its narrow time range and wide geographic distribution, *Fusulinella* is an excellent guide fossil for Late Carboniferous rocks and time.

**fusulinid**, any of a large group of extinct foraminiferans (single-celled organisms related to the modern amoebas but having complex shells that are easily preserved as fossils). The fusulinids first appeared late in the Early Carboniferous Epoch, which ended 320 million years ago, and persisted until the end of the Permian Period, 245 million years ago. Where they occur, the fusulinids have proven to be extremely useful for correlating different rock

units in widely separated regions and for dividing geologic time into smaller units. Petroleum geologists also use them as keys to the locations of economically important deposits of oil and natural gas. Many forms of fusulinids are known, from barely visible species to forms that are easily seen with the naked eye and may be as much as 5 cm (2 inches) long. Many fusulinids resemble grains of wheat; the internal structure, however, is very complex and distinctive. The shell consists of a series of chambers formed about a central longitudinal axis. Complex patterns in the number and arrangement of internal walls and deposits are present and aid in classification and the working out of evolutionary relationships. Most fusulinids lived in clear marine water far from the shore.

**Futa Jallon** (Guinea): see Fouta Djallon.

**Futabatei Shimei**, pseudonym of HASEGAWA TATSUNOSUKE (b. April 4, 1864, Edo [now Tokyo], Japan—d. May 10, 1909, at sea in Bay of Bengal), Japanese novelist and translator of Russian literature; his *Ukigumo* (1887–89; "The Drifting Clouds," translated, with a study of his life and career, by M. Ryan as *Japan's First Modern Novel: Ukigumo of Futabatei Shimei*, 1967) brought modern realism to the Japanese novel.

Although Futabatei wrote three novels and translated many stories, he is best known for *Ukigumo*, his first novel, and for his earliest translations of stories by the Russian writer Ivan Turgenev, *Aibiki* ("The Rendezvous") and *Meguriai* ("Chance Meetings"), both published in 1888. In these works Futabatei used a style called *gembun itchi* (unification of spoken and written language), one of the first attempts to replace classical Japanese literary language and syntax with the modern colloquial idiom.

Born to an aristocratic samurai family, Futabatei studied Russian at the Tokyo School of Foreign Languages (1881–86), where he became interested particularly in Ivan Goncharov, Fyodor Dostoyevsky, Turgenev, and Vissarion Belinsky. He began his literary career soon after leaving school, with the help of the critic, novelist, and translator Tsubouchi Shōyō. *Ukigumo*, a story in which an ineffectual idealist loses out in the rude world of rapidly modernizing late 19th-century Japan, and Futabatei's translations of fiction were well received. Futabatei, however, was displeased with his novel and in need of money, so in 1889 he joined the staff of the government gazette *Kampō*, where he remained until 1897. He did not write another novel for nearly 10 years. From 1898 to 1902 he taught Russian and worked for government agencies, later going to Harbin and Peking in China. After returning to Japan in 1903, he resumed translating fiction professionally and in 1904 became the Tokyo correspondent for the *Ōsaka Asahi* newspaper. Between 1896 and 1909 his output included translations of stories by Turgenev, Nikolay Gogol, Leo Tolstoy, and Maksim Gorky; articles on Esperanto, literary criticism, and social conditions; and two novels, *Sono omokage* (1906; *An Adopted Husband*) and *Heibon* (1907; *Mediocrity*). In 1908 Futabatei traveled to Russia as a correspondent for the *Asahi* but fell ill and died en route from Russia to Japan.

**futhark** (writing system): see runic alphabet.

**Futuna Islands**: see Horne Islands.

**futures**, commercial contract calling for the purchase or sale of specified quantities of a commodity at specified future dates. The origin of futures contracts was in trade in agricultural commodities, and the term commodity is used to define the underlying asset even

though the contract is frequently completely divorced from the product. It therefore differs from a simple forward purchase or sale in the cash market, which involves actual delivery of the commodity at the agreed time in the future.

A brief treatment of futures follows. For full treatment, see MACROPAEDIA: Markets.

The common characteristics of futures markets are that they can be made in any commodity that enters into trade on a scale large enough to provide the necessary liquidity, that is available to a broadly standard specification, and that is traded in free market conditions that allow price fluctuations based on the interplay of supply and demand factors and that preclude dominant producers from controlling the market. A futures contract represents a binding agreement to buy a commodity at a specified price on a specified future date. Thus it is possible for a trader to obtain a guarantee for the price he will have to pay for a commodity in the future. A market is made in futures contracts, involving trading in the obligations inherent in the contracts.

Futures developed originally to provide cheap forms of banking and insurance. Farmers in the United States, for example, were able to sell their harvest in advance on the Chicago commodity futures markets at a lower dealing cost than the interest rates charged by the banks. More recently, financial futures have extended the same principle by providing protection for the investor or businessman against changes in interest rates, allowing him to fix the cost today of raising debt that he knows he will need tomorrow when interest rates may have become unfavourable. Bankers and financiers can also use futures to insure against changes in interest rates and currency exchange rates. Futures contracts have been common in the markets for agricultural commodities for a very long period, but it was only in 1972 that financial futures, which treat money as simply a commodity, developed in Chicago, the home of agricultural futures.

There are two basic types of traders in a futures market: hedgers and speculators. Both are necessary to the market in order to generate a sufficient volume of two-way business. Hedgers seek to avoid or minimize the financial risks associated with their current commercial activity by in effect taking out an insurance policy in the shape of a futures contract against adverse price or interest-rate movements. On the other hand, the speculator, in the expectation of making a profit, seeks risk by committing his funds to back his own view of higher or lower prices or interest rates. It is the speculators who supply the necessary liquidity to the futures markets and are instrumental in allowing buyers to be matched with sellers, although the actual contracts are made through the market's central clearinghouse. It is the intervention of the clearinghouse that removes the credit risk and permits standardization of contracts to allow easy buying and selling.

**Futurism**, Italian FUTURISMO, Russian FUTURISM, an early 20th-century artistic movement that centred in Italy and emphasized the dynamism, speed, energy, and power of the machine and the vitality, change, and restlessness of modern life in general. The most significant results of the movement were in the visual arts and poetry.

Futurism was first announced on Feb. 20, 1909, when the Paris newspaper *Le Figaro* published a manifesto by the Italian poet and editor Filippo Tommaso Marinetti (*q.v.*). The name Futurism, coined by Marinetti, reflected his emphasis on discarding what he conceived to be the static and irrelevant art of the past and celebrating change, originality, and innovation in culture and society. Marinetti's manifesto glorified the new technology of the automobile and the beauty of its speed, power,

and movement. He exalted violence and conflict and called for the sweeping repudiation of traditional cultural, social, and political values and the destruction of such cultural institutions as museums and libraries. The manifesto's rhetoric was passionately bombastic; its tone was aggressive and inflammatory and was purposely intended to inspire public anger and amazement, to arouse controversy, and to attract widespread attention.

**Painting and sculpture.** With the support of Marinetti, the painters Umberto Boccioni, Carlo Carrà, Luigi Russolo, Giacomo Balla, and Gino Severini published several manifestos on painting in 1910. Like Marinetti, they glorified originality for its own sake and despised inherited traditions of art. Although they were not as yet working in what was to become the Futurist style, they began to emphasize an emotional involvement in the dynamics of modern life, and toward this end they called for rendering the perception of movement and communicating to the viewer the sensations of speed and change. To achieve this, the Futurist painters adopted the Cubist technique of depicting several sides and views of an object simultaneously by means of fragmented and interpenetrating plane surfaces and outlines. But the Futurists additionally sought to portray the object's movement in space, and they tried to achieve this goal by rhythmic spatial repetitions of the object's outlines during its transit, producing an effect akin to that obtained by making multiple and sequential photographic exposures of a moving object. The Futurist paintings differed from Cubist ones in other important ways. While the Cubists favoured still life and portraiture, the Futurists preferred such subjects as speeding automobiles and trains, racing cyclists, dancers, animals, and urban crowds in movement. The resulting paintings had brighter and more vibrant colours than Cubist ones and revealed dynamic, agitated compositions in which rhythmically swirling forms reached crescendos of violent movement.

Boccioni also became interested in sculpture, publishing a manifesto on the subject in the spring of 1912. Soon afterward, he began working in this medium, creating the highly original "Development of a Bottle in Space" (1912) and "Unique Forms of Continuity in Space" (1913). Antonio Sant'Elia formulated a Futurist manifesto on architecture in 1914. His visionary drawings of highly mechanized cities and boldly modern skyscrapers of the future prefigure some of the most imaginative 20th-century architectural planning. Sant'Elia was killed in action in 1916 during World War I, however.

Boccioni, who had been the most talented artist in the group, also died during military service in 1916. This event, combined with dilution of the group's daring as a result of expansion of its personnel and the coming of war, brought an end to the Futurist movement as an important historical force in the visual arts.

**Literature.** After his initial broad manifesto of 1909, Marinetti wrote or had a hand in creating a whole series of manifestos dealing with poetry, the theatre, architecture, and other arts. He founded the journal *Poesia* at Paris in 1905, and he later founded a press with the same name to publish their works. On proselytizing visits to England, France, Germany, and Russia, Marinetti influenced the work of the English founder of Vorticism, Wyndham Lewis, and the poet Guillaume Apollinaire.

In Russia the Marinetti visit took root in a kind of Russian Futurism that went beyond its Italian model in a revolutionary social and political outlook. Marinetti influenced the two Russian writers considered the founders of Russian Futurism, Velemir Khlebnikov (*q.v.*), who remained a poet and a mystic, and the younger Vladimir Mayakovsky (*q.v.*), who became "the poet of the Revolution" and the

popular spokesman of his generation. The Russians published their own manifesto in December 1912, entitled *A Slap in the Face of Public Taste*, which echoed the Italian manifesto of the previous May. The Russian Futurists advocated the abandonment of Aleksandr Pushkin, Fyodor Dostoyevsky, and Leo Tolstoy and of then-current Russian symbolist verse and called for the creation of new and experimental techniques of writing poetry. Both the Russian and the Italian Futurist poets discarded logical sentence construction and traditional grammar and syntax. Futurist poetry frequently presented an incoherent and anarchic blend of words stripped of their meaning and used for their sound alone. As the first group of artists to identify wholeheartedly with the Bolshevik Revolution of 1917, the Futurists sought to dominate post-Revolutionary culture and create a new art that would be integrated into all aspects of daily life of a revolutionary culture. They were favoured by Anatoly Lunacharsky, the first Soviet commissar of education, and given important cultural posts. But the Russian Futurists' challenging literary techniques and their theoretical premises of revolt and innovation proved too unstable a foundation upon which to build a broader literary movement. The Futurists' influence was negligible by the time of Mayakovsky's death in 1930.

**futurology**, in the social sciences, the study of current trends in order to forecast future developments. While the speculative and descriptive aspects of futurology are traceable to the traditions of utopian literature and science fiction, the methodology of the field originated in the "technological forecasting" developed near the end of World War II, of which *Toward New Horizons* (1947) by Theodore von Kármán is an important example.

At the RAND Corporation in California during the 1950s, Herman Kahn and others pioneered the so-called scenario technique for analyzing the relationship between weapons development and military strategy. Later Kahn applied this technique in *On Thermonuclear War* (1960), a book that examines the potential consequences of a nuclear conflict. During the time of Kahn's first studies, the mathematician Olaf Helmer, also at RAND, proposed a theoretical basis for the use of expert opinion in forecasting.

In 1964 the French social scientist Bertrand de Jouvenel published *L'Art de la conjecture* (*The Art of Conjecture*), in which he offered a systematic philosophical rationale for the field. The following year the American Academy of Arts and Sciences formed its Commission on the Year 2000 "to anticipate social patterns, to design new institutions, and to propose alternative programs"; the commission's 1967 report constituted the first wide-ranging futurological study in the United States.

The field was brought to wide popular attention in 1972 when Dennis Meadows and colleagues at the Massachusetts Institute of Technology published *The Limits to Growth*, based on a study commissioned by the Club of Rome, an international assembly of business leaders. This report focused on hypotheses derived from a computer model of the interaction of various global socioeconomic trends; it projected a Malthusian vision in which the collapse of world order would result if population growth, industrial expansion, and increased pollution, combined with insufficient food production and the depletion of natural resources, were to continue at current rates. To offset these trends, the report called for "a Copernican revolution of the mind," to reevaluate the belief in endless growth and the tacit acceptance of wastefulness. Besides zero population growth and a leveling-off of industrial production, the report also recommended increased pollution control, the recycling of materials, the manufacture of more durable and

repairable goods, and a shift from consumer goods to a more service-oriented economy. The U.S. government-commissioned *Global 2000 Report to the President* (1981) reiterated many of these concerns.

Criticism of these and other studies has centred mainly on the limitations of models and the subjective, interpretive nature of projections based on them. Futurologists generally acknowledge these difficulties but emphasize the increasing sophistication of their analytic techniques, which draw from such fields as mathematics, economics, environmental research, and computer science.

Other notable basic works in futurology include *Future Shock* (1970) by Alvin Toffler, *The Coming of Post-Industrial Society* (1973) by Daniel Bell, *The Fate of the Earth* (1982) by Jonathan Schell, and *The Green Machines* (1986) by Nigel Calder. (J.O.T./Ed.)

*Where the same name may denote a person, place, or thing, the articles will be found in that order*

**Fux, Johann Joseph** (b. 1660, Hirtenfeld, Styria, Austria—d. Feb. 13, 1741, Vienna), Austrian composer known for his theoretical work on counterpoint, *Gradus ad Parnassum*.

Fux became organist at the Schottenkirche in Vienna in 1696 and court composer to the Holy Roman emperor Leopold I in 1698. In addition, he held the post of chapelmaster at St. Stephen's Cathedral in Vienna (1705-15).

Fux was a prolific composer of vocal and instrumental music. His works include 19 operas, of which *Costanza e fortezza* (1723) is notable; 29 partitas, including the *Concentus musico-instrumentalis* (1701); 10 oratorios; and 50 masses, of which the *Missa canonica*, (1708), written in canon throughout, is particularly admired. His book *Gradus ad Parnassum* (1725; *Steps to Parnassus*) attempted to systematize contrapuntal practices. It was long the standard textbook on counterpoint and was studied by Wolfgang A. Mozart, Joseph Haydn, and other 18th-century composers.

**Fuxin** (China): see Fu-hsin.

**fuze**: see fuse.

**Fuzhou** (China): see Fu-chou.

**Fuzuli, Mehmed bin Süleyman**, Fuzuli also spelled FUDULI (b. c. 1495, Karbalā', Iraq—d. 1556, Karbalā'), Turkish poet and the most outstanding figure in the classical school of Turkish literature.

A resident of Baghdad, Fuzuli apparently came from a family of religious officials and was well versed in the thought of his day, but very little is known about his life. Among his early patrons was Shāh Esmā'il I, founder of the Šafavid dynasty of Iran and conqueror of Baghdad in 1508. Twenty-six years later, when the Ottoman sultan Süleyman I took Baghdad, Fuzuli attempted to curry favour with his new masters and henceforth wrote in the name of the Ottoman sovereign. It seems that he was never able to move to the Ottoman capital Constantinople (Istanbul), however, but remained in Iraq throughout most of his life. He composed his famous *Şikāyet-name* ("Complaint"), in which he caustically commented on not being given the status of court poet in Constantinople. Fuzuli composed poetry with equal facility and elegance in Turkish, Persian, and Arabic. Although his Turkish works are written in the Azerbaijani Azeri dialect, he had a thorough knowledge of both Ottoman and Chagatai Turkish literary traditions.

The works for which he is famous include his melodic and sensitive rendition of the great Muslim classic *Laylā ve Mecnun*. This celebrated allegorical romance depicts the attraction of the Majnūn (the human spirit) for Laylā (divine beauty). Fuzuli is the author

of two *divans* (collections of poems), one in Azerbaijani Turkish and one in Persian. These anthologies contain examples of his most lyrical poetry, many concerned with mystical love and others lamenting the ephemeral nature of this world. His poetic expression, characterized by sincerity, passion, and a pervasive strain of melancholy, transcended the highly formalized classical Islāmic literary aesthetic. Fuzuli's works influenced many poets up to the 19th century.

**fuzzy logic**, in mathematics, a form of logic based on the concept of the fuzzy set. Membership in fuzzy sets is expressed in probabilities or degrees of truth, i.e., as a continuum of values ranging from 0 to 1.

Fuzzy logic and fuzzy sets were first described in the mid-1960s by Lotfi Zadeh. According to fuzzy-logic theorists, classical logic oversimplifies the concept of set membership by flatly including or excluding an individual, whereas fuzzy logic expresses the extent to which an individual pertains to a set. For example, under classical logic, theoretical tree *x* is a member of the set of tall trees; in contrast, under fuzzy logic, *x* pertains partly to the set of tall trees and can be described as fairly tall.

As a form of data processing, fuzzy logic is employed by advanced electronic computer systems. In less complex information processors, the possibility that a particular event will occur is expressed as a certainty (either false or true) represented by the binary digits 0 or 1. Fuzzy-logic systems, in contrast, break down the chance of the occurrence into varying degrees of truthfulness or falsehood (e.g., will occur, probably will occur, might occur, might not occur, etc.). This allows the outcome of an event to be expressed as a probability. Moreover, as additional data is gathered, many fuzzy-logic systems are able to adjust continually the values assigned to different probabilities. Because some fuzzy-logic systems appear able to learn from their mistakes and mimic human thought processes, they are often considered a crude form of artificial intelligence.

Fuzzy-logic systems were considered an experimental technology during the 1980s, but they achieved commercial application in the early 1990s. Advanced clothes-washing machines, for example, use fuzzy-logic systems to detect and adapt to patterns of water movement during a wash cycle. Other applications for fuzzy logic include expert systems, self-regulating industrial controls, and computerized speech and handwriting recognition programs.

**Fw 190**, abbreviation of FOCKE-WULF 190, fighter aircraft of Nazi Germany, second in importance only to the Me 109 (or Bf 109) in that nation's air force during World War II. The Fw 190 was a single-seat fighter that first flew in 1938. After some early technical problems, it went into service in 1941 and was superior to all its opponents until 1942-43; it remained a successful fighter and fighter-bomber until the end of World War II. About 20,000 Fw 190s were manufactured between 1939 and 1945.

The Fw 190 was a low-wing monoplane whose early versions were armed with four 7.9-millimetre machine guns. Two 20-millimetre cannons replaced two of the machine guns in the Fw 190A-2 version, which had a maximum speed of about 660 km (410 miles) per hour and a ceiling of 10,600 m (35,000 feet). The Fw 190F version was specialized for ground attack and had extra armour to protect its pilot, while the Fw 190G was intended as a fighter-bomber and could carry a 1,800-kilogram (3,960-pound) bomb. The Fw 190 was continually improved, and by 1944, the Fw 190A-8 version carried an ar-

mament of four 20-millimetre cannons and two 13-millimetre machine guns. The last operational model was the Fw 190D-9, which entered service in late 1944 and had a top speed of about 690 km (430 miles) per hour.

**FWCC:** see Friends World Committee for Consultation.

**Fyffe, Will** (b. 1885, Dundee, Scot.—d. Dec. 14, 1947, St. Andrews, Fife), Scottish actor, music-hall entertainer, and pantomimist, one of the most popular character comedians of British stage and screen.

Fyffe, 1939

By courtesy of the National Film Archive, London

As a child Fyffe toured Scotland in his father's stock company; he made his debut as Little Willie in *East Lynne*. A precocious actor, he played the aged Polonius in Shakespeare's *Hamlet* when only 15, after which he toured with other companies. Though his ability was considerable, he devoted himself to the music hall, going into revue with his sketches of Scottish characters—the Glasgow drunk, the village idiot, the sailor, the centenarian, the railway guard.

Despite discouragements, Fyffe proved his mastery of the art of comic and of truly pathetic impersonation by reaching top billing when he appeared at the London Pavilion in 1921. During the 1930s he took part in a number of films, notably as the Scottish shepherd in *Owd Bob*. For his tireless services in entertaining troops during World War II, he was appointed Commander of the Order of the British Empire.

**Fylde**, borough and district, county of Lancashire, England. It lies on the north bank of the estuary of the River Ribble at the Irish Sea, below the resort borough of Blackpool. Fylde district is part of the Fylde geographic region, a low coastal plain 18 miles (29 km) wide between the Ribble and Morecambe Bay to the north. It is an area of undulating terrain containing unstratified glacial drift and pockets of marshland, now mostly drained. Extensive sand beaches are found at the resort of Lytham St. Anne's, where the Ribble meets the sea.

In the 18th century, the agricultural produce of the Fylde geographic region won it the epithet "granary of Lancashire." Dairy farming and poultry raising predominate in the contemporary district.

Lytham St. Anne's, built on sand dunes overlooking the sea, is a residential and family resort community with little industry. International golf matches, including the Ryder Cup and the British Open, are sometimes played there. An old windmill and the Jacobean (late 18th-century) Lytham Hall are architectural

features. Kirkham, an old market town in the centre of the district, contains the ruins of an abbey founded in 1125 for Augustinian canons by Walter L'Espece, Henry I's itinerant justice in the north. There is a major British aerospace industry at Warton, and the only plant in the country producing nuclear fuel elements is located at Salwick. Area 64 square miles (165 square km). Pop. (1991 prelim.) 70,100.

**Fyn**, *amtskommune* (county commune), Denmark, comprising 25 inhabited islands between Zealand and the Jutland peninsula. Funen and Langeland (*qq.v.*) are the two largest islands, with more than 90 percent of the population. Odense is the administrative centre and largest city. Road bridges connect the islands of Funen, Tåsinge, and Langeland; Ærø and smaller islands have ferry connections with the rest of the county. Fyn is a fertile agricultural and fruit-growing county. Area 1,346 square miles (3,486 square km). Pop. (1993 est.) 465,239.

**Fyn** (island, Denmark): see Funen.

**Fyodor**, also spelled FĒDOR, FEDOR, or FEODOR, English THEODORE, name of Russian tsars grouped below chronologically and indicated by the symbol •.

• **Fyodor I**, in full FYODOR IVANOVICH (b. May 31, 1557, Moscow, Russia—d. Jan. 7 [Jan. 17, New Style], 1598, Moscow), tsar of Russia (1584–98) whose death ended the rule of the Rurik dynasty in Russia.

The son of Ivan IV the Terrible and his first wife, Anastasiya Romanovna Zakharina-Yureva, Fyodor succeeded his father on March 19, 1584. Being both physically weak and feeble-minded, however, he took no part in government affairs, which were dominated by his wife's brother, Boris Godunov. Godunov was, therefore, responsible for the major achievements of Fyodor's reign—the elevation of the metropolitan see of Russia to a patriarchate (1589), the recovery in 1595 of lands near the Gulf of Finland that had been lost to Sweden in 1583, and the strengthening of Russia's control over western Siberia and territory in the Caucasus. When Fyodor died childless in 1598, the Rurik dynasty became extinct and the throne of Russia was transferred, by vote of a *zemsky sobor* ("assembly of the land"), to Godunov.

• **Fyodor II**, in full FYODOR BORISOVICH GODUNOV (b. 1589—d. June 10 [June 20, New Style], 1605, Moscow, Russia), tsar who ruled Russia briefly (April–June 1605) during the Time of Troubles (1598–1613).

The son of Boris Godunov (reigned 1598–1605), Fyodor received an excellent education and was well acquainted with state affairs when his father unexpectedly died and he ascended the Russian throne (April 13 [April 23], 1605). His rule was immediately challenged, however, by the first False Dmitry, a pretender to the throne, who, claiming to be the son of Ivan IV the Terrible (reigned 1547–84) and the legitimate heir to the throne, had invaded Russia in October 1604 in an effort to overthrow Boris Godunov. After Fyodor's military commander shifted his support to the pretender, Fyodor's mother tried to take power and control the situation. Her action, however, aroused the hostility of the boyars (members of the powerful Russian aristocracy), who provoked a Moscow mob to riot and to murder Fyodor and his mother; immediately afterward the first False Dmitry

entered Moscow and assumed the throne of Russia.

• **Fyodor III**, in full FYODOR ALEKSEYEVICH (b. May 30 [June 9, New Style], 1661, Moscow, Russia—d. April 27 [May 7], 1682, Moscow), tsar of Russia (reigned 1676–82) who fostered the development of Western culture in Russia, thereby making it easier for his successor, Peter I the Great (reigned 1682–1725), to enact widespread reforms based on Western models.

The eldest son of Alexis (reigned 1645–76), Fyodor not only was educated in the traditional subjects of Russian and Church Slavonic but also was tutored in Polish and Latin by Simeon Polotsky, a noted theologian who had studied in Kiev and Poland. When Alexis died, Fyodor ascended the throne (Jan. 19 [Jan. 29], 1676), but his youth and poor health prevented him from actively participating in the conduct of government affairs. His uncle Ivan B. Miloslavsky assumed the dominant position in Fyodor's government at first, but he was soon displaced by two courtiers, I.M. Yazykov and A.T. Likhachev, who shared Fyodor's educational background and who, in spite of objections from the Russian Orthodox clergy, promoted the spread of Polish customs, Roman Catholic religious doctrines, and Latin books among the Russian aristocracy. After 1681 Vasily V. Golitsyn became the most significant figure in Fyodor's administration; under his influence vast military reforms were undertaken, and the system of *meshchestvo*, by which a noble was appointed to a service position on the basis of his family's rank in the hierarchy of boyars, was abolished (1682).

When Fyodor died childless, he was succeeded, after some dispute, by both his brother, Ivan V (coruled 1682–96), and his half-brother, Peter I (coruled 1682–96; reigned alone 1696–1725); his sister Sophia Alekseyevna served as regent for the two young tsars (1682–89).

**fyrd**, tribal militia-like arrangement existing in Anglo-Saxon England from approximately AD 605. Local in character, it imposed military service upon every able-bodied free male. It was probably the duty of the ealderman, or sheriff, to call out and lead the fyrd. Fines imposed for neglecting the fyrd varied with the status of the individual, landholders receiving the heaviest fines and common labourers the lightest. The fyrd was gradually superseded by the gathering of the thanes (feudal lords) and their retainers, but it was occasionally called out for defensive purposes even after the Norman Conquest (1066).

**Fyt, Jan** (b. 1611, Antwerp, Brabant, Spanish Netherlands [now in Belgium]—d. Sept. 11, 1661, Antwerp), Flemish painter known for his technical mastery in the rendering of animals.

Apprenticed to a painter when scarcely more than 10 years old, Fyt was accepted into the Guild of St. Luke as a master at age 20 and over the next 30 years produced a vast number of pictures with facility and power. His forte was the depiction of animal life in its most varied forms; but for human figures and architectural backgrounds he often relied on collaborators. The masterpieces "Silenus Amongst Fruit and Flowers," "Diana and Her Nymphs with the Produce of the Chase," and "Dead Game and Fruit in Front of a Triumphal Arch" represent Fyt's collaborations with three different painters.

**Fyzabad** (India): see Faizābād.

**G metal:** see gunmetal.

**Ga**, also spelled GAN, or GĀ, people of the southeast coast of Ghana, speaking a dialect of the Kwa branch of Niger-Congo languages. The Ga are descended from immigrants who came down the Niger River and across the Volta during the 17th century. The Ga-speaking peoples were organized into six independent towns (Accra, Osu, Labadi, Teshi, Nungua, and Tema). Each town had a stool, which served as the central object of Ga ritual and war magic. Accra became the most prominent Ga town and is now the capital of Ghana.

The original Ga immigrants were farmers, but today fishing and trading in imported goods are the principal occupations. Trading is generally in the hands of women, and a husband has no control over his wife's money. Succession to most offices held by women and inheritance of women's property are by matrilineal descent. Inheritance of other property and succession to male-held public offices are by patrilineal descent. Men of the lineage live together in a men's compound, while women, even after marriage, live with their mothers and children in a women's compound.

Each Ga town has a number of different cults and many gods, and there are a number of annual town festivals.

**Gabar**, any member of the small Zoroastrian minority in Iran. The name Gabar was formerly applied derogatorily to the Iranian Zoroastrians; the term is linguistically related to the Arabic *kāfir*, meaning "infidel." The Zoroastrians who remained in Persia (modern Iran) after the Arab-Muslim conquest (7th century AD) had a long history as outcasts. Although they purchased some toleration by paying the *jizya* (poll tax), not abolished until 1882, they were treated as an inferior race, had to wear distinctive garb, and were not allowed to ride horses or bear arms. They were concentrated in Kermān and Yazd, where Zoroastrians still maintain fire temples. Many also live in Teherān. Long isolated, the Iranian Zoroastrians made contact with the Parsis, the wealthy Zoroastrians of India, in the 15th century, and exchanged messages concerning religious lore. Since the 19th century the Parsis have taken a lively interest in improving the depressed condition of their Iranian coreligionists. They organized a society that raised funds to provide general aid and, especially, facilities for education. With the support of British ambassadors, their representatives remonstrated with the Persian government over discrimination against Zoroastrians. Beginning with the reign of Reza Shah (1921-41), the Iranian Zoroastrians enjoyed wider religious tolerance for decades until the Islāmic revolution of 1978-79. They currently number a few thousand.

**gabardine**, any of several varieties of worsted, cotton, silk, and mixed tightly woven fabrics, embodying certain features in common and chiefly made into suits and overcoats. It is a relatively strong and firm cloth, made with a twill weave, and somewhat resembling whipcord but of lighter texture. The welt, or filling, lies entirely at the back and is therefore not visible from the front, a circumstance that allows the use of filling of inferior quality without loss of durability, for only the warp surface is exposed to wear.

Gabardine was originally a type of waterproofed fabric employed for the manufacture of raincoats. A fabric of a more open and much lighter texture, produced entirely of silk, is called silk, or voile, gabardine.

**gabai** (Hebrew: "collector"), plural GABBAIM, or GABBAIS, treasurer or honorary official of a Jewish Orthodox congregation, often placed in charge of funds used for charity. The office is a carry-over from former times, when men whose reputations were above reproach collected funds for charity. These *gab-*

*ba'e tzedaqa* were so esteemed that no financial reports were ever asked for. The Talmud, nonetheless, insisted that they work in pairs to avoid suspicion of wrongdoing.

Originally, gabbaim were men who gathered taxes for the Roman government. In this capacity their reputation as cheats and scoundrels was so notorious that their testimony was not accepted in Jewish courts of law.

**gabbro**, any of several medium- or coarse-grained rocks that consist primarily of plagioclase feldspar and pyroxene. Essentially, gabbro is the intrusive (plutonic) equivalent of basalt, but whereas basalt is often remarkably homogeneous in mineralogy and composition, gabbros are exceedingly variable. Gabbros are found widely on the Earth and on the Moon as well. Gabbros are sometimes quarried for dimension stone (the black granite of commerce), and the San Marcos Gabbro of southern California is used for gauge blocks, but the

Hornblende gabbro found near Shelby, N.C.  
Benjamin M. Shauh

direct economic value of gabbro is minor. Far more important are the primary mineralizations of nickel, chromium, and platinum that occur almost exclusively in association with gabbroic or related ultrabasic (very silica-poor) rocks. Primary magnetite (iron) and ilmenite (titanium) mineralizations are often intimately associated with gabbroic complexes.

Banded, or layered, gabbroic complexes in which monomineral or bimineral varieties are well developed have been described from Montana, the Bushveld in South Africa, and the island of Skye. There are also gabbro complexes that are locally streaky and inhomogeneous and are not regularly layered, as the large, basinlike intrusion at Sudbury, Ont., and some of the larger diabase sills (tabular intrusions), as at Beaver Bay, Minn.; the Palisades, New Jersey; and many of the Karoo (Karoo) diabases in South Africa.

A lopolith at Duluth, Minn., is a notable exception to the rather arbitrary division between layered and unlayered gabbro complexes. The lower part of this mass has the average composition of an olivine gabbro but is strongly banded, with individual bands that vary in composition from anorthositic to peridotite (monomineralic rocks that contain labradorite and olivine). The upper portion is a comparatively homogeneous feldspathic gabbro, locally patchy and streaky but not sharply banded. Between the two major divisions, and again at the top of the feldspathic gabbro, is a zone of granophyre or micropegmatitic granite.

**Gabelentz, Hans Conon von der** (b. Oct. 13, 1807, Altenburg, Saxe-Gotha-Altenburg [Germany]—d. Sept. 3, 1874, Lemnitz, Ger.), German linguist, ethnologist, and government official who conducted important studies of a large number of languages. He also took some part in political affairs and was prime minister of the duchy of Saxe-Altenburg from 1848 to 1849.

After completing his university studies, Gabelentz did research on the Chinese and Finno-Ugric languages and published *Éléments de la grammaire mandchoue* (1832; "Elements

of Manchu Grammar"). Other works include *Grundzüge der syrjanischen Grammatik* (1841; "Principles of Zyryan Grammar") and an edition, with translation, glossary, and grammar (1843-46), of the 4th-century Gothic Bible of Bishop Ulfilas. He also wrote many papers on Swahili, Samoyed, Formosan, and other languages. His *Beiträge zur Sprachenkunde* (1852; "Contributions to Linguistics") included grammars of Dakota and other little-known languages.

In 1864 he published a Manchu translation, with dictionary, of three Mongolian languages. About this time he was preparing *Die melanesischen Sprachen*... (1860-73; "The Melanesian Languages..."), dealing with the languages of the Fiji, New Hebrides, and other islands of the southwestern Pacific and showing their relation to Indonesian and Polynesian. He reputedly knew 80 languages, 30 of which he spoke fluently.

**Gabelich, Gary** (b. Aug. 29, 1940, Long Beach, Calif., U.S.—d. Jan. 26, 1984, San Pedro, Calif.), American automobile-racing driver who set a world land speed record of 622.407 miles per hour (1,001.67 km/h) on Oct. 23, 1970 (broken by Stan Barrett in 1979).

Gabelich began racing hot-rod cars while he was in high school. In the late 1950s he competed as a drag racer of both automobiles and boats. In 1969 he set a drag-boat record of 200.44 miles per hour (322.38 km/h). He achieved his 1970 land speed record on the Bonneville Salt Flats (Utah) in a rocket-powered, bullet-shaped car.

**gabelle**, form of tax in France before the Revolution of 1789—in particular, from the 15th century onward, the tax on salt.

In the 14th century the gabelle denoted any tax on the sale of consumer goods; an ordinance of 1360 made it a permanent tax. In the 15th century the gabelle began to mean specifically the salt tax, that is, a tax on consumption of salt. The nobility, the clergy, and certain other privileged persons were exempted.

The high rate and unequal distribution of the gabelle provoked widespread contraband dealing in salt by smugglers. The gabelle's unpopularity was forcefully expressed in the lists of grievances drawn up for the Estates-General of 1789 on the eve of the revolution. The gabelle was abolished in March 1790.

**Gaberones** (Botswana): see Gaborone.

**Gabès** (Tunisia): see Qābis.

**Gabes, Gulf of**, Arabic KHALJ QĀBIS, French GOLFE DE GABÈS, Latin SYRTIS MINOR, inlet, on the east coast of Tunisia, northern Africa. It is 60 miles (100 km) long and 60 miles wide and is bounded by the Qarqannah (Kerkena) Islands on the northeast and by Jarbah (Djerba) Island on the southeast. Except for the Strait of Gibraltar and the Gulf of Venice, it is the only part of the Mediterranean with a substantial tidal range (about 8 feet [2½ m] at spring tides), causing the uncovering of extensive sandbanks at low water. Sponge and tuna fisheries are located at the main ports of Qābis (Gabès) and Šafaqis (Sfax). Oil and natural-gas deposits have been found in the gulf, east of Šafaqis.

**gabija**, also spelled GABIETA (Lithuanian), Latvian UGUNŠ MĀTE, Old Prussian PANICKE, in Baltic religion, the domestic hearth fire. In pre-Christian times a holy fire (*šventa ugnis*) was kept in tribal sanctuaries on high hills and riverbanks, where priests guarded it constantly, extinguishing and rekindling it once a year at the midsummer festival. Eventually this tradition was moved into the home as the *gabija*, and its care became the responsibility

of the mistress of the house. Every evening she carefully tended the fire lest it go out, then prayed to it to ensure the family's good fortune. During wedding ceremonies the bride was given a fire from her mother's hearth in order that the *gabija* might provide an auspicious beginning for the new family.

**Gabin, Jean**, original name JEAN-ALEXIS MONCORGÉ (b. May 17, 1904, Paris, Fr.—d. Nov. 15, 1976, Paris), one of the most popular film actors in France from the 1930s to the '60s.

Gabin was the son of a music-hall comedian (stage name Jean Gabin). In 1923 he began a theatrical career in the Folies-Bergère but left the stage after his film debut in *Chacun sa chance* (1931). He achieved fame in *Maria Chapdelaine* (1934) and later in *Pépé le Moko* (1937), directed by Julien Duvivier. One of his most memorable roles was in director Jean Renoir's *Grande Illusion* (1937; *Grand Illusion*), a classic antiwar film. In *Quai des brumes* (1938; U.S. title, *Port of Shadows*) and *Le Jour se lève* (1939; *Daybreak*), both directed by Marcel Carné, Gabin was cast as a tough-willed son of misfortune surviving in a marginal world of social outcasts. In his later films, he often portrayed detective or gangland figures—e.g., Inspector Maigret and competent professional criminals in *Touchez pas au Grisbi* (1953), *Speaking of Murder* (1959), *Money, Money, Money* (1962), and *The Upper Hand* (1967).

**Gabinus, Aulus** (d. 47 bc, Salonae, Dalmatia [now Split, Croatia]), Roman politician and a supporter of Pompey the Great.

Gabinus, bronze bust, in the Museo Archeologico Nazionale, Naples  
Ainan—Art Resource

As tribune in 67 bc Gabinius proposed a law that gave Pompey command of the Mediterranean and all the land within 50 miles (81 km) of its coast as a means of controlling the depredations of pirates. Another Gabinian measure checked the lending of money to foreign ambassadors at Rome. Its object was to prevent the bribing of senators. As consul (58), Gabinius helped to procure the exile of Cicero.

As proconsul of Syria (57–54) he reinstated Hyrcanus as high priest at Jerusalem, suppressed revolts, introduced administrative changes in Judaea, and rebuilt several towns. He was sent by Pompey to Egypt, without the consent of the Senate, to restore Ptolemy XII Auletes to his kingdom. During his absence disturbances arose in Syria and Palestine, which he suppressed with some difficulty. He incurred the hostility of the *publicani* ("tax collectors"), and on his return to Rome he first had to face a charge of treason, on which he was acquitted; he was then condemned for extortion and sent into exile (54). Recalled

by Julius Caesar in 49, he fought for him in Illyricum (48–47) but died at Salonae (near modern Split).

**gable**, triangular section of wall at the end of a pitched roof, extending from the eaves to the peak. The gables in classical Greek temples are called pediments (*see* pediment).

The architectural treatment of a gable results from the effort to find an aesthetically pleasing solution to the problem of keeping water out of the intersection of walls and roof. This was accomplished either by carrying the roof out over the top of the end walls or by carrying the end walls up above the roof level and capping them with a waterproof coping. The former method is in general use in wooden and other small buildings with pitched roofs, while the latter method was used in larger and more monumental masonry structures, particularly those in the Gothic style.

The gable at the end of a ridge-roofed structure, or gable end, usually has straight sides, follows the roof's slope, and is often bounded by the roof's overhanging eaves. If the gable end projects above the roof level to form a parapet, however, its silhouette may be one of many types—such as the crow-stepped, catstepped, or corbiestepped gable—with a stepped outline. In this case, the edge of the parapet is often trimmed to form an ornamental silhouette. In northern and western Europe, where roofs of steep pitch are common, gables were often richly decorated with steplike or curved forms and were further ornamented with urns, statues, obelisks and scrolls. Among the earliest and most elaborate examples of buildings with parapet gables are the late medieval Dutch town houses of Amsterdam. Gables have also been important features in the traditional architecture of China and Japan. In these countries gables were ornamented with projecting roof tiles, grotesque sculptures of animals at the ridge and eaves, and occasionally with surface carving.

**Gable, Clark**, in full WILLIAM CLARK GABLE (b. Feb. 1, 1901, Cadiz, Ohio, U.S.—d. Nov. 16, 1960, Hollywood, Calif.), American film actor who for three decades was one of Hollywood's leading male stars. Gable rose to fame with his creation of a rough, masterful, romantic hero—a role epitomized in his portrayal of Rhett Butler in *Gone with the Wind* (1939).

The only son of an itinerant oil-field worker, Gable worked at a variety of odd jobs as a youth and then joined the Ed Lilly stock company as a callboy. Coached by his first wife, Josephine Dillon, a former actress, he played his first Broadway lead in *Machinal* (1928).

Gable had played bit parts in silent films as early as 1924. With the introduction of sound films, he returned to Hollywood in 1930 and was successful in a series of gangster roles that included *The Finger Points* (1931) and *Night Nurse* (1931). Under contract to Metro-Goldwyn-Mayer studios from 1931 to 1954, he switched gradually to the light-hearted, adventurous parts for which he became famous. During the 1930s, in such pictures as *Red Dust* (1932) and *Saratoga* (1937), two of several films made with actress Jean Harlow, and *Boom Town* (1940) and *San Francisco* (1936), in which he costarred with the prominent actor Spencer Tracy, Gable became the American ideal of virility. He won an Academy Award for his performance in *It Happened One Night* (1934) and was nominated for similar awards for his work in *Mutiny on the Bounty* (1935) and *Gone with the Wind*.

After the death in 1942 of his third wife, the actress Carole Lombard, Gable enlisted in the U.S. Army Air Corps during World War II; he won the Air Medal and achieved the rank of major. He appeared in several films in the late 1940s and '50s, notably in *Mogambo* (1953), a remake of *Red Dust*, and in *Run Silent, Run Deep* (1958). His final film role, completed

Gable in *Gone with the Wind*, 1939

© Metro Goldwyn-Mayer 1939

two weeks before his death, was as an aging cowboy in *The Misfits* (1961).

**Gabo, Naum**, original name NAUM NEEMIA PEVSNER (b. Aug. 5, 1890, Bryansk, Russia—d. Aug. 23, 1977, Waterbury, Conn., U.S.), pioneering Constructivist sculptor whose use of such materials as glass, plastic, and metal signaled a rejection of traditional concepts of mass in favour of a sense of spatial movement.

Gabo studied medicine, natural science, and engineering at the University of Munich. In 1913 he walked from Munich to Florence and Venice, absorbing art and architecture. Early in his life he changed his name to Gabo in order to distinguish himself from his brother, Antoine Pevsner, a painter. While in Paris in 1913/14 he met Alexander Archipenko and others involved with the avant-garde movement. In Stockholm in 1915 he produced his first Cubist-influenced sculptures, exemplified by "Head of a Woman" (1916, celluloid and metal). During World War I Gabo lived with his brother in Oslo, where they experimented along the Constructivist lines laid down by their fellow Russian Vladimir Tatlin.

Returning to Russia after the Revolution, Gabo and Pevsner saw political forces redirect art from exploration to propaganda. In 1920 they issued the "Realistic Manifesto" of Constructivism, which they posted and distributed in the streets of Moscow. In it they asserted

"Linear Construction in Space, Number 4," plastic and stainless steel sculpture by Naum Gabo, 1957–58; in the Whitney Museum of American Art, New York City

By courtesy of the Whitney Museum of American Art, New York City, gift of the Friends of the Whitney Museum of American Art

that art had a value and function independent of the state and that geometric principles should be the basis for sculpture. They advocated the use of transparent materials to define volumes of empty space instead of solid mass. In 1920 Gabo produced "Kinetic Composition," a motor-driven sculpture that demonstrated his principles by incorporating elements of space and time.

Gabo left Russia in 1922 and lived for 10 years in Berlin, where he worked with László Moholy-Nagy and other artists of the Bauhaus. During the 1920s Gabo continued to create monumental constructions out of glass, metal, and plastic. In 1932 he went to Paris, where he joined the Abstraction-Création group, an association of artists that advocated pure abstraction. He lived in England from 1936 to 1946, promoting Constructivism there by editing the collective manifesto *Circle* in 1937 with the abstract painter Ben Nicholson. Curves replaced angles in Gabo's new spatial constructions made of taut wire and plastic thread. He moved to the United States in 1946, and in 1953–54 he taught at the Harvard Graduate School of Architecture. During the 1950s Gabo received several commissions for public sculptures, only some of which he completed, such as the large commemorative monument for the Bijenkorf department store (1954, unveiled in 1957) in Rotterdam, Neth.

**Gabon**, officially GABONESE REPUBLIC, French GABON, or RÉPUBLIQUE GABONAISE, country of central Africa straddling the Equator on the west coast of Africa. It is bordered by Equatorial Guinea and Cameroon to the

Gabon

north, Congo (Brazzaville) to the south and east, and the Atlantic Ocean to the west (São Tomé and Príncipe lies off the coast). The capital is Libreville. Area 103,347 square miles (267,667 square km). Pop. (2003 est.) 1,329,000.

A brief treatment of Gabon follows. For full treatment, see *MACROPAEDIA*: Central Africa.

For current history and for statistics on society and economy, see *BRITANNICA BOOK OF THE YEAR*.

**The land.** Gabon and the basin of its major river, the Ogooué, are nearly coterminous; almost 90 percent of the basin lies within Gabon, comprising most of the eastern two-thirds of the country. Two lesser regions, the Woleu-Ntem River basin to the north and the coastal plain of the west and southwest (defined by an arc of highlands running roughly parallel to the coast), separate the upper Ogooué basin from the Atlantic Ocean. The lower Ogooué River collects water from a number of lakes on the coastal plain below Lambaréné before it empties into the Atlantic via a delta that separates the northern and southern stretches of the coastal plain.

Between the southern coastal plain and the upper Ogooué the Chaillu Massif rises to an elevation of 3,215 feet (980 m) at Mount Iboundji. The southern coastal plain is a continuation of the south of Congo's sand beaches, longshore bars, and coastal lagoons. The northern coastal plain, generally wider and with a more irregular coastline than its south-

ern counterpart, is separated from the upper Ogooué region by a series of plateaus ranging from 1,000 to 2,000 feet (300 to 600 m) above sea level. The plateaus merge northeastward to join the Cristal Mountains, establishing the divide between the Woleu-Ntem and Ogooué basins in the northwest.

Gabon has a typical equatorial climate. Rainfall is heavy and varies from an annual average of almost 120 inches (3,050 mm) at Libreville to 150 inches (3,810 mm) on the northwest coast, almost all of it falling between October and May. Despite the scarcity of rain from June to September, humidity remains high. Temperatures show little seasonal variation, daily averaging about 81° F (27° C).

About three-fourths of the country is covered by a dense equatorial rainforest containing more than 3,000 species of vegetation, including the okoume (Gabon mahogany), a hardwood that forms the backbone of Gabon's wood industry. The dense forest vegetation supports antelopes, monkeys, and a wide assortment of tropical birds, as well as gorillas and elephants.

Gabon's mineral resources are few but important. Its manganese reserves are among the largest in the world, and its interior has huge deposits of high-grade iron ore. Oil revenues provide about two-thirds of the national budget annually.

**The people.** Gabon has more than 40 distinct ethnic groups; almost all speak Bantu languages. (Most Gabonese use French, which is the country's official language, as a *lingua franca*.) The Fang, who belong to the larger Ewando or Pahouin group of central Africa, live north of the Ogooué River. The largest groups south of the river are the Punu, Sira, and Nzebi. Their less numerous neighbours are the Téké and Kota. About 90 percent of the population is Christian, with Roman Catholics by far more dominant than Protestant groups. Most of the rest are Muslims, and a small number practice traditional African religions.

Gabon, like most central African countries, has a low population density, and its population growth rate is one of the lowest in central Africa. More than two-fifths of the Gabonese are under age 15. With nearly half the population living in urban areas, Gabon is one of the most highly urbanized countries in sub-Saharan Africa.

**Economy.** Gabon has a mixed, developing economy based largely on the exploitation of mineral resources. The government has encouraged foreign investors with liberal economic policies, but there is also significant government direction and planning. The gross national product (GNP) is not growing as rapidly as the population; the per capita GNP, however, is the highest in tropical Africa.

Agriculture employs about two thirds of the workforce but plays a small role in the national economy. Farming is primarily subsistence, and production falls far short of domestic needs. The staple crops are plantains, sugarcane, and cassava.

Forestry was the primary industry in Gabon until mineral exploitation began in the early 1960s. Forest resources near the coast and rivers have been largely exhausted, and exploitation of the interior began with the construction of the Transgabon Railroad in the late 1970s.

The rapidly developing mining industry is the main source of Gabon's economic growth. Petroleum has become the most important mineral product, accounting for about one-third of the GNP and about three-fourths of total exports. The Gabonese government maintains a roughly one-third share in exploitation, which is carried out by foreign oil companies. Gabon also produces large amounts of manganese and some gold.

Manufacturing accounts for only a small per-

centage of the GNP, and a substantial amount of production is represented by timber (okoume) processing. Light industry has been expanding and diversifying since the opening in 1967 of a petroleum refinery at Port-Gentil. Annual production of electricity increased dramatically in the 1970s with the construction of the country's first hydroelectric plant at Kingulé, near Libreville. About two-thirds of Gabon's electricity is now generated by hydropower.

Exports, composed almost entirely of petroleum, forest products, and manganese, generally exceed imports. Principal trading partners include France and the United States. Gabon borrowed heavily from France, West Germany, and the European Economic Community (EEC) in the 1970s to build the Transgabon Railroad and initiate other development. At the insistence of creditors, the government is working toward a manageable external debt structure under an International Monetary Fund (IMF) stabilization plan.

**Government and social conditions.** Gabon is a unitary multiparty republic. The constitution, adopted in 1961 and subsequently revised, vests executive power in the president, who is elected by universal adult suffrage. The president appoints a cabinet. Legislative responsibility rests with a bicameral Parliament (Senate and National Assembly), whose members are elected by universal adult suffrage. Highest judicial authority lies in the Supreme Court. The High Court, composed of elected members of the National Assembly, has the power to try the president and other officials. From the late 1960s through the early 1990s, Gabonese politics was dominated by Omar Bongo; he remained president into the 21st century.

The country's social welfare system provides benefits to employed persons for work injury, maternity, disability, and old age. A family allowance law also offers benefits to employees with one or more children under the age of 16 years.

Like most of tropical Africa, Gabon is plagued by poor health conditions. Diseases borne by insects and vermin are widespread. Many Gabonese have cardiovascular and severe respiratory ailments, aggravated by the hot and humid climate. Provision of adequate health services and of maternal and child health programs is given top priority, perhaps in part because of the example set by the hospital that was maintained at Lambaréné by Albert Schweitzer. Nonetheless, Gabon's infant mortality rate is only slightly below average for countries in sub-Saharan Africa, and life expectancy is higher than that for the subcontinent at about 58 years. The country as a whole has a relatively high doctor-to-population ratio, but there remains a severe shortage of medical personnel in rural areas.

Education in Gabon is compulsory for children between the ages of 6 and 16, and about three-fourths of males and half of females are literate. The country's major institution of higher learning is Omar Bongo University (1971; founded as the National University of Gabon). Many students, however, go to France for a university education. All news media are owned and operated by the government.

Traditional Gabonese art is famous throughout Africa for its reliquary figures, ritual masks, and fetishes. A number of these objects are on display at the Gabon Museum of Arts and Traditions in Libreville. Although it has been independent since 1960, Gabon—formerly one of the four colonies of French Equatorial Africa—has retained close cultural ties with France; Gabonese intellectual and artistic life is often strongly influenced by French cultural developments.

**History.** Artifacts dating from late Paleolithic and early Neolithic times have been found in Gabon, but it is not known when the major migrations of Bantu speakers that established Gabon's ethnic composition occurred; it may have been as early as the beginning of the Christian era. Pygmies were probably the original inhabitants. The Fang, however, did not arrive before the late 18th century, when they were attracted to the Gabon coastal areas by the presence of European traders.

The Portuguese arrived at the Gabon Estuary in 1472 and were followed by French, Dutch, and English traders who operated along those coastal rivers that had trading networks reaching into the interior. The slave trade dominated commerce throughout the 18th and much of the 19th centuries. The French were the most successful in seeking treaties with the local population, and in 1839–41 they achieved the first transfer of sovereignty from the Mpongwe chieftains. From 1843 to 1886 Gabon was administered by French naval officers in conjunction with the French West Africa administration. In 1886 the colony of French Congo was established to include both Gabon and the Congo. In 1910 Gabon became a separate colony within the newly created French Equatorial Africa.

In 1898 Gabon was divided economically among concessionary companies, which became notorious for their exploitation of both human and natural resources. Despite continued protests, they were not fully dissolved until 1930.

In World War II Free French troops took over Gabon from the Vichy government in 1940, and in 1946 the colony became an overseas territory of France with its own territorial assembly. In 1958 it became an autonomous republic within the French Community. After concluding cooperation agreements with France, Gabon declared its independence on Aug. 17, 1960. Gabon's first president, Léon M'ba, was overthrown in 1964 but was restored to power with French military intervention. After M'ba's death in 1967, Gabon experienced stable growth and prosperity under his hand-picked successor, Omar Bongo. His long period of rule led to political restiveness by the early 1980s, but Gabon's continuing prosperity provided little incentive for drastic political action. From about 1986, however, petroleum prices began to decline, and popular discontent resulted from the economic downturn. Demonstrations in 1990 led to political liberalization and multiparty legislative elections later that year.

**Gabon Estuary**, French ESTUAIRE DU GABON, inlet of the Gulf of Guinea, in western Gabon. It is fed by the Como and Mbei rivers, which rise in the Cristal Mountains to the northeast. The estuary is 40 miles (64 km) long and 9 miles (14 km) wide at its mouth. It was explored in the 1470s by Portuguese navigators who may have named it Gabão ("Hooded Cloak with Sleeves"; hence *Gabon*) because of its shape, and it was long considered the finest harbour of the West African coast.

The main port on the estuary, Libreville, became Gabon's national capital and largest city. Logs are floated down the Como River to Owendo and Libreville on the estuary's northwest shore, and hydroelectric power is provided to the locality by a dam at Kinguélé upstream on the Mbei River.

**Gaboon viper** (*Bitis gabonica*), extremely venomous but usually docile snake of the family Viperidae, found in tropical forests of central Africa. It is the heaviest venomous snake in Africa and grows to a length of 2 m (about 7 feet) and a weight of 8 kg (18 pounds). The Gaboon viper is a thick-bodied,

Gaboon viper (*Bitis gabonica*)

Cy LaTour at the St. Louis Zoo

broad-headed snake with two hornlike projections on its snout. Its body is boldly patterned in rectangles and triangles of buff, purple, and brown.

**Gabor, Dennis** (b. June 5, 1900, Budapest, Hung.—d. Feb. 8, 1979, London, Eng.), Hungarian-born electrical engineer and winner of the Nobel Prize for Physics in 1971 for his invention of holography, a system of lensless, three-dimensional photography that has many applications.

A research engineer for the firm of Siemens and Halske in Berlin from 1927, Gabor fled Nazi Germany in 1933 and worked with the Thomson-Houston Company in England, later becoming a British subject. In 1947 he conceived the idea of holography and, by employing conventional filtered-light sources, developed the basic technique. Because conventional light sources generally provided either too little light or light that was too diffuse, holography did not become commercially feasible until the demonstration, in 1960, of the laser, which amplifies the intensity of light waves. In 1949 Gabor joined the faculty of the Imperial College of Science and Technology, London, where in 1958 he became professor of applied electron physics. His other work included research on high-speed oscilloscopes, communication theory, physical optics, and television. Gabor was awarded more than 100 patents.

**Gaboriau, Émile** (b. Nov. 9, 1832/33/35, Saujon, France—d. c. Oct. 1, 1873, Paris), French novelist who is best known as the father of the *roman policier* (detective novel). He has been described as the Edgar Allan Poe of France.

Gaboriau's prolific imagination and acute observation generated 21 novels (originally published in serial form) in 13 years. He made his reputation with the publication in 1866 of *L'Affaire Lerouge* (*The Widow Lerouge*) after having published several other books and miscellaneous writings. His later books, many of them classics of their kind, include *Le Crime d'Orcival* (1867; *The Mystery of Orcival*), *Monsieur Lecoq* (1868), *Les Esclaves de Paris* (1868; *The Slaves of Paris*), *La Vie infernale* (1870; *The Count's Millions*), and *L'Argent des autres* (1874; *Other People's Money*). Gaboriau created the fictional detectives Père Tabaret and Monsieur Lecoq; the latter was a fictional precursor of Sherlock Holmes.

**Gaborone**, formerly (until 1969) GABERONES, town, capital of Botswana. The seat of government was transferred there from Mafeking (now spelled Mafikeng), South Africa,

The National Assembly building in Gaborone, Botswana

D. Rawson—Photo Researchers

in 1965, one year before Botswana became independent of Britain. Gaborone is located on the Cape-Zimbabwe railway and is the site of government offices, parliament buildings, health facilities, a thermal power station, and an airport. It is the seat of the University of Botswana (founded 1976), and it also has a national museum and art gallery (1968), which includes departments of natural history, archaeology, and prehistory. Pop. (1997 est.) 183,487.

**Gabriel**, Hebrew GAVRI'EL, Arabic GIBRĀ'IL, JABRA'IL, or JIBRIL, in the Bible and the Qur'an, one of the archangels. Gabriel was the heavenly messenger sent to Daniel to explain the vision of the ram and the he-goat and to communicate the prediction of the Seventy Weeks. He was also employed to announce the birth of John the Baptist to Zechariah and to announce the birth of Jesus to the Virgin Mary. It is because he stood in the divine presence that both Jewish and Christian writers generally speak of him as an archangel. In the Books of Enoch "the four great archangels" are Michael, Uriel, Suriel (Raphael), and Gabriel, though elsewhere they are said to number seven. Gabriel's feast is kept on September 29. Both Gabriel's name and his functions were taken over by Islām from Judaeo-Christian tradition. His name is mentioned in the Qur'an only three times, but various epithets in that scripture are widely recognized as referring to him.

*A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume*

**Gabriel**, also called GABRIEL PROSSER (b. c. 1775, near Richmond, Va. [U.S.]—d. September 1800, Richmond), American bondsman who planned the first major slave rebellion in U.S. history (Aug. 30, 1800). His abortive revolt greatly increased the whites' fear of the slave population throughout the South.

The son of an African-born mother, Gabriel grew up as the slave of Thomas H. Prosser. Gabriel became a deeply religious man, strongly influenced by biblical example. In the spring and summer of 1800, he laid plans for a slave insurrection aimed at creating an independent black state in Virginia with himself as king. He planned a three-pronged attack on Richmond, Va., that would seize the arsenal, take the powder house, and kill all whites except Frenchmen, Methodists, and Quakers. Some historians believe that Gabriel's army of 1,000 slaves (estimates range from 2,000 to 50,000), assembled 6 miles (9.5 km) outside the city on the appointed night, might have succeeded had it not been for a violent rainstorm that washed out bridges and inundated roads. Before the rebel forces could be reassembled, Governor James Monroe was informed of the plot and ordered out the state militia. Gabriel and about 34 of his companions were subsequently arrested, tried, and hanged.

**Gabriel, Ange-Jacques**, also called JACQUES-ANGE GABRIEL (b. Oct. 23, 1698, Paris, France—d. 1782, Paris), French architect who built or enlarged many châteaux and palaces during the reign of Louis XV. He was one of the most important and productive French architects of the 18th century.

The most celebrated member of a family of architects, he was the son of Jacques V (1667–1742), whom he succeeded as premier architect to Louis XV and director of the Academy of Architecture in 1742. Gabriel was the chief architect for most of the major building projects undertaken during Louis XV's reign. Under him the royal châteaux and palaces were redesigned, enlarged, or renovated in order to satisfy Louis' standards of personal comfort. Among Gabriel's royal

commissions were enlargements or extensions of the châteaux of Fontainebleau (1749), La Muette (1746), Compiègne (1751), and Choisy (1752); additions to the Louvre (1755) in Paris; an ambitious project for the Palace of Versailles (1763), including the completion of its right wing and the building of the Opera House and the Petit Trianon there; and the construction of the École Militaire (1752) in Paris. Gabriel provided virtually all of the royal residences with theatres, also built pavilions and hermitages for some of them, and designed hunting lodges in the major royal forests. The magnificent Place Louis XV (now Place de la Concorde) in Paris (1755) demonstrates his talents as an urban planner.

Place de la Concorde, by Ange-Jacques Gabriel, Paris, 1755

A. Boisuerd/Shostal Associates

Gabriel was not a great innovator but rather was an extremely competent builder whose structures exhibit a "noble simplicity" in the austere but harmonious arrangement of their masses and their subdued classical decoration. He excelled at endowing large structures with majestic proportions, as exemplified in the École Militaire. He was also notable for his use of attached columns in place of pilasters, in both exterior and interior facades. His best-known work is the Petit Trianon at Versailles (1762), which is universally famous for its harmonious proportions and elegant, Palladian-inspired lines.

**Gabrieli, Andrea**, also called **ANDREA DI CANNAREGIO, CANNAREGGIO, or CANAREGGIO** (b. c. 1510–20, Venice—d. late 1586, Venice), Italian Renaissance composer and organist, known for his madrigals and his large-scale choral and instrumental music for public ceremonies. His finest work was composed for the acoustic resources of the Cathedral of St. Mark in Venice. He was the uncle of Giovanni Gabrieli.

He was born in the Canareggio quarter of Venice, but nothing is known about Andrea Gabrieli until 1536, when he became a singer at St. Mark's Cathedral and a pupil of its music director, the great Franco-Flemish composer Adriaan Willaert. From Willaert he learned the art of writing polyphonic motets and in particular that of composing for separated choirs placed in different parts of the church with consequent stereophonic effect. It is possible that Andrea was a singer at Verona cathedral around 1550.

In 1558 he became organist at the church of S. Geremia in Venice but soon left for an extended period of foreign travel. He served in the Bavarian court chapel at Munich under another great Franco-Fleming, Orlando di Lasso, then visited the court of Graz in Austria, and finally was patronized by the noble Fugger family in Augsburg. In 1564 he returned to Venice to become second organist at St. Mark's, where he remained until 1584, when he succeeded the virtuoso performer Claudio Merulo as first organist—a position he held until his death in 1586. Despite his profession, not much of his output in these years was organ music; there were several volumes of madrigals, socially enjoyable settings of Italian poetry to be sung at private

houses or cultural academies, where musical life flourished. And there was the large-scale choral and instrumental music for ceremonies of church and state, for which Andrea is best-known today. His motets and masses exploit the tonal variety possible when instruments are added to a choir. Some of these works were published posthumously in 1587: one of the finest is the *Magnificat* for three choirs and orchestra, doubtless intended to be performed in St. Mark's.

**MAJOR WORKS.** Madrigals for three to six voices in various collections; masses in six parts, *Primus liber missarum* (1572); *Magnificat* for three choirs; motets; various ricercari and canzoni.

**Gabrieli, Giovanni** (b. 1556?, Venice—d. Aug. 12?, 1612, Venice), Italian Renaissance composer, organist, and teacher, celebrated for his sacred music, including massive choral and instrumental motets for the liturgy.

Giovanni Gabrieli studied with his uncle, Andrea Gabrieli, whom he regarded with almost filial affection. To the latter's foreign travels and connections Giovanni owed his chance to become known abroad. Giovanni also served (1575–79) under Orlando di Lasso in Munich. In 1584 he returned to Venice and a year later succeeded his uncle as second organist of St. Mark's Cathedral—the post he held for life.

After Andrea's death in 1586, Giovanni quickly assumed the limelight in the field of ceremonial music, though he was never so active as a madrigalist. The publication of his uncle's music in 1587 was a mark of respect but also included some of his own church music. Giovanni's foreign connections included Hans Leo Hassler, the German composer and former pupil of Andrea, who avidly adopted the Venetian style, and patrons, such as the Fugger family and Archduke Ferdinand of Austria. In later years Giovanni became a famous teacher; his most notable student was the German Heinrich Schütz.

After 1587 Giovanni's principal publications were the two immense *Sacrae symphoniae* of 1597 and 1615 (printed posthumously), both of which contained purely instrumental music for church use or massive choral and instrumental motets for the liturgy. Like his uncle, he usually conceived the music for separated choirs but showed an increasing tendency to specify which instruments were to be used and which choirs were to consist of soloists and full choir, as well as to distinguish the musical style of each, thus initiating a completely new approach to the creation of musical colour and orchestration. In the well-known *Sonata pian e forte*, for eight instruments, directions to play loud and soft are given. Among the motets, his masterpiece is perhaps *In ecclesiis*, for four soloists, four-part choir, violin, three cornets, two trombones, and organ, these forces pitted against one another in an endless variety of combinations.

**MAJOR WORKS.** Various motets, among them *In ecclesiis*; madrigals in various collections; *Canzoni e sonate* (1615); *Sacrae symphoniae*, book 1 (1597), including the *Sonata pian e forte*; *Sacrae symphoniae* (1615); *Concerti di Andrea et di Giovanni Gabrieli a 6–16 voci* (1587, containing pieces by Andrea).

**BIBLIOGRAPHY.** Egon Kenton, *Life and Works of Giovanni Gabrieli* (1967); and Denis Arnold, *Giovanni Gabrieli and the Music of the Venetian High Renaissance* (1979, reprinted 1986).

**Gabrielino**, also called **SAN GABRIELINO, or GABRIELEÑO**, any of two—and possibly three—dialectally and culturally related North American Indian groups who spoke a language of Uto-Aztecan stock and lived in the lowlands, along the seacoast, and on islands in southern California. The Gabrielino proper inhabited what are now southern and eastern Los Angeles County and northern Orange County, as well as the islands of Santa Catalina and San Clemente; they were named after the

Franciscan mission San Gabriel Arcángel (and thus have sometimes been called San Gabrielinos). The second group, Fernandino (Fernandino, or San Fernandinos, named after the mission San Fernando Rey de España), occupied areas in and around the San Fernando Valley and some seacoast. A third apparently related group were the Nicolino (Nicolino, or San Nicolinos), who inhabited San Nicolas Island. The Gabrielino groups occupied some of the most fertile and pleasant land in California, and, because they were among the wealthiest and most advanced Indians in the region, they exercised considerable influence on all their neighbours. In religion, for instance, the Gabrielino were the source of the jimsonweed cult, a widely practiced southern California religion that involved various sacred and esoteric rituals and the drinking of toloache, a hallucinogen made from the jimsonweed (*Datura stramonium*).

The interior and coastal Gabrielino lived in houses constructed of poles and tule mats and relied on gathering acorns and other plant foods, supplemented by fishing and hunting. Island Gabrielino, especially the Nicolino, often built dwellings of whale ribs covered with sea-lion skins or brush; and for food they relied more on fish, sea mammals and birds, and mollusks. All groups made baskets; and from Santa Catalina Island came soapstone that was made into such items as pots and scoops, ceremonial vessels, artistic carvings, beads, and ornaments. Trade between islanders, coastal people, and interior Indians was extensive, using currency of clamshell beads. Each Gabrielino village had a hereditary chief and shamans.

No identifiable Gabrielino now exist. See also Mission Indians.

**Gabrilowitsch, Ossip (Salomonovich)** (b. Feb. 7, 1878, St. Petersburg—d. Sept. 14, 1936, Detroit), Russian-born American pianist noted for the elegance and subtlety of his playing.

After study with two of the outstanding pianists of his day—Anton Rubinstein in St. Petersburg and Theodor Leschetizky in Vienna—Gabrilowitsch toured widely in Europe and the United States. In 1909 he married Mark Twain's daughter, the singer Clara Clemens, with whom he frequently gave recitals. After having conducted in Munich and Vienna he became (1918) conductor of the Detroit Symphony Orchestra.

**Gabrovo**, town, north-central Bulgaria. It is situated on both banks of the Yantra River, at the foot of the Shipka Pass in the Balkan Mountains. A major industrial centre, Gabrovo has a high in-migration population from the surrounding area. Called the "Bulgarian Manchester," the town has a large textile industry—clothes, leather goods, and accessories. Other manufactures are machine tools, footwear, electrical machinery, and textile machinery.

According to legend, the town was founded in the mid-15th century by an itinerant blacksmith, who was later joined by other craftsmen. In 1835 the first Bulgarian secular school opened there, and in 1877 the town was liberated from the Turks. In the mountains to the south, craft industries are maintained in textiles, woodworking, and carpet making. Pop. (1989 est.) 80,930.

**Gabú**, formerly **NOVA LAMEGO**, town, eastern Guinea-Bissau, western Africa. Gabú is situated along the Colufe River, a tributary of the Gêba River, and is an agricultural marketing centre. Peanuts (groundnuts), grown mainly by the Muslim Fulani peoples, are the principal crop of the region. The town is connected by road to Bissau, the national

capital, and to other coastal towns. Pop. (1997 est.) town, 10,000.

**gaccha**, among the image-worshipping Śvet-āmbara sect of the Indian religion of Jainism, a group of monks and their lay followers who claim descent from eminent monastic teachers. Although some 84 separate *gacchas* have appeared since the 7th–8th century, only a few have survived, such as the Kharatara (located mainly in Rājasthān), the Tapā, and the Añcala. While the *gacchas* do not differ from one another in matters of doctrine, they do differ on issues of practice, in particular those practices relating to the sacred calendar and to ritual. The various *gacchas* also trace their descent through different lineages.

**Gad**, one of the 12 tribes of Israel that in biblical times composed the people of Israel who later became the Jewish people. The tribe was named after the elder of two sons born to Jacob and Zilpah, a maidservant of Jacob's first wife, Leah.

After entering the Promised Land, each tribe was assigned a territory by Joshua, who replaced Moses as leader after the latter's death. The tribe of Gad settled on land east of the Jordan River, gained renown for its military spirit, and was one of the 10 northern tribes that formed a separate kingdom in 930 BC with Jeroboam I as king. Following the Assyrian conquest of 721 BC, the 10 tribes were partially dispersed and eventually assimilated by other peoples. The tribe of Gad thus became one of the Ten Lost Tribes of Israel.

**Gadamer, Hans-Georg** (b. Feb. 11, 1900, Marburg, Ger.—d. March 13, 2002, Heidelberg), German philosopher whose system of philosophical hermeneutics, derived in part from concepts of Wilhelm Dilthey, Edmund Husserl, and Martin Heidegger, was influential in 20th-century philosophy, aesthetics, theology, and criticism.

The son of a chemistry professor, Gadamer studied the humanities at the universities of Breslau, Marburg, Freiburg, and Munich, earning his doctorate in philosophy under Heidegger at Freiburg in 1922. He lectured in aesthetics and ethics at Marburg in 1933, at Kiel in 1934–35, and again at Marburg, where he was named extraordinary professor in 1937. In 1939 he was made full professor at the University of Leipzig. He later taught at the universities of Frankfurt am Main (1947–49) and Heidelberg (from 1949). He became professor emeritus in 1968.

Gadamer's most important work, *Wahrheit und Methode* (1960; *Truth and Method*), is considered by some to be the major 20th-century philosophical statement on hermeneutical theory. His other works include *Kleine Schriften* (1967–77; *Philosophical Hermeneutics*, selected essays from vol. 1–3); *Dialogue and Dialectic* (1980), comprising eight essays on Plato; and *Reason in the Age of Science* (1982), a translation of essays drawn from several German editions.

**Gadames** (Libya): see Ghadāmis.

**Gadara**, modern UMM QAYS, ancient city of Palestine, a member of the Decapolis, located just southeast of the Sea of Galilee in Jordan. Gadara first appeared in history when it fell to the Seleucid Antiochus the Great (218 BC); the Jewish king Alexander Jannaeus took it after 10 months' siege (c. 100 BC). It was restored by the Roman general Pompey, and Augustus gave it to Herod the Great (30 BC). Archaeological remains include three large theatres, a basilica, a temple, and a colonnaded street.

**Gadda, Carlo Emilio** (b. Nov. 14, 1893, Milan, Italy—d. May 21, 1973, Rome), Italian essayist, short-story writer, and novelist outstanding particularly for his original and inno-

vative style, which has been compared to that of James Joyce.

Gadda was educated as an electrical engineer, and during the 1920s he worked as an engineer abroad. He began writing in the 1930s and from the first demonstrated a fascination and facility for language as well as a gift for unemotional and acute psychological and sociological analysis. His first works were collected in *I sogni e la folgore* (1955; "The Dreams and the Lightning"). Gadda's best-known and most successful novel, *Quer pasticciaccio brutto de via Merulana* (1957; *That Awful Mess on Via Merulana*), is a story of a murder and burglary in fascist Rome and of the subsequent investigation, which features characters from many levels of Roman life. The language of the novel, known to Italians as *Il pasticciaccio* ("The Pastiche"), is literary Italian, with an admixture of three Roman dialects and puns, technical jargon, foreign words, parodies, made words, and classical allusions. Gadda's approach is as mercurial as his style: ironic, bitter, outrageously comic, philosophical, and obscene.

Gadda's *La cognizione del dolore* (1963, revised 1970; *Acquainted with Grief*) is autobiographical, though its setting is transferred from modern Italy to an invented South American country.

**Gaddi, Agnolo** (b. c. 1350, Florence [Italy]—d. Oct. 16, 1396, Florence), son and pupil of Taddeo Gaddi, who was himself the major pupil of the Florentine master Giotto. Agnolo was an influential and prolific artist who was the last major Florentine painter stylistically descended from Giotto.

In 1369 he was employed in Rome as an assistant to his brother Giovanni, a minor painter, in the execution of frescoes for Pope Urban V in the Vatican. In the 1380s he executed his most ambitious works, a series of frescoes in the choir of Santa Croce in Florence illustrating the "Legend of the True Cross." In these frescoes Agnolo sacrificed expression for design, and his overall concern with optical unification of the composition replaces Giotto's concentration on figures, thereby revealing the new approach toward painting of the International Gothic style. Between 1383 and 1386 Agnolo designed medallions representing the virtues for the Loggia dei Lanzi in Florence, and between 1387 and 1395 his name appears

"Resurrection of Drusiana," scene from the fresco "Legend of the True Cross," by Agnolo Gaddi, c. 1380; in the Church of Santa Croce, Florence

SCALA—Art Resource/EB Inc.

as the designer or gilder of statues for the facade of the Cathedral of Florence. In 1394–96 he painted a cycle of scenes from the life of the Virgin in the Cathedral of Prato. His death in 1396 left unfinished an altar of the Crucifixion in San Miniato al Monte outside Florence.

**Gaddi, Taddeo** (b. c. 1300, Florence [Italy]—d. 1366?, Florence), pupil and most faithful follower of the Florentine master Giotto. A

capable artist, although lacking his teacher's comprehensive aesthetic vision, he was, after Giotto's death, the leading Florentine painter for three decades.

His earliest authenticated work is a small triptych with the Virgin enthroned with Child and saints, signed and dated 1334. In 1332, however, and possibly as early as 1328, he had already begun to work with Giotto on the fresco decoration of Santa Croce in Florence. The earliest of Gaddi's works in the Baroncelli Chapel of Santa Croce were scenes from the life of the Virgin and the life of Christ, completed in 1338. Less concerned with drama and with monumental compositional clarity than his master, Gaddi gave in these works more attention to picturesque, narrative detail. Although he copied Giotto's heavy, naturally treated figures and bare landscapes and the general sober and impressive tenor of his works, in introducing more complicating elements he went beyond the bounds that Giotto had carefully set for his own art—those of simplicity and unindividualized figures that free his scenes from the particular and allow them a dramatic and universal impact. Gaddi's frescoes are thus less powerful, if more lively, than those of his master, although his innovative spirit led him to experiments with the representation of light that are highly effective, as in his mysteriously radiant "Annunciation to the Shepherds."

Possibly in about 1338 Gaddi decorated the sacristy of Santa Croce with panels representing the lives of Christ and of St. Francis. In 1341–42 he appears to have been employed in San Miniato al Monte outside Florence and in San Francesco at Pisa. At some point in the 1340s Gaddi decorated the walls of the refectory at Santa Croce, painting there one of the most impressive of his works, a "Tree of Life" surrounded by scenes from the life of St. Bonaventure, a work of much vigour, with a rich iconography. The scenes of this work, like those of the other refectory frescoes, are composed with a classical simplicity that represents a retreat from Gaddi's earlier stylistic rebellion. Following Giotto's death in 1337, Gaddi became the leader of Giotto's school in Florence. Between 1347 and 1353 he painted a polyptych for San Giovanni Fuorcivitas at Pistoia, and in 1355 he executed a signed and dated "Madonna in Glory" for San Lucchese at Poggibonsi. In 1366 he is mentioned in documents for the final time.

**Gaddis, William (Thomas)** (b. Dec. 29, 1922, New York, N.Y., U.S.—d. Dec. 16, 1998, East Hampton), American novelist of complex, satiric works who was considered one of the best of the post-World War II modernist writers.

After incomplete studies at Harvard University (1941–45), Gaddis worked as a fact checker for *The New Yorker* magazine for two years and then traveled widely in Central America and Europe, holding a variety of jobs. He first gained note as an author with publication of his controversial novel *The Recognitions* (1955). This book, rich in language and imagery, began as a parody of Faust but developed into an examination of spiritual bankruptcy that has been called both a brilliant masterpiece and incomprehensibly excessive. It became an underground classic, but, discouraged by the harsh critical reception of his book, Gaddis worked as a freelance writer for various corporations and published nothing for 20 years. His second novel, *JR* (1975), uses long stretches of cacophonous dialogue to depict what its author viewed as the greed, hypocrisy, and banality of the world of American business. Gaddis' third novel, *Carpenter's Gothic* (1985), is even more pessimistic in its depiction of moral chaos in modern America. The law, lawyers, and especially the litigiousness rampant in contemporary American society are examined in *A Frolic of His Own* (1994).

Gaddis' fiction shows the influence of the

writings of James Joyce and, in turn, influenced the work of Thomas Pynchon; it contains long dialogues and monologues related by a minimum of plot and structured by scant punctuation. His books belong to a style of literature characterized by the absence of distinctive incidents and the pervasive use of black humour in dealing with a chaotic mass of associations. They create a radical way of viewing the world by which the reader can reassess his own situation.

**Gade, Niels (Vilhelm)** (b. Feb. 22, 1817, Copenhagen—d. Dec. 21, 1890, Copenhagen), Danish composer who founded the Romantic nationalist school in Danish music. He studied violin and composition and became acquainted with Danish poetry and folk music. Both Mendelssohn and Schumann, who were

Gade, detail of a lithograph by Josef Kriehuber

By courtesy of the Österreichische Nationalbibliothek Vienna

his friends, were attracted by the Scandinavian character of his music. Schumann wrote of him in the *Neue Zeitschrift für Musik*, and in 1843 Mendelssohn conducted Gade's first symphony in Leipzig. Gade conducted in Leipzig from 1844 to 1848 and became conductor of the Copenhagen Musical Society in 1850. In 1866 he became a director of the new Copenhagen Conservatory. Gade's early works, reflecting the spirit of Danish folk tunes, were among the first 19th-century examples of the use of native musical idioms and nationalist themes. Under the influence of Mendelssohn, his later works show greater technical command, often at the expense of the style that had made his earlier works attractive. His compositions include the overtures *Echoes from Ossian* (published as Opus 1) and *In the Highlands*; the cantatas *Zion*, *The Crusaders*, and *Psyche*; eight symphonies; three ballets; a violin concerto; a string quartet; and other works.

**gadfly petrel**, any of several species of petrels distinguished from others by their fluttering type of flight. *See* petrel.

**Gadifer de la Salle** (fl. c. 1340–1415), French soldier who, with Jean de Béthencourt, conquered and explored the Canary Islands.

Gadifer won renown in the French campaigns against England during the Hundred Years' War (1337–1453). While on a crusade against Tunis in 1390, he met Béthencourt, who later pledged his lands to finance their expedition to the Canary Islands. In 1402 they occupied Lanzarote, the northernmost inhabited island of the Canaries. Gadifer then explored the archipelago, and Béthencourt left for Cádiz, where he procured reinforcements at the Castilian court. In 1404 Béthencourt returned to the Canaries as king (a title granted by Henry III of Castile in exchange for Béthencourt's homage); Gadifer, slighted, returned to France.

**Gadjah Mada** (Indonesian leader): *see* Gajah Mada.

**gadolinium** (Gd), chemical element, rare-earth metal of transition Group IIIB of the

periodic table. Silvery white and moderately ductile, the metal reacts slowly with oxygen and water. Below 17° C it is ferromagnetic and at very low temperatures, superconducting. Credit for the discovery of gadolinium is shared by J.-C.-G. de Marignac and P.-É. Lecoq de Boisbaudran. Marignac separated (1880) a new rare earth (metallic oxide) from the mineral samarskite; Lecoq de Boisbaudran obtained (1886) a fairly pure sample of the same earth, which with Marignac's assent he named gadolinia, after a mineral in which it occurs that in turn had been named for the Finnish chemist Johan Gadolin. Gadolinium occurs in many minerals along with the other rare earths but is obtained primarily from monazite. It is found also in the products of nuclear fission. Commercial separation depends upon ion-exchange techniques. The metal has been produced by thermoreduction of the anhydrous chloride or fluoride by calcium.

Gadolinium is used for certain electronic components and high-temperature refractories and as an alloying agent. H. Kamerlingh Onnes first produced (1923) temperatures below 1 K by magnetic cooling using gadolinium sulfate. Gadolinium has the highest absorption cross section for thermal neutrons of any natural isotope of any element (49,000 barns), which suggests its use in nuclear reactor control rods. The seven natural stable isotopes have mass numbers between 152 and 160; the species of highest mass numbers are more abundant.

Gadolinium is trivalent in all of its compounds; it behaves as a typical rare earth. Its salts are white, and its solutions are colourless.

atomic number	64

**gadrooning** (architecture): *see* fluting and reeding.

**Gadsden**, city, seat (1866) of Etowah county (then Baines county), northeastern Alabama, U.S., on the Coosa River (there dammed to form an 8,000-ac [3200-ha] lake), in the Appalachian foothills. The original farming settlement, founded in 1846 as Double Springs, was renamed for James Gadsden, who negotiated the Gadsden Purchase (1853) of territory from Mexico. Adjacent Alabama City was annexed by Gadsden in 1932. A diversified economy developed with hydropower and the exploitation of local resources (iron, coal, manganese, limestone, and timber). Gadsden is the seat of an extension division of the University of Alabama, the Alabama Technical College, and Gadsden State Junior College. Noccalula Falls in a city park drops 95 ft (29 m) over a ridge of Lookout Mountain into a valley pool. Inc. city, 1871. Pop. (1990) city, 42,523; Gadsden MSA, 99,840.

**Gadsden, James** (b. May 15, 1788, Charleston, S.C., U.S.—d. Dec. 26, 1858, Charleston), U.S. soldier, diplomat, and railroad president, whose name is associated with the Gadsden Purchase (*q.v.*).

He graduated from Yale College in 1806 and engaged in business in his native city until 1812, when he was appointed a lieutenant of engineers in the U.S. Army. In 1820 he was made responsible for the establishment of military posts in Florida and supervised the removal of the Seminole Indians to southern Florida in 1823. Gadsden negotiated the treaty for the removal of the Seminoles to the west in 1832 and served in the war that followed the refusal of some Seminoles to leave Florida. In 1840 he became president of a railroad in South Carolina.

Gadsden's most important public service followed his appointment as U.S. minister to

Mexico in 1853. He was instructed to negotiate a treaty for the purchase of territory south of the Gila River through which ran the most desirable route for a railroad from the southern states to the Pacific. He succeeded in adjusting certain minor issues and in gaining a cession of territory in what is now southern New Mexico and Arizona. This added territory, which included the route of the proposed southern railroad, is generally known as the Gadsden Purchase.

**Gadsden Purchase** (signed Dec. 30, 1853, Mexico City; revised treaty ratified April 25, 1854), transaction that followed the conquest of much of northern Mexico by the United States in 1848. It assigned to the United States nearly 30,000 additional square miles (78,000 square kilometres) of northern Mexican territory, now southern Arizona and southern New Mexico. Prompted by advocates of a southern transcontinental railroad for which the most practical route would pass through the acquired territory, and by demands for U.S. protection of private concessions in the area, the purchase was negotiated by the U.S. minister to Mexico, James Gadsden, for \$10,000,000.

**Gadus**, fish genus of the family Gadidae, including the individuals and groups known as bib, cod, pollock, and whiting (*qq.v.*).

**gadwall** (*Anas strepera*), small, drably coloured duck of the family Anatidae, a popular game bird. Almost circumpolar in distribution in the Northern Hemisphere, the gadwall breeds above latitude 40° and winters between 20–40°. In North America the densest breeding populations occur in the Dakotas and the prairie provinces of Canada; the coast of Louisiana is a primary wintering area. These brownish gray birds have white patches, visible only during flight, on the rear of the wings. Breeding males are gray with a brown head and neck and black posteriors. Their preferred diet consists of stems and leaves of aquatic plants, supplemented by seeds and algae. Gadwalls frequent shallow freshwater ponds and marshes, often in mixed flocks with wigeons. Unlike wigeons, however, they rarely feed on land. The nest is hidden in thicker vegetation than is usual for species of the dabbling duck (*q.v.*) group.

**Gaea**, also called GE, Greek personification of the Earth as a goddess. Mother and wife of Uranus (Heaven), from whom the Titan

Gaea, terra-cotta statuette from Tanagra; in the Musée Borély, Marseille

Graudon—Art Resource/EB Inc

Cronus, her last born child by him, separated her, she was also mother of the other Titans, the Gigantes, the Erinyes, and the Cyclopes (see giant; Fury; Cyclops); hence literature and art sometimes made her the enemy of Zeus, for the Titans and Gigantes threatened him. Gaea may have been originally a mother goddess worshipped in Greece before the Hellenes introduced the cult of Zeus. Less widely worshipped in historic times, Gaea was described as the giver of dreams and the nourisher of plants and young children.

**Gaekwar** DYNASTY, also spelled GAIKWAR, or GAEKWAD, Indian ruling family and title of its head whose capital was at Baroda in Gujarāt state. The state became a leading power in the 18th-century Marāthā confederacy.

The founder of the dynasty was Damaji I who had risen to power by 1740. The last Gaekwar, Sayaji Rao III, died in 1939.

**Gaelic football**, Irish version of football, an offshoot of Britain's medieval *mêlée*, in which entire parishes would compete in daylong matches covering miles of countryside. A code of rules slightly restricting the ferocity of the sport was adopted in 1884, and the Gaelic Athletic Association was formed the same year to govern competition.

Gaelic football match between Cavan and Derry, Breehni Park, Cavan, Ire., 2000

Lohan—SPORTSFILE

In the modern game, sides are limited to 15 each. Players may not throw the ball, but they may dribble with hand or foot, punch, or punt the ball toward their opponent's goal. One point is scored for putting the ball between the goalposts and over the crossbar and three points for putting it between the posts and under the bar into a net. A game is divided into two 30-minute periods. Gaelic football is not played much outside Ireland and the United States; the winners of the annual all-Ireland championship usually visit the United States to play its teams.

**Gaelic language:** see Irish language; Scottish Gaelic language.

**Gaelic League:** see Irish literary renaissance.

**Gaelic revival**, resurgence of interest in Irish language, literature, history, and folklore inspired by the growing Irish nationalism of the early 19th century. By that time Gaelic had died out as a spoken tongue except in isolated rural areas; English had become the official and literary language of Ireland. The discovery by philologists of how to read Old Irish (written prior to 900) and the subsequent translations of ancient Gaelic manuscripts (e.g., *The Annals of the Four Masters*) made possible the reading of Ireland's ancient literature. Heroic tales caught the imagination of the educated classes. Anglo-Irish poets experimented with verse that was structured according to Gaelic patterns and rhythms and that echoed the passion and rich imagery of ancient bardic verse.

In 1842 the patriotic organization known as Young Ireland founded *The Nation*, a paper that published the works of Thomas Osborne Davis, a master of prose and verse, and of such poets as Thomas D'Arcy McGee, Richard D'Alton Williams, and Speranza (the pseudonym of Lady Wilde, mother of Oscar Wilde). *The Dublin University Magazine* (1833–80), another important literary publication, often included the work of James Clarence Mangan, who translated Gaelic poems into English and also wrote original verse in the Gaelic style. Jeremiah John Callanan was the first to use the Gaelic refrain in English verse, and Sir Samuel Ferguson wrote epic-like poetry recalling Ireland's heroic past. Thomas Moore, Charles Maturin, and Maria Edgeworth also incorporated Irish themes from earlier Gaelic works into their writings.

The Gaelic revival was not a widespread, vigorous movement because political nationalism and the need for land reform overshadowed cultural nationalism. The revival did, however, lay the scholarly and nationalistic groundwork for the Irish literary renaissance (q.v.), the great flowering of Irish literary talent at the end of the 19th and beginning of the 20th century.

**Gaeta**, Latin CAIETA, town, seaport, and archiepiscopal see, Latina province, Lazio (Latium) region, south central Italy, on the Golfo di Gaeta, northwest of Naples (Napoli). Gaeta first came under the influence of the Romans in the 4th century BC; a road was built c. 184 BC connecting the town with the port, and it became a favoured Roman resort. After the fall of the Roman Empire in the 5th century AD, Gaeta remained loyal to the Byzantine Empire and preserved its independence throughout Gothic, Lombard, and Saracen wars and invasions. A maritime republic in the 8th century and autonomous duchy after 915, it capitulated in 1140 to the Normans, under whom it achieved great importance. In the 15th century it was the centre of struggles for succession to the throne of Naples. Its capitulation to the Kingdom of Italy in 1861 marked the end of the Bourbon Kingdom of the Two Sicilies.

Outside the old walls the town has a modern appearance, but within them the character of a fortified square is preserved. The old town is dominated by the cathedral (1106–1278), which was restored in 1792 and contains a museum; and the Castello, the lower part of which dates from c. 1289 and the upper from c. 1435. The Monte d'Orlando (a public park) is supposed to be the site of the grave of Caieta (the nurse of Aeneas, mythical hero of Troy and Rome), after whom the town was named.

Gaeta is a fishing port and seaside resort. It has a petroleum refinery and a glassworks. Pop. (2001 est.) 22,515.

**Gaetani** FAMILY: see Caetani family.

**Gaetano** (theologian): see Cajetan.

**Gaetano** DA THIENE (Catholic reformer): see Cajetan of Thiene, Saint.

**Gaète, Martin-Michel-Charles Gaudin, duc de** (duke of): see Gaudin, Martin-Michel-Charles.

**Gaetulia**, ancient district of interior North Africa that in Roman times, at least, was inhabited by wandering tribes, the Gaetuli. The area, not clearly defined, included the southern slopes of the Atlas Mountains, from the Aurès Massif westward as far as the Atlantic; southward it extended to the oases in the northern part of the Sahara. Distinguished from the Negro tribes to the south, the Gaetuli belonged to the Berber peoples who formed the population of Numidia. The tribes were noted for their horse breeding; they dressed in skins and lived on flesh and milk. The only manufacture connected with their name was

that of purple dye. The modern nomadic tribes of the area are probably of the same lineage.

**Gafencu, Grigore** (b. Jan. 30, 1892, Bucharest—d. Jan. 30, 1957, Paris), Romanian diplomat, journalist, and politician who as foreign minister at the outbreak of World War II tried to maintain Romania's neutrality.

Gafencu, 1939

Keystone

Educated at Geneva and Paris, Gafencu entered journalism after World War I. In 1924 he became editor and publisher of *Argus*, a leading economic periodical, and during the 1930s founded *Timpul*, which soon became Bucharest's leading daily journal. He also established the Orient-Radio news agency. As a member of the National Peasant Party, he was elected to the Romanian Parliament in 1928 and served in various cabinet-level posts. Appointed foreign minister in December 1938 as a gesture to the Western democracies, he tried to balance Romania's East-West relations but was eventually dismissed to appease the Axis powers (June 2, 1940). During 1940–41 he served as minister to the Soviet Union, but soon after his return to Romania in June 1941 he left for Switzerland. After World War II he settled in Paris. In November 1947, after a communist government had seized power in Romania, he was sentenced in absentia to 20 years' imprisonment. He wrote *Préliminaires de la guerre à l'Est* (1944; *Prelude to the Russian Campaign*, 1945) and *Derniers jours de l'Europe* (1946; *Last Days of Europe*, 1948).

**Gaffney**, city, seat of Cherokee county, northern South Carolina, U.S., near the Broad River. Named for Michael Gaffney, an Irish settler who arrived in 1803, it early developed as a resort where plantation owners sought therapeutic treatment at local limestone springs. Its growth as a market centre for cotton and farm produce was sustained by the coming of the Southern Railway in the 1870s. Limestone College was founded there in 1845. Industrial activities include textile milling, metal working, and food processing. The Revolutionary battlefields of Kings Mountain (commemorated by a military park) and Cowpens are nearby. Inc. 1875. Pop. (2000) 12,968.

**Gafsa** (Tunisia): see Qafṣah.

**gag rule**, in U.S. history, any of a series of congressional resolutions that tabled, without discussion, petitions regarding slavery; passed by the House of Representatives between 1836 and 1840 and repealed in 1844. Abolition petitions, signed by more than 2,000,000 persons, had inundated Congress after the establishment of the American Anti-Slavery Society (1833). Gag rules, supported by proslavery congressmen, postponed the consideration, printing, and referral of such petitions. Repeal was secured by a House group led by the former president John Quincy Adams and Joshua R. Giddings.

**gagaku** (Japanese), Korean A-AK, ancient court music. The name is a Japanese pronunciation of the Chinese characters for elegant

music (*ya yueh*). Such music first appeared in Japan as an import from Korea in the 5th century and had become an established court tradition by the 8th century. The various forms of North Asian, Chinese, Indian, Southeast Asian, and indigenous Japanese music were organized in the 9th century into two major categories: *tōgaku*, the so-called music of the left, included Chinese and Indian materials; and *komagaku*, the music of the right, contained the rest. The flute and main drum of the two ensembles differ, and *komagaku* does not use strings. Purely instrumental performances of *gagaku* are called *kangen* (flutes and strings), while dances and their accompaniment are called *bugaku*. Various forms of Shintō ritual or ancient vocal music also survive.

The solo music for the instruments of *gagaku* has been lost, although some notations survive. The mnemonic nature of the notation and the rote methods of teaching the music make it difficult to reconstruct such lost traditions as well as to evaluate the present performance practice of existing ensemble music. Nevertheless, the very continuance of such ancient forms through all the vicissitudes of history gives extremely rare living insights into the probable nature of music and cultural life in East Asia 1,000 years ago. *Gagaku* and Korean *a-ak* not only provide information about traditional national musical forms but also are the major sources for clues concerning the music of China's brilliant T'ang dynasty period (618–907).

**Gagarin, Yuri Alekseyevich** (b. March 9, 1934, near Gzhatsk, Russian S.F.S.R.—d. March 27, 1968, near Moscow), Soviet cosmonaut who in 1961 became the first man to travel into space.

The son of a carpenter on a collective farm, Gagarin graduated as a molder from a trade school near Moscow in 1951. He continued his studies at the industrial college at Saratov and concurrently took a course in flying. On completing this course he entered the Soviet Air Force cadet school at Orenburg, from which he graduated in 1957.

Gagarin's 4 $\frac{3}{4}$ -ton Vostok 1 spacecraft was launched at 9:07 AM Moscow time on April 12, 1961, orbited the Earth once in 1 hour 29 minutes at a maximum altitude of 187 miles (301 kilometres), and landed at 10:55 AM in the Soviet Union. His spaceflight brought him immediate worldwide fame; he was awarded the Order of Lenin and given the titles of Hero of the Soviet Union and Pilot Cosmonaut of the Soviet Union. Monuments were raised to him and streets renamed in his honour across the Soviet Union.

He never went into space again but took an active part in training other cosmonauts. He

Gagarin, 1961  
Tass—Sovfoto

made several tours to other nations following his historic flight, and from 1962 he served as a deputy to the Supreme Soviet. Gagarin was killed with another pilot in the crash of a two-seat jet aircraft while on what was described as a routine training flight. His ashes

were placed in a niche in the Kremlin wall. After his death in 1968 the town of Gzhatsk was renamed Gagarin.

**gag** (instrument): *see* gauge.

**Gage, Matilda Joslyn**, *née* JOSLYN (b. March 25, 1826, Cicero, N.Y., U.S.—d. March 18, 1898, Chicago), U.S. women's rights advocate who helped to lead and publicize the U.S. suffrage movement.

Gage, who was married to Henry H. Gage, a merchant, in 1845, settled in Fayetteville, N.Y. She joined the National Woman Suffrage Association in 1869, and in 1875 she became president of both the national and New York state organizations. She subsequently spoke before state legislative and U.S. congressional committees and political conventions on behalf of women's rights. From 1878 to 1881, she also published the *National Citizen and Ballot Box*, the newspaper of the National Woman Suffrage Association.

In 1890, believing that mainstream suffragists were too conservative, Gage founded the Woman's National Liberal Union, a group dedicated to the separation of church and state.

Her most important publication was the monumental *History of Woman Suffrage*, with Susan B. Anthony and Elizabeth Cady Stanton (1881–87); she also wrote *Woman, Church and the State* (1893) and several feminist pamphlets.

**Gage, Thomas** (b. 1721, Firl, Sussex, Eng.—d. April 2, 1787, England), British general who successfully commanded all British forces in

Thomas Gage, pastel portrait by an unknown artist, in the State House, Boston  
By courtesy of the State Library of Massachusetts, Boston

North America for more than 10 years (1763–74) but failed to stem the tide of rebellion as military governor of Massachusetts (1774–75) at the outbreak of the American Revolution.

Gage's military career in North America began in 1754, when he sailed with his regiment to serve in the last French and Indian War (1756–63). He participated in Gen. Edward Braddock's disastrous campaign in western Pennsylvania (1754) and in the successful operation against Quebec (1759–60). He was thereupon made governor of Montreal (1760) and promoted to major general (1761).

In 1763 Gage was appointed commander in chief of all British forces in North America—the most important and influential post in the colonies. Headquartered in New York, he ran a vast military machine of more than 50 garrisons and stations stretching from Newfoundland to Florida and from Bermuda to the Mississippi. He exhibited both patience and tact in handling matters of diplomacy, trade, communication, Indian relations, and western boundaries. His great failure, however, was in his assessment of the burgeoning independence movement. As the main permanent adviser to the mother country in that period, he sent critical and unsympathetic reports that did much to harden the attitude of successive ministries toward the colonies.

When resistance turned violent at the Boston Tea Party (1773), Gage was instrumental in shaping Parliament's retaliatory Intolerable

(Coercive) Acts (1774), by which the port of Boston was closed until the destroyed tea should be paid for. He was largely responsible for inclusion of the inflammatory provision for quartering of soldiers in private homes and of the Massachusetts Government Act, by which colonial democratic institutions were superseded by a British military government. Thus Gage is chiefly remembered in the U.S. as the protagonist of the British cause while he served as military governor in Massachusetts from 1774 to 1775. In this capacity, he ordered the march of the redcoats on Lexington and Concord (April 1775), which was intended to uncover ammunition caches and to capture the leading Revolutionary agitator, Samuel Adams, who escaped. This unfortunate manoeuvre signalled the start of the American Revolution; after the equally disastrous Battle of Bunker Hill in June, Gage was succeeded by Gen. Sir William Howe. He soon returned to England and was commissioned a full general in 1782.

**Gager, Friedrich (Ludwig Balduin Karl Moritz), Freiherr von** (baron of) (b. Oct. 24, 1794, Weilburg, near Mainz—d. April 20, 1848, near Kandern, Baden), Hans Christoph von Gager's eldest son, a German soldier and administrator, and military commander of several Dutch provinces, who served as chief of staff during the wars against the Belgian rebels opposing Dutch rule. Returning to Germany, he led the fight against the republican revolutionaries in Baden in 1848.

Interrupted in his studies at Göttingen by Napoleon's temporary return to power in 1815, Gager fought and was wounded at Waterloo. Finishing his education at Heidelberg, he joined the Burschenschaft (German nationalist student movement), whose interests in German unification he was to share for the rest of his life. Gager then entered the Dutch Army, eventually becoming chief of the general staff and serving under Prince Bernhard of Weimar in the unsuccessful attempt to suppress the Belgian revolt (1830–31). Twice he was military commander, first of North Holland (1842–44), then, after a journey to the Dutch East Indies and around the world, of South Holland, a post he held simultaneously with his governorship of The Hague. Returning to Germany at the outbreak of the 1848 revolution, he led the army against the rebels in Baden but was killed during the first encounter.

**Gager, Hans Christoph, Freiherr von** (baron of) (b. Jan. 25, 1766, Kleinriedesheim, near Worms—d. Oct. 22, 1852, Hornau, near Höchst, Ger.), conservative German administrator, patriotic politician, and writer who unsuccessfully called for arming the entire German nation during the French Revolutionary Wars. He represented The Netherlands at the Congress of Vienna (1814–15) and favoured restoring the Holy Roman Empire to protect Germany's smaller principalities from the two large states, Austria and Prussia.

Educated at Leipzig and Göttingen, Gager entered the Nassau-Weilburg administration (1786), rising rapidly to chief minister. As Nassau's envoy to Paris, he secured (1806) additional territories for his principality within the Confederation of the Rhine, the league of German princes sponsored by Napoleon. After leaving the Nassau administration in 1811, he became foreign policy adviser to the Austrian archduke John. In 1813 the Prussian minister, Karl, Freiherr vom Stein, appointed Gager to the administrative council for the reconquered Prussian lands in western Germany, and in 1814 he became administrator of the Orange principalities. As the Netherlands' envoy at the Congress of Vienna, Gager failed in his attempts to tie these ter-

ritories closer to Germany and to restore the old Holy Roman Empire (dissolved in 1806). After the Battle of Waterloo (1815) he unsuccessfully championed the return of Alsace to Germany. Always an advocate of the rights of small states, Gagern was the representative of the Orange principality of Luxembourg at the German Bundestag (diet) from 1816 to 1818. In 1820 he was elected to the lower house of Hesse-Darmstadt, and in 1829 he became a lifelong member of that state's upper house.

**Gagern, (Wilhelm) Heinrich (August), Freiherr von** (baron of) (b. Aug. 20, 1799, Bayreuth, Ger.—d. May 22, 1880, Darmstadt, Hesse-Darmstadt), second son of Hans Christoph von Gagern, liberal, anti-Austrian German politician and president of the 1848–

Heinrich Gagern, detail from a lithograph by Johann Heinrich Hasselhorst, 1825

49 Frankfurt National Assembly, who was one of the leading spokesmen for the Kleindeutsch (Little German) solution to German unification before and during the 1848 revolution.

Wounded at Waterloo at the age of 16, Gagern studied in Heidelberg, Göttingen, and Jena. A liberal nationalist, he was instrumental in founding the Allgemeine Deutsche Burschenschaft, a student organization dedicated to the unification of Germany. He entered the Hesse-Darmstadt civil service in 1821 and served in the Landtag (lower house) from 1832 to 1836. Reentering politics in 1847, he became chief minister of Hesse-Darmstadt in March 1848. Gagern's role in the revolutionary Vorparlament (pre-parliament) was distinguished, but on May 19, 1848, he was elected president of the national assembly at Frankfurt. He secured the election of the Austrian archduke John as German regent and attempted to persuade Prussia to play the chief role in a unified Germany without eliminating Austria altogether. His proposal to offer the imperial crown to Frederick William IV of Prussia was finally accepted by the assembly, but the Prussian monarch's refusal destroyed his hopes. Gagern left Frankfurt when Archduke John dissolved the assembly on May 10, 1849. Retiring from politics, he served in the German Army against Denmark (1850). Later, he turned to Austria and by 1862 had come to favour the Austria-oriented Grossdeutsch (Greater German) solution. From 1864 to 1872 he served as Hessian minister to Vienna. When Gagern died in 1880, he was a forgotten man.

**Gagern, Maximilian (Joseph Ludwig) Freiherr von** (baron of) (b. March 25, 1810, Weilburg, Ger.—d. Oct. 17, 1889, Vienna), 10th son of Hans Christoph, liberal Dutch and German diplomat and politician, who played a prominent part in the German Revolution of 1848, attempting to institute the Kleindeutsch ("small German") solution to German unification, which aimed at excluding Austria's non-German territories.

Gagern, like his two prominent brothers, a nationalist and member of the Pan-German student Burschenschaft, was elected to the 1848 Frankfurt national assembly, where he served as vice president of the constitutional committee and undersecretary of state in the German Reich ministry of foreign affairs. In the spring of 1849 he led the unsuccessful "Gagern" mission, which tried to persuade the German princes to offer the imperial crown to the Prussian king Frederick William IV. Disillusioned with Prussia and the failure of the Kleindeutsch solution to German unification, Gagern entered the Austrian foreign service in 1855 but never again held a significant post.

**Gagliano, Marco da** (b. c. 1575, Gagliano, Kingdom of Naples—d. Feb. 24, 1642, Florence), one of the earliest composers of Italian opera.

Gagliano worked in Florence (c. 1608–25) as organist to Cosimo II de' Medici. He staged his first opera, *Dafne*, at Mantua in 1608. *Il Medoro*, composed with Jacopo Peri (1619), is lost; *La Flora* was produced in 1628. Gagliano followed the monodic recitative (melodic, half-spoken, half-sung) style of the Florentine Camerata, whose members sought to revive ancient Greek music and drama and produced the earliest operas. His recitative is musically richer than that of his contemporaries Peri and Giulio Caccini, and he provides a greater variety of set numbers. His works were eclipsed, however, by Monteverdi's *Orfeo*. He also published sacred music and madrigals between 1594 and 1630.

**Gagnoa**, town, administrative headquarters (since 1969) of Gagnoa *département*, southern Ivory Coast. It is the chief collecting point for a forest region that sends coffee, cocoa, and timber (sipo, mahogany) to the coast for export and is a major market centre (rice, bananas, and yams) among the Bete and Gagu (Gagou) peoples. A paved road connects Gagnoa with Abidjan, the Ivory Coast's capital. The town is the site of the government's first rural technical institute (1961), a labour court, a sawmill, and a model housing project. Metalworking is a traditional art among the local Bete, and there are bauxite deposits in the vicinity. Gagnoa has both Roman Catholic and Protestant churches and is the seat of a Catholic diocese. Pop. (1988) town, 85,563; *département*, 276,217.

**Gāhaḍavāla DYNASTY**, one of the many ruling families of North India on the eve of the Muslim conquests in the 12th–13th century. Its history, ranging between the second half of the 11th century and the mid-13th century, illustrates all the features of early medieval North Indian polity—dynastic hostilities and alliances, feudal-state structure, absolute dependence on Brahminical social ideology, and vulnerability in the face of external aggressions.

The family, perhaps originating in the Vārānasi-Ayodhyā area in Uttar Pradesh, later came to be associated with Kanauj, which had become one of the most crucial political centres in India. The majority of the Gāhaḍavāla epigraphic records were discovered in Uttar Pradesh and issued from Vārānasi. The dynastic power became gradually consolidated in the period of the first three rulers: Yaśovi-Graha, Mahicandra, and Candradeva (c. 1089–1103). By the period of Candradeva, the Gāhaḍavālas had taken control of Vārānasi, Ayodhyā, Kanauj, and Indrasthāniyaka (modern Delhi) and expanded all over Uttar Pradesh—sometimes at the expense of such powers as the Kalacuri. The Gāhaḍavālas sought to ward off the growing menace of Muslim incursions by expedient alliances and the payment of tributes, at least until the period of Candradeva's son Madanapala (reigned c. 1104–13), who was, in all probability, the Kanauj king imprisoned and later released during the pe-

riod of Ghaznavid Sultan Mas'ūd III. Despite the regularity of Muslim attacks, which were at least temporarily repulsed by Govindacandra (reigned c. 1113–15), the Gāhaḍavālas endeavoured to spread eastward; Govindacandra expanded to the Patna and Monghyr districts in Bihār, and in 1168–69 southwestern Bihār was being ruled by a feudatory of his son Vijayacandra (reigned c. 1155–69). Conventional accounts seem to suggest that Govindacandra had varied relations with an impressive number of Indian and non-Indian countries. Despite obvious exaggeration, hostilities with such powers as the Pālas, Senas, and the Kalacuris appear to be substantially factual.

The weakness of the internal structure of the Gāhaḍavāla kingdom was finally exposed late in the 12th century during the invasions of Mu'izz-ud-Dīn Muḥammad of Ghūr. Jayacandra (reigned c. 1170–94), who held Uttar Pradesh and parts of Bihār, had, according to bardic accounts, bitter enmity with the Cāhamānas of Rājasthān. He lost the battle and his life at Chandāwar (Etāwah district, Uttar Pradesh) in an encounter with Muḥammad of Ghūr. Although the Gāhaḍavālas lingered in Hariścandra's reign (c. 1194–?) in Kanauj, Jaunpur, and Mirzāpur districts until 1197, the buildup of Muslim expansion in the areas was steady through the early 13th century. Gāhaḍavāla royalty had an obscure death, sometime before the middle of the 13th century, at Nāgōd in central India, to which Aḍakkamallā, the last known Gāhaḍavāla, had escaped.

**Gahanbar**, in Zoroastrianism, any of six festivals, occurring at irregular intervals throughout the year, which celebrate the seasons and possibly the six stages in the creation of the world (the heavens, water, the earth, the vegetable world, the animal world, and man). Each lasting five days, the Gahanbars are: Maidhyāōizaremaya (Midspring), occurring in the month of Artavahisht, 41 days after the New Year; 60 days later is MaidhyoisHEMA (Midsummer), in the month of Tir; 75 days later, Paitishahya (Harvest-time), in the month of Shatvairō; 30 days later, Ayāthrima (possibly Time of Prosperity), in the month of Mitrā; 80 days later, Maidhyāirya (Midwinter), in the month of Din; and 75 days later, in the last five intercalary or Gatha days of the year, Hamaspathmaēdaya (Vernal Equinox).

Parsis observe the Gahanbar festivals in two stages. Four liturgical rites are first celebrated: the Afringān, being prayers of love or praise; the Bāj, prayers honouring *yazatas* (angels) or *fravashis* (guardian spirits); the Yasna, the central Zoroastrian rite, which includes the sacrifice of the sacred liquor, *haoma*; and the Pavi, prayers honouring God and his spirits, performed jointly by the priest and the faithful. A solemn feast then follows, in which the sacrificial offerings made in the preceding liturgies are consumed in ritual purity.

**Gahn, Johan Gottlieb** (b. Aug. 19, 1745, Voxna, near Söderhamn, Swed.—d. Dec. 8, 1818, Stockholm), Swedish mineralogist and crystallographer who discovered manganese in 1774. His failure to win fame may be related to the fact that he published little. He saved the notes, papers, and letters of his friend Carl Wilhelm Scheele, who discovered chlorine, but not his own. His essays on the balance and use of the blowpipe in analysis were recorded by Jöns Jacob Berzelius of Sweden. Gahn was assistant to Torbern Bergman, pioneer analytical chemist and physicist at the University of Uppsala. With Scheele, Gahn discovered phosphoric acid in bones and prepared phosphorus from bones. He improved copper-smelting processes and studied technical applications of minerals, opening new branches of industry. Gahnite (zinc spinel) is named for him. In 1784 he was appointed assessor of the mining college at Stockholm.

**gahnite**, the mineral zinc aluminum oxide, a member of the spinel (*q.v.*) series.

**Gai'wiio** (religious movement): see Handsome Lake cult.

**Gaikwar** DYNASTY (Indian history): see Gaekwar dynasty.

**Gailhard, John**, also called JEAN GAILHARD (fl. late 17th century), English author of an educational treatise on proper training for the English nobility that is noteworthy for its insights into the educational goals and techniques of the 17th-century English upper classes. Gailhard seems to have spent a number of years as tutor abroad to "several of the nobility and gentry," but nothing is really known of his life.

In his *Compleat Gentleman* (1678), Gailhard supported a broad curriculum, with the emphasis to be placed on education to develop character and noble bearing. In the second part of his two-part book, Gailhard detailed the educational advantages of foreign travel and prescribed a tutorial program for use abroad. He recommended prior knowledge of the native language, the keeping of a diary, regular religious devotions and Bible reading, physical exercise, and music. He suggested a three-year grand tour including stops at specific schools to learn the general principles of medicine and law.

**Gaillard, Château** (French: "Saucy Castle"), 12th-century castle built by Richard the Lion-Heart on the Andelys cliff overlooking the Seine River in France; substantial portions of it still stand. Château Gaillard, the strongest castle of its age, guarded the Seine River valley approach to Normandy. Skillfully designed and executed, with the base of the keep carved out of the natural rock, and with all approaches fronted with suitable towers and walls, it included an independent strongpoint

Château Gaillard, Les Andelys, Eure département, Fr. © Pierre Belzeaux/Photo Researchers

(the châtelet) protecting the eastern end of the height, with the main keep occupying the rest of the site.

In 1204 Philip II of France captured Château Gaillard after a siege of eight months. After isolating the fort by a double ditch, the French undermined and collapsed part of the châtelet and penetrated the main fortress through the latrines.

**Gaillard Cut**, also called CULEBRA CUT, Spanish CORTE DE CALEBRA, artificial channel in Panama forming a part of the Panama Canal. It is an excavated gorge, approximately 8 miles (13 km) long, across the Continental Divide. It is named for David du Bose Gaillard, the American engineer who planned its construction. Overflow from the Chagres River, which is dammed at Gatun to form Gatun Lake at the north end of the cut, is guided past Gamboa into the cut and south to the Pedro Miguel and Miraflores locks, which permit the descent of ships from the Caribbean Sea to the Pacific Ocean. The cut has to be constantly dredged because of its restricted channel (47 feet [14 m] deep and 500 feet [152 m] wide); Gamboa is the head-

quarters for all canal-dredging operations. The increasing size of ships and the carrying of hazardous cargo have increased the frequency with which navigation must be restricted to one-way traffic.

**Gaillardia**, genus of leafy, branching herbs of the family Asteraceae, native to North America. Several summer-blooming species are cultivated as garden ornamentals, especially blanketflower (*G. aristata*) and annual blanketflower (*G. pulchella*).

Annual blanketflower (*Gaillardia pulchella*) Gilbert S. Grant/Photo Researchers

They have purple disk flowers and yellow, orange, or white ray flowers with three or more teeth that give the plant a fringed appearance. Most have hairy leaves that are either grouped at the base of the plant or alternate along the stem.

**Gaillimh** (Ireland): see Galway.

**Gaines, Joseph**: see Gans, Joe.

**Gainesville**, city, seat (1853) of Alachua county, north-central Florida, U.S., about 70 miles (115 km) southwest of Jacksonville. Settlement developed around a trading post known as Hog Town (established 1830). In 1853 the city was laid out as the county seat and named for General Edmund Pendleton Gaines, a commander during the War of 1812. Gainesville was the site of some minor battles (1864) of the American Civil War and was temporarily occupied by Union forces.

The University of Florida (1905) has played a major role in the city's growth, and it remains the primary factor in the economy. Tourism and services (notably health care) are also important. Santa Fe Community College was opened there in 1966.

The city's cultural institutions include a symphony orchestra and a ballet company. The Florida Museum of Natural History and the Samuel P. Harn Museum of Art are on the university campus. The home of author Marjorie Kinnan Rawlings is preserved as a state historic site about 12 miles (20 km) southeast of the city. Devil's Millhopper State Geological Site and Paynes Prairie and San Felasco Hammock state preserves are all nearby. Ocala National Forest is about 25 miles (40 km) southeast. Inc. 1869. Pop. (2000) city, 95,447; Gainesville MSA, 181,596.

**Gainesville**, city, seat (1823) of Hall county, northeastern Georgia, U.S. It is located along Lake Sidney Lanier (which is impounded by Buford Dam on the Chattahoochee River), in the foothills of the southern Blue Ridge Mountains. Settled in 1818, it was named for General Edmund P. Gaines, who served in the War of 1812. Gainesville was virtually flattened by a tornado in 1936, but it recovered rapidly. Poultry raising is important, and diversified manufactures include textiles and apparel and industrial machinery. Gainesville is the site of Brenau University (1878, originally for women), the Riverside Military Academy (1907), and Gainesville (junior) College (opened 1966). It serves as headquarters for both Oconee and Chattahoochee national forests. Inc. 1821. Pop. (2000) 25,578.

**Gainsborough**, town, West Lindsey district, administrative and historic county of Lincolnshire, England. It stands on the River Trent, bordering Nottinghamshire. Gainsborough's early importance as a Saxon settlement was augmented when it became a military centre under the Danes (9th–11th centuries). Its position on a navigable river and a main road between London and the north of England soon added to its growth when it served as a market centre for the surrounding agricultural district. As a small North Sea river port, it deals mostly with barge traffic. Most of its industries are based on agricultural processing, but many general engineering and light industries connected with hosiery are also important. The town centre was renovated after World War II bombing damage; but some old buildings remain, notably the 18th-century parish church and the 15th-century Old Hall. Pop. (1991) 19,704.

**Gainsborough** (foaled 1915), English racehorse (Thoroughbred) who in 1918 won the British Triple Crown, consisting of the Two Thousand Guineas at Newmarket, the Derby at Epsom Downs, and the Saint Leger at Doncaster. Gainsborough, who was owned by Lady James Douglas, won the Two Thousand Guineas by 1½ lengths, becoming the first horse to win a classic race in the racing colours of a woman owner. He then won the Derby and the Saint Leger to complete the Triple Crown. Retired to stud, he attained worldwide importance as one of the top stallions whose blood lines are still influential. He died at the age of 30.

**Gainsborough, Thomas** (baptized May 14, 1727, Sudbury, Suffolk, Eng.—d. Aug. 2, 1788, London), portrait and landscape painter, the most versatile English painter of the 18th century. Some of his early portraits show the sitters grouped in a landscape ("Mr. and Mrs. Andrews," c. 1750). As he became famous and his sitters fashionable, he adopted a more formal manner that owed something to

"The Morning Walk," oil on canvas by Thomas Gainsborough, 1785; in the National Gallery, London. By courtesy of the trustees of the National Gallery, London

Anthony Van Dyck ("The Blue Boy," c. 1770). His landscapes are of idyllic scenes. During his last years he also painted seascapes and idealized full-size pictures of rustics and country children.

*Early life and Suffolk period.* Gainsborough was the youngest son of John Gainsborough, a maker of woolen goods. When he was 13,

he persuaded his father to send him to London to study on the strength of his promise at landscape. He worked as an assistant to Hubert Gravelot, a French painter and engraver and an important figure in London art circles at the time. From him Gainsborough learned something of the French Rococo idiom, which had a considerable influence on the development of his style. In 1746 in London he married Margaret Burr, the illegitimate daughter of the Duke of Beaufort. Soon afterward he returned to Suffolk and settled in Ipswich in 1752; his daughters Mary and Margaret were born in 1748 and 1752, respectively. In Ipswich Gainsborough met his first biographer, Philip Thicknesse. He early acquired some reputation as a portrait and landscape painter and made an adequate living.

Gainsborough declared that his first love was landscape and began to learn the language of this art from the Dutch 17th-century landscapists, who by 1740 were becoming popular with English collectors; his first landscapes were influenced by Jan Wynants. The earliest dated picture with a landscape background is a study of a bull terrier—"Bumper—A Bull Terrier" (1745; Sir Edward Bacon Collection, Raveningham, Norfolk), in which many of the details are taken straight from Wynants. But by 1748, when he painted "Cornard Wood," Jacob van Ruisdael had become the predominant influence; although it is full of naturalistic detail, Gainsborough probably never painted directly from nature. "The Charterhouse," one of his few topographical views, dates from the same year as "Cornard Wood" and in the subtle effect of light on various surfaces proclaims Dutch influence. In the background to "Mr. and Mrs. Andrews," he anticipates the realism of the great English landscapist of the next century, John Constable, but for the most part fancy held sway. In many of the early landscapes the influence of Rococo design learned from Gravelot is evident, together with a feeling for the French pastoral tradition. "The Woodcutter Courting a Milkmaid" is an Anglicized version of a French theme, which recalls compositions by Jean-Honoré Fragonard. Although Gainsborough preferred landscape, he knew he must paint portraits for economic reasons. The small heads painted in Suffolk, although sometimes rather stiff, are penetrating character studies delicately and freely pencilled, particularly the jaunty self-portrait in a cocked hat at Houghton. Gainsborough painted few full-length portraits in Suffolk. "Mr. William Woollaston," although an ambitious composition, is intimate and informal. The "Painter's Daughters Chasing a Butterfly," composed in the last years at Ipswich, is, in its easy naturalism and sympathetic understanding, one of the best English portraits of children.

As well as straight portraits, he painted in Suffolk a number of delightful spontaneous groups of small figures in landscapes closely related to conversation pieces. "Mr. and Mrs. Andrews," which has been described as the most English of English pictures, is set in a typical Suffolk landscape. "Lady and Gentleman in Landscape" is more Frenchified, with its vivacious Rococo rhythms, but "Heneage Lloyd and His Sister" is more stylized, the charming little figures being posed against a conventional background of steps and decorative urns.

**Bath period.** To obtain a wider public, Gainsborough moved in 1759 to Bath, where his studio was soon thronged with fashionable sitters. He moved in musical and theatrical circles, and among his friends were members of the Linley family, whose portraits he painted. At Bath he also met the actor David Garrick, for whom he had a profound admiration and whom he painted on many occasions.

His passion for music and the stage continued throughout his life. In the west country he visited many of the great houses and at Wilton fell under the spell of Anthony Van Dyck, the predominating influence in his later work. In spite of the demand for portraits, he continued to paint landscapes.

In 1761 he sent a portrait of Earl Nugent to the Society of Artists, and in the following year the first notice of his work appeared in the London press. Throughout the 1760s he exhibited regularly in London and in 1768 was elected a foundation member of the Royal Academy. Characteristically he never took much part in the deliberations.

After he moved to Bath, Gainsborough had less time for landscape and worked a good deal from memory, often drawing by candlelight from little model landscapes set up in his studio. About 1760 Peter Paul Rubens supplanted the Dutch painters as Gainsborough's chief love. This is particularly noticeable in "Peasants Returning from Market," with its rich colour and beautiful creamy pastel shades. The influence of Rubens is also apparent in "The Harvest Wagon" in the fluency of the drawing and the scale of the great beech trees so different from the stubby oaks of Suffolk. The idyllic scene is a perfect blend of the real and the ideal. The group in the cart is based on Rubens' "Descent from the Cross" (1611-14) in Antwerp cathedral, which Gainsborough copied.

In Bath, Gainsborough had to satisfy a more sophisticated clientele and adopted a more formal and elegant portrait style based largely on a study of Van Dyck at Wilton, where he made a free copy of Van Dyck's painting of the Pembroke family. By 1769, when he painted "Isabella Countess of Sefton," it is easy to see the refining influence of Van Dyck in the dignified simplicity of the design and the subtle muted colouring. One of Gainsborough's most famous pictures, "The Blue Boy," was probably painted in 1770. In painting this subject in Van Dyck dress, he was following an 18th-century fashion in painting, as well as doing homage to his hero. The influence of Van Dyck is most clearly seen in the more official portraits. "John, 4th Duke of Argyll" in his splendid robes is composed in the grand manner, and "Augustus John, Third Earl of Bristol" rivals Reynolds' portraits of the kind. Gainsborough preferred to paint his friends rather than public figures, and a group of portraits of the 1760s—Uvedale Price, Sir William St. Quinton, and Thomas Coward, all oldish men of strong character—illustrate Gainsborough's sense of humour and his individual approach to sympathetic sitters.

**London period.** In 1774 he moved to London and settled in part of Schomberg House in Pall Mall. Fairly soon he began to be noticed by the royal family and partly because of his informality and Tory politics was preferred by George III above the official court painter, Sir Joshua Reynolds. In 1781 he was commissioned to paint the King and Queen.

Gainsborough continued his landscape work. "The Watering Place" was described by Horace Walpole, the English man of letters, as in the style of Rubens, but it also has much of the classic calm of Claude Lorrain, whose etchings Gainsborough owned. In 1783 he made an expedition to the Lake District to see for himself the "wild" scenery extolled by the devotees of the picturesque. On his return he painted a number of mountain scenes that have analogies with the work of Gaspard Dughet, whose works were widely distributed in English country houses. Some sea pieces dating from the 1780s show a new kind of realism, harking back to the Dutch seascape tradition. During his last years Gainsborough was haunted by his nostalgia for Arcadia in the English countryside and painted a series of pictures of peasant life more ideal than real, for example, "The Cottage Door." But one

of the latest landscapes, "The Market Cart," is less idealized and more true to nature and looks forward to Constable in its treatment of the light breaking through the massive foliage.

Gainsborough was the only important English portrait painter to devote much time to landscape drawing. He composed a great many drawings in a variety of mediums including chalk, pen and wash, and watercolour, some of them varnished. He was always eager to find new papers and new techniques. He produced a magic lantern to give striking lighting effects; the box is still in the Victoria and Albert Museum, together with some of the slides. In addition Gainsborough made a series of soft-ground etchings and aquatints. He never sold his drawings and, although many of them are closely related to pictures, they are not studies in the ordinary sense but works of art in their own right.

Gainsborough was not methodical in keeping sitter books, and comparatively few of the portraits in the early years in London are dated. In 1777 he exhibited at the Royal Academy the well-known "Mrs. Graham," "C.F. Abel," "William Henry, Duke of Gloucester," and "Maria, Duchess of Gloucester," all deliberately glamorous and painted in richly heightened colour. "Queen Charlotte" is more restrained; the painting of the flounced white dress decorated with ribbons and laces makes her look every inch a queen. It is significant that Gainsborough, unlike most of his contemporaries, did not generally use drapery painters. In 1784 he quarrelled with the Academy because they insisted on hanging the "Three Eldest Princesses" at the normal height from the floor, which Gainsborough maintained was too high to appreciate his lightness of touch and delicate pencilling. In protest he withdrew the pictures he had intended for the exhibition and never showed again at the Academy.

In some of Gainsborough's later portraits of women, he dispensed with precise finish, and, without sacrificing the likeness, he concentrated on the general effect. "Mrs. Sheridan" melts into the landscape, while "Lady Bate Dudley," a symphony in blue and green, is an insubstantial form, almost an abstract. "Mrs. Siddons," on the other hand, shows that Gainsborough could still paint a splendid objective study. Few of the later male portraits are of a pronounced character, but exceptions are two particularly good pictures of musicians, "Johann Christian Fischer" and the unfinished "Lord Abingdon" (private collection).

A new venture in 1783 was "The Mall in St. James' Park," a park scene described by Horace Walpole as "all a flutter like a lady's fan." "The Morning Walk," with romanticized figures strolling in a landscape, is painted in the same spirit. The "fancy pictures" painted in the 1780s gave Gainsborough particular pleasure. They are full-sized, idealized portraits of country children and peasants painted from models—for example, "The Cottage Girl with a Bowl of Milk." The idea appeared in immature form in the little rustic Suffolk figures, and he may have been fired to exploit it further by seeing the 17th-century Spanish painter Bartolomé Murillo's "St. John," which he copied.

He died in 1788 and was buried in Kew churchyard.

**Assessment.** Of all the 18th-century English painters, Thomas Gainsborough was the most inventive and original, always prepared to experiment with new ideas and techniques, and yet he complained of his contemporary Sir Joshua Reynolds, "Damn him, how various he is." Gainsborough alone among the great portrait painters of the era also devoted serious attention to landscapes. Unlike Reynolds, he was no great believer in an academic tradition and laughed at the fashion for history painting; an instinctive painter, he delighted in the poetry of paint. In his racy letters Gainsborough

shows a warm-hearted and generous character and an independent mind. His comments on his own work and methods, as well as on some of the old masters, are very revealing and throw considerable light on contemporary views of art. (M.W.o.)

**MAJOR WORKS.** *Paintings.* Portraits: "Lady and Gentleman in Landscape" (1746; Louvre, Paris); "Mr. and Mrs. Andrews" (c. 1750; National Gallery, London); "Heneage Lloyd and His Sister" (c. 1750; Fitzwilliam Museum, Cambridge, Cambridgeshire); "Mr. William Woollaston" (late 1750s; Christchurch Mansion Museum, Ipswich, Suffolk); "Painter's Daughters Chasing a Butterfly" (c. 1758; National Gallery, London); "Ann Ford, Mrs. Philip Thicknesse" (1760; Cincinnati Art Museum, Ohio); "Maria, Duchess of Gloucester" (early 1760s; Los Angeles County Museum); "Gertrude, Lady Alston" (mid-1760s; Louvre); "John, 4th Duke of Argyll" (1767; Scottish National Portrait Gallery, Edinburgh); "Hon. Thomas Needham" (1768; Ascott House, Berkshire); "John, 10th Viscount Kilmorey" (c. 1768; Tate Gallery, London); "Augustus John, Third Earl of Bristol" (1768; National Trust, Ickworth, Suffolk); "Isabella, Countess of Sefton" (1769; Croxteth Hall, Lancashire); "The Blue Boy" (c. 1770; Henry E. Huntington Library and Art Gallery, San Marino, Calif.); "Penelope, Viscountess Ligonier" (1771; Henry E. Huntington Library and Art Gallery); "Dr. Ralph Schomberg" (1771-72; National Gallery, London); "The Linley Sisters—Mrs. Sheridan and Mrs. Tickell" (c. 1772; Dulwich College Picture Gallery, Dulwich); "William Henry, Duke of Gloucester" (c. 1775; Chewton Manor, North Somerset, Somerset); "Mrs. Graham" (c. 1777; National Gallery of Scotland, Edinburgh); "C. F. Abel" (1777; Henry E. Huntington Library and Art Gallery); "Johann Christian Fischer" (1780; Buckingham Palace, London); "Mrs. Robinson," popularly nicknamed "Perdita" (1781; Wallace Collection, London); "Queen Charlotte" (1781; Windsor Castle); "Lord Rodney" (1783; Earl of Rosebery Collection, Dalmeny, West Lothian); "Mrs. Siddons" (c. 1783; National Gallery, London); "Three Eldest Princesses," also called "Princess Charlotte and Her Two Sisters" (1784, painted for the Royal Academy but not exhibited; Buckingham Palace); "Mrs. Sheridan" (c. 1785; National Gallery of Art, Washington, D.C.); "Lady Bate Dudley" (1787; Lord Burton Collection, Needwood House, Derbyshire).

*Landscapes and "fancy pictures":* "The Charterhouse" (1748; Foundling Hospital, London); "Cornard Wood," popularly nicknamed "Gainsborough's Forest" (1748; National Gallery, London); "The Woodcutter Courting a Milkmaid" (1753; Duke of Bedford Collection, Woburn Abbey, Bedfordshire); "Peasants Returning from Market" (c. 1767; Toledo Museum of Art, Ohio); "The Harvest Wagon" (c. 1770; Barber Institute, Birmingham, Eng.); "The Watering Place" (1777; National Gallery, London); "The Cottage Door" (c. 1780; Henry E. Huntington Library and Art Gallery); "The Mall in St. James' Park" (1783; Frick Collection, New York City); "The Morning Walk" (1785; National Gallery, London); "The Cottage with Dog and Pitcher" (1785; Sir Alfred Beit Collection, Russborough, Co. Wicklow, Ire.); "The Cottage Girl with a Bowl of Milk" (1786; South African National Gallery, Cape Town); "The Market Cart" (1786; Tate Gallery); "The Wood Gatherers," also known as "Cottage Children" (1787; Metropolitan Museum of Art, New York City); "Boy with a Cat-Morning" (1787; Metropolitan Museum of Art).

**BIBLIOGRAPHY.** William T. Whitley, *Thomas Gainsborough* (1915), and Isabelle Worman, *Thomas Gainsborough: A Biography* (1976), are definitive biographies; Ellis Waterhouse, *Gainsborough* (1958), the most complete catalog of the paintings, fully illustrated with an important critical introductory essay; Mary Woodall (ed.), *The Letters of Thomas Gainsborough*, rev. ed. (1963); John Hayes, *The Drawings of Thomas Gainsborough*, 2 vol. (1970), the definitive work on the drawings with a catalog of 900 items, 462 illustrations, and a full up-to-date bibliography of Gainsborough literature.

**Gainsborough chair**, type of English armchair made in the mid-18th century. A wide

chair with a high back, it was normally upholstered in leather. The sides are open, and the short, upholstered arms are set well back from the seat, to which they are connected by a concave curving support. The arm supports and front legs are usually fluted or carved on the front face. The contemporary name was "French chair," a term that covered a variety of designs, the most elaborate based on French Rococo chairs of the Louis XV period.

**Gainza Paz, Alberto** (b. March 16, 1899, Buenos Aires—d. Dec. 26, 1977, Buenos Aires), editor of the influential Buenos Aires daily *La Prensa* who was exiled for his opposition to dictator Juan Perón.

Gainza Paz received a law degree from the National University at Buenos Aires in 1921 and joined the staff of *La Prensa* under the direction of his uncle, Ezequiel P. Paz, whom he succeeded in 1943. That same year the paper, which by then had gained worldwide prestige, was censured for criticizing the military government. In 1944 criticism of the regime's health program brought a five-day suspension. When Perón gained control of the government in the autumn of 1945, Gainza Paz was briefly arrested, an act which marked the beginning of a long campaign by the Perón regime to control the newspaper. In January 1951 the government-controlled newsdealers' union struck *La Prensa*, forcing it to suspend publication. Matters reached a critical point in March when the Congress ordered Gainza Paz, who had already left for Uruguay, jailed for contempt. *La Prensa* was confiscated in April 1951 and Gainza Paz did not resume management until after Perón was overthrown in 1956. The editor was regarded throughout the West as a symbol of the struggle for freedom of the press against official censorship. He was honoured for his promotion of hemispheric cooperation by the Americas Foundation at the October 1950 meeting of the Inter-American Press Association in New York.

**Gairdner, Lake**, largest of a group of shallow depressions west of Lake Torrens in central South Australia, 240 mi northwest of Adelaide. It measures 100 mi (160 km) long by 30 mi wide. Lying at the base of the Eyre Peninsula, the lake is a dry salt pan (playa) intermittently filled with water. Visited in 1857 almost simultaneously by Stephen Hack and Peter E. Warburton, it is named after Gordon Gairdner, former chief clerk in the Australian Department of the Colonial Office. The lake is surrounded by large sheep stations set amid sand hills and salt-bush vegetation.

**Gaiseric**, also spelled **GENSERIC** (d. 477), king of the Vandals and the Alani (428-477) who conquered a large part of Roman Africa and in 455 sacked Rome.

Gaiseric succeeded his brother Gunderic at a time when the Vandals were settled in Baetica (modern Andalusia, Spain). In May 428 Gaiseric transported all his people, purported by him to number 80,000, to Africa. Evidently he was invited to Africa by the governor, Count Bonifacius, who wished to use the military strength of the Vandals in his struggle against the imperial government.

Gaiseric caused great devastation as he moved eastward from the Strait of Gibraltar across Africa. He turned on Bonifacius, defeated his army in 430, and then crushed the joint forces of the Eastern and Western empires that had been sent against him. In 435 Gaiseric concluded a treaty with the Romans under which the Vandals retained Mauretania and part of Numidia and became *foederati* (allies under special treaty) of Rome.

In a surprise move on Oct. 19, 439, Gaiseric captured Carthage, thus throwing off Roman overlordship and striking a devastating blow at imperial power. In a 442 treaty with Rome the Vandals were recognized as the masters

of proconsular Africa, Byzacena, and part of Numidia. Gaiseric's fleet soon came to control much of the western Mediterranean, and he annexed the Balearic Islands, Sardinia, Corsica, and Sicily.

His most famous exploit, however, was the capture and plundering of Rome, June 455. Subsequently the King defeated two major efforts of the Romans to overthrow him, that of the emperor Majorian in 460 and that led by Basiliscus in 468. He was succeeded by his son Huneric.

**Gaitán, Jorge Eliécer** (b. Jan. 26, 1902, Bogotá—d. April 9, 1948, Bogotá), political leader who was considered a champion of the Colombian people and was revered as a martyr after his assassination.

Gaitán studied law at the National University of Colombia, Bogotá, and continued his studies in Rome. There he was greatly influenced by Benito Mussolini, paying careful attention to his techniques for arousing and organizing the populace. Returning to Colombia, he organized a short-lived party called Union Nacional Izquierdista Revolucionaria (Left Revolutionary National Union). His maiden speech as a congressman was a polemic attack on the plantations owned by the United Fruit Company (*q.v.*). He served as mayor of Bogotá (1936) and minister of education (1940).

In 1946, as the leader of the more radical factions of Liberals, he ran for the office of president in opposition to the official Liberal Party candidate Gabriel Turbay. That split among the Liberals gave the victory to the Conservative Party candidate Mariano Ospina Pérez. It was expected that Gaitán would be elected president in the next election, but he was killed by an assassin in 1948 during the International Conference of American States meeting in Bogotá. This murder led to a major popular uprising known as the *bogotazo* and exacerbated a period of civil unrest called the *violencia*.

**Gaitskell, Hugh (Todd Naylor)** (b. April 9, 1906, London—d. Jan. 18, 1963, London), British statesman, leader of the British Labour Party from December 1955 until his sudden death at the height of his influence.

After teaching political economy at the University of London, Gaitskell served through World War II in the Ministry of Economic Warfare. Entering the House of Commons in 1945, he was appointed minister of fuel and power in 1947, minister of state for economic

Gaitskell, 1955

Keystone

affairs in 1950, and chancellor of the exchequer (succeeding Sir Stafford Cripps) later the same year, leaving office when the Labour government was defeated in 1951.

Gaitskell was chosen to succeed Clement

Attlee as Labour leader in 1955, in preference to two more experienced candidates, Herbert Morrison and Aneurin Bevan. He seemed discredited in 1959 when his party lost the general election, and in 1960 when the party executive, which opposed unilateral nuclear disarmament, was defeated on that issue at the annual party conference. At the 1961 party conference, however, he secured a reversal of the decision on nuclear weapons and then was able to reunite the party. In 1962, again at the party conference, he made a notable speech opposing Great Britain's entry into the European Economic Community (Common Market), for which the Conservative government was unsuccessfully negotiating.

**Gaius**, also spelled CAIUS (ancient Roman personal name, or praenomen): *see under gens* or family name or honorific (e.g., under Catullus for Gaius Valerius Catullus), except as below.

**Gaius**, also spelled CAIUS (fl. AD 130–180), Roman jurist whose writings became authoritative under the late Roman Empire. In the Law of Citations (426), the Western emperor Valentinian III named him one of the five jurists (the others were Papinian, Ulpian, Modestinus, and Paulus) whose doctrines were to be followed by judges in deciding cases. The Institutes (Latin, *Institutiones*) of the Byzantine emperor Justinian I (reigned 527–565), which were intended to supersede Gaius' treatise of the same name, were modeled on the older work in style and content, numerous passages being copied verbatim.

Gaius' full name and most of his personal history are unknown. Besides the *Institutiones*, he wrote a commentary on the Twelve Tables (laws said to have been enacted about 450 BC, under the Roman monarchy), a treatise on the edicts of Roman magistrates, and several other works.

The *Institutiones* of Gaius, written about AD 161, comprise four books. The first concerns the legal status of persons; the second and third, property rights, including inheritance; and the fourth, forms of legal actions. The text was lost until 1816, when a manuscript, probably of the 5th century, was discovered at Verona, Italy. It was deciphered with great difficulty, because writings of St. Jerome had been superimposed on Gaius' words.

**Gaius, SAINT**, Gaius also spelled CAIUS (b. Dalmatia?—d. April 22?, 296, Rome; feast day April 22), pope from 283 (possibly December 17) to 296. Nothing about him is known with certainty. Supposedly a relative of the Roman emperor Diocletian, he conducted his pontificate at a period of Diocletian's reign when Christians were tacitly tolerated. Gaius is said, nevertheless, to have carried on his religious work for his last eight years concealed in the catacombs. His epitaph was found in the Cemetery of Calixtus.

**Gajah Mada**, also spelled GADJAH MADA (d. 1364), prime minister of the Majapahit Empire and a national hero in Indonesia. He is believed to have unified the entire archipelago. The principal poet of the era, Prapanca, eulogized Gajah Mada in an epic, and the first Indonesian university in Jogjakarta was named after him (1946).

No information is available on his early life, except that he was born a commoner. He rose to power on his intelligence, courage, and loyalty to King Jayanagara (1309–28) during a rebellion led by Kuti in 1319. He served as the head of the royal bodyguard that escorted King Jayanagara to Badander, when Kuti captured the capital of Majapahit. After finding a safe place for the King, he returned to the capital and spread the rumour that the King had been killed. He discovered that many officers

Terra-cotta head identified as Gajah Mada; in the Trawulan Site Museum, Indonesia

By courtesy of the Trawulan Museum, Indonesia

were upset by the King's supposed death and that Kuti was apparently unpopular among the people. Knowing, therefore, that the King still had loyal followers, Gajah Mada secretly organized a counterinsurrection, in which Kuti was killed and the King was restored. As a reward, Gajah Mada was appointed as the *patih* (minister) of Daha and, later, the *patih* of Daha and Janggala, a position that made him a member of the ruling elite. Prapanca, a court poet and historian, described Gajah Mada as "eloquent, sharp of speech, upright, and sober-minded."

Gajah Mada's loyalty to Jayanagara waned, however, when the King took possession of his wife. In 1328, when Jayanagara was ill, Gajah Mada instructed Tancha, the court physician, to kill the King during an operation. Upon the death of the King, Tancha was blamed and executed by Gajah Mada. Since the King had no son, his daughter Tribhuvana became ruler.

During the reign of Tribhuvana (1328–50), Gajah Mada gradually became the most powerful figure in Majapahit. In 1331 a rebellion took place in Sadeng (eastern Java). Gajah Mada immediately sent a military expedition to the area, but a minister of Majapahit named Kembar attempted to stop him from entering Sadeng. Gajah Mada broke the blockade and won the battle.

Upon his return, Gajah Mada was appointed as *mapatih*, or prime minister, of Majapahit. At the same time, he took a solemn oath before the council of ministers that he would not enjoy *palapa* (privileges of vacation or the revenue from his fief) before he conquered the whole archipelago for Majapahit. When Kembar and other ministers ridiculed this fantastic boast, Gajah Mada, with the help of the Queen, removed Kembar and his followers from office. In 1343, in accordance with his plans, Gajah Mada led a military expedition that conquered Bali.

Tribhuvana abdicated in 1350 and was succeeded by her son Hayam Wuruk, perhaps the best known king of Majapahit. During his reign, Majapahit reached the zenith of its power and controlled the whole of the Indonesian archipelago. The young King seemed content to leave the direction of affairs entirely in the hands of his prime minister.

The year after Hayam Wuruk's accession, Gajah Mada attempted to spread Majapahit influence to the western Java kingdom of Sunda. He sent a mission to Sunda expressing the wish of Hayam Wuruk to marry the daughter of the King of Sunda. The King consented and brought the Princess, together with some of his noblemen, to Majapahit. They camped in Bubad, north of the capital, in a large field where the wedding was supposed to take place. A disagreement ensued between Gajah Mada and the Sundanese king. The former wanted the King to surrender the Princess to Hayam Wuruk, but the King and his noblemen insisted that the Princess, as the queen of Majapahit, should have a status equal to that of Hayam Wuruk.

Gajah Mada brought in troops and intended

to decide the issue by force. The Sundanese noblemen preferred death to dishonour; instead of a happy wedding, a bloody massacre took place. The King of Sunda was killed, as were the Princess and the Sundanese noblemen. After the massacre, Sunda seems to have acknowledged the overlordship of Majapahit for a time but, ultimately, recovered its independence.

To glorify his power, Gajah Mada built a temple on the boundary line of the Singhasari kingdom in eastern Java to equate himself with the last king of Singhasari. It was under his patronage that Prapanca began the composition of *Nāgarakertāgama*, the epic of Majapahit. A law book that had a great significance in Javanese history was also compiled under his instructions.

Gajah Mada also played a major role in the direction of internal policy. He occupied numerous positions, including that of chief officer of the palace. The range of his activities was so great that, when he died, Hayam Wuruk found it necessary to appoint four ministers to take over the positions that had previously been the responsibility of Gajah Mada alone. Gajah Mada's death (1364) occurred under mysterious circumstances. Some writers claim that he was poisoned by Hayam Wuruk, who had come to fear his minister's power. The evidence, however, is inconclusive.

Gajah Mada's role in unifying the Indonesian archipelago caused early Indonesian nationalists to consider him a great national hero, and the first Indonesian university in Jogjakarta, established in 1946, was named after him.

**Gajdusek, D(aniel) Carleton** (b. Sept. 9, 1923, Yonkers, N.Y., U.S.), American physiologist and medical researcher, corecipient (with Baruch S. Blumberg) of the 1976 Nobel Prize for Physiology or Medicine for his work implicating slow-acting viruses as causal agents in degenerative neurological disorders.

Gajdusek graduated from the University of Rochester (N.Y.) in 1943. He received his M.D. from Harvard University in 1946 and was a fellow in pediatrics and infectious diseases at Harvard from 1949 to 1952. In the next three years he held positions at the Institute of Research of the Walter Reed Army Medical Center in Washington, D.C., and the Institut Pasteur, Tehran. It was in 1955, while he was a visiting investigator at the Walter and Eliza Hall Institute of Medical Research in Melbourne, Australia, that Gajdusek began the work which culminated in the Nobel Prize.

Gajdusek codiscovered and provided the first medical description of a unique central nervous system disorder occurring only among the Fore people of New Guinea and known by them as *kuru* ("trembling"). Living among the Fore, studying their language and culture, and performing autopsies on *kuru* victims, Gajdusek came to the conclusion that the disease was transmitted in the ritualistic eating of the brains of the deceased, a Fore funeral custom. Gajdusek became the head of laboratories for virological and neurological research at the National Institutes of Health (NIH) in 1958. After years of further research, much of it conducted with his NIH colleague Clarence Gibbs, Jr., he postulated that the delayed onset of the disease could be attributed to a virus capable of extremely slow action or, perhaps, having the ability to remain dormant for

years. Gajdusek's study proved to have significant implications for research into the causes of multiple sclerosis, Parkinson's disease, and other little-understood degenerative neurological conditions.

In addition to his work in virology, Gajdusek was an expert in the fields of learning and behaviour, child growth and development in primitive cultures, genetics, immunology, and neurological patterning and learning.

**Gaki:** see Akutagawa Ryunosuke.

**gal**, unit of acceleration, named in honour of the 16th–17th-century Italian physicist and astronomer Galileo and used especially in measurements of gravity. One gal equals a change in rate of motion of one centimetre (0.3937 inch) per second per second.

**Gal Oya**, river, eastern Sri Lanka. It rises in the hill country east of Badulla and flows north and east past Inginiyagala to the Indian Ocean 10 miles (16 km) south of Lalmunai. The Gal Oya river is the main source feeding the Gal Oya scheme, a government program that dammed this and smaller rivers to create Senanayake Samudra—the largest tank (reservoir) in Sri Lanka, at Bintenne. The project has opened up 100,000 acres (40,000 hectares) of land to the cultivation of paddy, sugarcane, chilies, potatoes, and other crops throughout the eastern coast. The Gal Oya National Park (founded 1954) has an area of 198 square miles (512 square km) and a wide variety of wildlife, including bear, elephant, and leopard.

**galactic cluster**, in astronomy, any group of young stars held together by mutual gravitation (see star cluster).

**galactic coordinate**, in astronomy, galactic latitude or longitude. The two coordinates constitute a useful means of locating the relative positions and motions of components of the Milky Way Galaxy. Galactic latitude is measured in degrees north or south of the Galaxy's fundamental plane of symmetry. This plane is defined by the galactic equator, the great circle in the sky best fitting the plane of the Milky Way, as determined by a combination of optical and radio measurements. The galactic equator is inclined at about 62°36' of arc to the celestial equator, which is the projection of Earth's Equator into the sky.

Galactic longitude is measured in degrees eastward of an imaginary line running across the fundamental plane of the Galaxy and connecting Earth (assumed to be on that plane) with the probable position of the galactic centre in the constellation Sagittarius. Before 1958, galactic longitude was measured from an arbitrarily chosen point, an intersection of the galactic and celestial equators in the constellation Aquila. The development of radio astronomy and rediscussion of optical results led to a more accurate determination of the position of the galactic centre and its adoption in 1958 as the new zero point of longitude.

At the same time, the positions of the galactic poles and equator were redefined, with a change of less than 2° in the positions of the poles. The north galactic pole is now considered to be in the constellation Coma Berenices, at +90° galactic latitude, and with equatorial (Earth-based) coordinates of 12 hours 49 minutes right ascension, 27°24' north declination.

In the pre-1958 system, the point that is now defined as zero longitude was at longitude 327°41'. Latitude and longitude in the new system are symbolized  $b^{\text{gal}}$  and  $l^{\text{gal}}$ , respectively, to distinguish them from the pre-1958 latitude and longitude (symbols  $b$  and  $l$ ), which are still found in a number of catalogs and charts.

**galactic halo**, in astronomy, nearly spherical volume of thinly scattered stars, globular clusters of stars, and tenuous gas observed surrounding spiral galaxies, including the Milky Way—the galaxy in which the Earth is lo-

cated. The roughly spherical halo of the Milky Way is thought to have a radius of some 50,000 light-years (about  $5 \times 10^{17}$  kilometres), and its gas is a source of radio emission, particularly at the 21-centimetre wavelength (see 21-centimetre radiation).

**galactorrhoea**, excessive flow of milk from the breast, or lactation that is not associated with childbirth or nursing. The abnormal production of milk in women is usually due to excessive levels of estrogen in the body or to excessive production of prolactin, a hormone that is manufactured by the pituitary gland and that stimulates the production of milk. Galactorrhoea may also be caused by a tumour or other disorder occurring in the pituitary gland. The milk of a nursing mother who has galactorrhoea may be watery, whitish green in colour, and of poor quality.

In women, persistent lactation without suckling, which follows upon a recent pregnancy, is called the Chiari-Frommel syndrome. Galactorrhoea in a woman who has never been pregnant is termed the Ahumada-del Castillo, or the Argonz-del Castillo, syndrome. Such galactorrhoea appears to result from excesses of secretion from the pituitary eosinophils.

Galactorrhoea in women has been reported from a wide variety of other causes, including encephalitis, pituitary stalk section, various surgical procedures, pneumoencephalography, and chlorpromazine, reserpine, birth-control pill, progesterone, or other drug therapies.

Therapy for galactorrhoea includes removal of the cause, when it is known, and regulation of the patient's estrogen and progesterone production.

**galactose**, a member of a group of carbohydrates known as simple sugars (monosaccharides). It is usually found in nature combined with other sugars, as, for example, in lactose (milk sugar). Galactose is also found in complex carbohydrates (see polysaccharide) and in carbohydrate-containing lipids called glycolipids, which occur in the brain and other nervous tissues of most animals.

**galactose tolerance test**, also called BAUER'S TEST, procedure assessing liver function. The healthy liver is able to convert galactose, one type of sugar, to glucose, the major sugar in the body. In persons with liver disease, this ability is defective; the administration of galactose results in the persistence of abnormal levels of it in the blood for several hours and in the urinary excretion of abnormal amounts of galactose. This test has been advocated for the differential diagnosis between hepatocellular and obstructive jaundice. The test yields abnormal results in persons with hepatocellular jaundice, which is caused by injury to the liver cells, but normal results in persons with obstructive jaundice, which is caused by an impediment to the flow of bile from the liver to the digestive tract.

**galactosemia**, a hereditary defect in the metabolism of the sugar galactose, which is a constituent of lactose, the main carbohydrate of milk. Infants with this condition appear normal at birth, but, after a few days of milk feeding, they begin to vomit, become lethargic, fail to gain weight, and show an enlargement of the liver. Untreated infants who survive are usually malnourished and stunted in growth; cataracts in the eyes and mental retardation may also occur. When their urine is tested for sugars, galactose invariably is present. In all affected infants, the symptoms of galactosemia regress after milk and milk products are eliminated from their diet.

Normally, galactose is metabolized in the body to glucose, each step in the metabolic pathway being carried out by a specific organic catalyst, or enzyme. In galactosemia, the enzyme that catalyzes the second step, converting galactose-1-phosphate to glucose-1-phosphate, is not active. As a result of this

metabolic block, there is an accumulation of galactose-1-phosphate in body tissues, and this compound is believed to be the cause of the cataracts and liver damage. Galactose is present in the blood and urine of persons suffering from galactosemia, and there is decreased formation of glucose in the body, which may result in a lowering of the blood glucose level. The mental retardation that is sometimes observed in galactosemic children may be caused by the high galactose level, the low glucose level, or both. It has been estimated that hereditary intolerance to galactose occurs in approximately one in 18,000 infants.

Galactosemia is transmitted by an autosomal recessive gene. Unaffected carriers of the trait who mate can expect, on the basis of chance, to have one galactosemic child, two children who are unaffected but are carriers, and one normal child for each four children born. Reliable and simple tests are available to detect carriers of galactosemia and galactosemic newborn infants. The condition can be detected before birth by collecting sample fluid from the amniotic sac. When a lactose-galactose-free diet is initiated early in infancy and maintained during the first three years of life, the development of liver disease, cataracts, and mental retardation may usually be prevented. In time, an increased tolerance to galactose may develop.

**galago**, any of six species of small, arboreal primates, genus *Galago*, family Lorisidae, found in sub-Saharan African forests. Galagos are attractive gray, brown, or reddish- or yellowish-brown animals with large eyes and ears, long hind legs, soft woolly fur, and long tails. They are also characterized by the great elongation of the upper portion of the feet (tarsus) and by the ability to fold their ears. Galagos pass the day in sleep but are active at night, feeding on fruits, insects, and small birds. In the trees, galagos cling and leap about; the smaller forms, such as the bush baby (*G. senegalensis*), are extremely active and agile. When they descend to the ground they sit upright, and they move around by jumping with their hind legs like jerboas. Galagos range in length from about 12–16 centimetres (4½–6 inches), excluding the 18–20-centimetre tail, in Demidoff's dwarf galago, *Galago* (or *Galagoides*) *demidovii*, to about 30–37 cen-

Bush babies (*Galago senegalensis*)

George Holton—Photo Researchers

timetres, excluding the 42–47-centimetre tail, in the thick-tailed galago, *G. crassicaudatus*. Known gestation periods are about three to four months; the number of young is usually one or two.

**Galahad**, the pure knight in Arthurian romance, son of Lancelot du Lac and Elaine (daughter of Pelles), who achieved the vision of God through the Holy Grail. In the first romance treatments of the Grail story (e.g., Chrétien de Troyes's 12th-century *Conte du Graal*), Perceval was the Grail hero. But during the 13th century a new, austere spiritual significance was given to the Grail theme,

and a new Grail winner was required whose genealogy could be traced back to the House of David in the Old Testament. Galahad was, moreover, made the son of Lancelot so that an achievement inspired by earthly love (Lancelot inspired by Guinevere) could be set in contrast to that inspired by heavenly love (Galahad inspired by spiritual fervour). This theological version of the Grail story appeared in the *Queste del Saint Graal* ("Quest for the Holy Grail"), which forms part of the *Prose Lancelot*, or *Vulgate cycle*. The *Queste* shows signs of strong Cistercian influence, and similarities can be seen between it and the mystical doctrines of St. Bernard of Clairvaux. See also Grail.

**Galanthis** (Greek mythology): see Galinthias.

**Galapagos finch**, also called DARWIN'S FINCH, distinctive group of birds whose radiation into several ecological niches in the competition-free isolation of the Galapagos Islands and on Cocos Island gave the English naturalist Charles Darwin evidence for his thesis that "species are not immutable." The three genera (*Geospiza*, *Camarhynchus*, and *Certhidea*), including 14 species, usually are placed in the songbird family Fringillidae (order Passeriformes) and in a distinct subfamily, Geospizinae, but some authors place them in the

Galapagos finch (*Camarhynchus parvulus*)

Alan Root—Bruce Coleman Inc.

family Emberizidae. All are 10–20 cm (4–8 inches) long and of brownish or black coloration; they differ greatly, however, in the configuration of their bills, which are suited to their diverse feeding habits. Two species—the woodpecker finch (*Camarhynchus pallidus*) and the mangrove finch (*C. heliobates*)—use cactus spines to probe for grubs.

**Galapagos Islands**, Spanish ISLAS DE LOS GALÁPAGOS, officially ARCHIPIÉLAGO DE COLÓN ("Columbus Archipelago"), island group of the eastern Pacific Ocean, administratively a province of Ecuador. The Galapagos are a group of 19 islands with associated islets and rocks lying athwart the Equator 600 miles (1,000 km) west of the mainland of Ecuador. Their total land area of 3,086 square miles (7,994 square km) is scattered over some 23,000 square miles (59,500 square km) of ocean.

The Galapagos Islands are formed of lava piles and dotted with shield volcanoes; eruptions have occurred on several of the islands in the 20th century. The striking ruggedness of their landscape is accentuated by high volcanic mountains, craters, and cliffs. The largest of the islands, Isabela (Albemarle), is approximately 82 miles (132 km) long and constitutes more than half of the total land area of the archipelago. The highest point of the Galapagos Islands is Mount Azul, on Isabela Island, at 5,541 feet (1,689 m). The second largest island is Santa Cruz (Indefatigable).

The Galapagos Islands were discovered in 1535 by the bishop of Panama, Tomás de Berlanga, while he was en route to Peru.

Galapagos Islands

He named them Las Encantadas ("The Enchanted"). Sites on several of the islands have yielded Inca pottery fragments providing evidence of pre-Spanish occupation. Numerous Spanish voyagers stopped at the islands during the 16th century; in the late 17th century pirates used the islands as a hideout; and in the early 19th century freebooting gave way to whaling and seal hunting. The islands had been unclaimed for almost 300 years before colonization began on what is now Santa María Island in 1832, when Ecuador took official possession of the archipelago. The islands became internationally famous when visited in 1835 by the English naturalist Charles Darwin; their unusual fauna contributed to the formation of his ideas on natural selection.

The climate of the Galapagos Islands is characterized by low rainfall, low humidity, and relatively low air and water temperatures. The islands have about 700 species of higher plants, of which about 40 percent are endemic. The plant life shows close affinities to that of South and Central America. The archipelago's arid lowlands are covered by an open cactus forest. A transition zone at higher elevations is covered with a forest in which pisonia, fish fuddle, and guava trees dominate. The moist forest region above the transition zone is dominated by a *Scalesia* forest (a relict form of vegetation) with dense underbrush. The treeless upland zone is covered with ferns and grasses. The government of Ecuador made the Galapagos (in part) a wildlife sanctuary in 1935 and again in 1959. In 1968 the sanctuary became the Galapagos National Park, administered by Ecuador with the assistance of the Charles Darwin biological station, which was established on Santa Cruz Island to promote scientific studies and to protect the indigenous vegetation and animal life of the Galapagos.

The archipelago is renowned for its unusual animal life and takes its name from its giant land tortoises (the old Spanish word for which is *galápagos*), thought to have the longest life span of any creature on Earth. The close affinities to the fauna of South and Central America indicate that most of the islands' animals originated there. The difficulty of crossing the ocean, however, accounts for the paucity of animal life. Amphibians are lacking, reptiles are few, and endemic land mammals are represented by only seven rodents and two bats. Only about 80 species and subspecies of birds breed on the islands; most land birds are Galapagos, or Darwin's, finches.

Galapagos animal life is nevertheless of extreme scientific interest for several reasons, which include the following. First, there is a high percentage of endemic forms; all the rep-

tiles, with the exception of one night lizard, and most of the resident birds are endemic. Second, species have developed subspecies on the different islands. Third, the Galapagos finches have developed a multitude of adaptive types from one common ancestor. They differ mainly in beak shape and size. Fourth, there are many other types that have evolved by adaptation. The swimming marine iguanas, for example, which feed on seaweed and in some places cover the coastal rocks in hundreds, are unique. Another species of interest is the flightless cormorant. Fifth, the giant tortoises, which once were widespread on the continents but became extinct elsewhere, survive as a relic on the larger islands. In addition, species of Antarctic origin, such as penguins and fur seals, live on the islands side by side with tropical animals.

The islands' human inhabitants, mostly Ecuadorians, live in settlements on San Cristóbal, Santa María, Isabela, and Santa Cruz islands; some of the islands are virtually untouched by humans. Tourism, fishing, and agriculture are the main economic activities, with grouper, coffee, and cattle being exported. Pop. (2000 est.) 16,917.

**Galashiels**, town, Scottish Borders council area, southeastern Scotland. It is on Gala Water near its junction with the River Tweed, 33 miles (53 km) south-southeast of Edinburgh. The part of the town on the west bank of the Gala lies within the historic county of Selkirkshire, while the east bank belongs to the historic county of Roxburghshire. Woolen manufacture dates from the close of the 16th century, and the Scottish College of Textiles (1909) is the central institution for the industry that is now mainly confined to the weaving of tweeds and the making of knitwear. There are also other light industries. Galashiels was originally a village built for accommodation of pilgrims to Melrose Abbey, 4 miles (6.4 km) southeast, and was designated a burgh of barony in 1599. Nearby are two homes of the novelist Sir Walter Scott. Also nearby is an ancient Pictish earthwork, the Catrail, or Picts' Work Ditch. Pop. (1991) 13,753.

**Galați, județ** (county), eastern Romania, bounded on the east by Moldova. The county is bordered in the east by the Prut River and in the south and west by the Siret River, both of which drain southeastward. Amid the county's lowlands and rolling hills lies Lake Brateș, Romania's largest freshwater lake, near Galați city, the county capital. Machinery, iron products, textiles, and canned goods are produced in Galați and Tecuci. Galați city is Romania's leading producer of ships. Timber industries operate in Comești and Ghidigeni. Livestock raising and cereal growing are the major agricultural activities. An agricultural school and a museum of history and science are found in Tecuci. Remains of a 6th–5th-century-BC settlement and a Roman fortress are situated in Barboși village. Carpina and Ghimia villages are fishing resorts beside Lake Brateș. Galați has a university. Galați, Tecuci, and Tirgu Bujor are centres for highway and railroad connections. Area 1,709 square miles (4,425 square km). Pop. (1997 est.) 641,647.

**Galați**, German GALATZ, city, capital of Galați județ (county), southeastern Romania. An inland port about 120 miles (190 km) northeast of Bucharest, it is situated on an eminence among the marshes at the confluence of the Danube and Siret rivers, on the southwestern shore of Lake Brateș.

By the beginning of the 15th century a fishing village, referred to as "the village of Galați," was documented; a century later, there was a reference to Schela Galați (*schela* being an old word for the place where ships are moored for loading and unloading). The port was important for the Turks, who occupied it from the early 16th century until 1829. Its rapid

19th-century development was stimulated by the adoption of free-port status from 1837 to 1883. During World War II, German troops retreating from the Soviet Union in 1944 devastated the town and reduced the population, substantially Jewish, to less than half. Owing to the intensive rebuilding effort since then, Galați has large areas of modern buildings.

Galați is a centre of culture. The University of Galați was founded in 1948. The city has theatres, as well as museums of modern art, history, and natural science. Among historic buildings is the fortified Precista Church (15th century).

The city is one of the chief ports for Romanian imports and the leading exporter of timber. The country's largest shipyard is at Galați. Industries include metalworking and the production of chemicals, textiles, building materials, and foodstuffs. In the 1970s Romania's largest ironworks and steelworks were completed there. Pop. (1985 est.) 262,216.

**Galatia**, ancient district in central Anatolia that was occupied early in the 3rd century BC by Celtic tribes, whose bands of marauders created havoc among neighbouring Hellenistic states. Invited from Europe to participate in a Bithynian civil war (278 BC), the Gallic horde plagued western Anatolia until checked by the Seleucid king Antiochus I at the so-called Ele-

Galatia

From W. Shepherd, *Historical Atlas*, Harper & Row, Publishers (Barnes & Noble Books), New York; revision copyright © 1964 by Barnes and Noble, Inc.

phant Battle (275 BC). At that point the Celts, called Galatae (Galatians) by 3rd-century writers, settled in the territory to which they gave their name. The Galatians, having joined the Seleucids against Rome (winter 190–189 BC), brought upon themselves a Roman punitive expedition (189 BC) from which they never recovered. Passing successively under the rule of Pergamum and Pontus, Galatia became a Roman protectorate (85 BC) ruled by puppet kings. Though originally possessing a strong cultural identity, the Galatians by the 2nd century AD had become absorbed into the Hellenistic civilization of Anatolia.

**Galatians, The Letter of Paul to the**, also called the *EPISTLE OF ST. PAUL THE APOSTLE TO THE GALATIANS*, New Testament writing addressed to Christian churches (exact location uncertain) that were disturbed by a Judaizing faction within the early Christian church. The members of this faction taught that Christian converts were obliged to observe circumcision and other prescriptions of the Mosaic Law. They repudiated Paul's statements to the contrary by denying the legitimacy of his apostolic calling. In rebuttal, Paul vigorously defended his credentials as a true apostle of Jesus Christ and provided important autobiographical information in the process.

In the letter Paul reaffirms his former teaching that the Mosaic Law is obsolete and that a return to Jewish practices would therefore be regressive. Though Christians have a new freedom, they have no license to sin; rather, they assume a responsibility to live lives in accord with the Spirit of God. Historical problems have caused uncertainty about the date of the letter's composition.

**Galatz** (Romania): *see* Galați.

**Galaup, Jean-François de:** *see* La Pérouse, Jean-François de Galaup, comte de.

**galaxy**, any of the billions of systems of stars and interstellar matter that make up the Cosmos.

A brief treatment of galaxies follows. For full treatment, *see* MACROPAEDIA: Galaxies.

Galaxies vary considerably in size, composition, and structure, but nearly all of them are arranged in groups, or clusters, of from a few to as many as 10,000 members each. The diameters of galaxies are generally measured in tens of thousands of light-years. The distance between galaxies within a cluster averages approximately 1,000,000–2,000,000 light-years, and the spaces between clusters of galaxies may be a hundred times as great. Each galaxy is composed of innumerable stars—most likely from hundreds of million to more than a trillion stars. In many galaxies, as in the Milky Way Galaxy, clouds of interstellar gas and dust particles known as nebulas can be detected.

The majority of known galaxies fall into one of two major classes: spirals and ellipticals. Roughly 70 percent of the bright galaxies in the sky are of the spiral variety, including the Milky Way Galaxy.

A spiral galaxy has a main disk of stars 50,000 to 150,000 light-years in diameter and a thickness up to a tenth as great. Embedded in the disk are the spiral arms, winding out from the centre like those of a pinwheel. The arms contain the greatest concentration of a spiral galaxy's interstellar gas and dust, and it is in these regions that star formation can occur. Among newly formed stars are the occasional short-lived, highly luminous ones; their presence in the arms makes them conspicuous on telescopic photographs. Surrounding the central nucleus of a spiral galaxy is a large nuclear bulge, which is nearly spherical in most cases and may have a diameter of up to half that of the disk. Outside the nuclear bulge and disk is a sparse, more or less spherical halo of star clusters, individual stars, and perhaps other matter. The halo may extend far beyond the disk and contain most of the galaxy's mass.

Spiral galaxies are generally subdivided into "normal" and "barred" types. In the latter, the arms begin either from the ends of a straight bar of stars and interstellar matter passing through the nucleus or from a circular ring surrounding the bar, rather than from the nucleus. Spirals are still further subdivided according to three well-correlated parameters: the size of the nucleus, the tightness of the winding of the arms, and the smoothness of the arms.

Barred spiral galaxy (NGC 1300) in the constellation Eridanus

By courtesy of Mount Wilson and Palomar Observatories

An elliptical galaxy has a telescopic image that reveals a symmetrical distribution of stars in a spherical or spheroidal shape. Such galaxies range from the rare giant ellipticals, which extend several hundred thousand light-years across, to dwarf ellipticals of only a few

million stars. The dwarf ellipticals are by far the most common kind of galaxy, although none is conspicuous in the sky. The projected images of ellipticals range from nearly circular to extremely elongated. Their flattening, however, is not due to rotation, and it is not known whether their true shapes are oblate or prolate spheres.

A small number of galaxies do not fit neatly into the usual scheme, and they are classified as irregular. There are also some special classes, a few of which are considered here. The first of these are the S0 galaxies, which are usually found in rich clusters of galaxies. They resemble spirals but have no spiral arms, possibly because their interstellar matter is stripped away as they move through intracluster gas. A second type of unusual star system is the cD galaxy. Such galaxies are supergiant ellipticals that often occur at or near the centre of rich galactic clusters. They are thought to result from the merging, or fusion, of several galaxies that have collided. Active nuclei galaxies constitute one other notable class of unusual galaxies. Their central nuclei show evidence of spectacular or violent activity. These range from Seyfert galaxies to quasars, the latter generally believed to be exceedingly bright nuclei of very remote galaxies.

**Galba**, Latin in full *SERVIVS GALBA CAESAR AVGVSTVS*, original name *SERVIVS SVLPICIVS GALBA* (b. Dec. 24, 3 BC—d. Jan. 15, AD

Galba, marble bust, in the Uffizi, Florence

Alinari—Art Resource/EB Inc

69, Rome [Italy]), Roman emperor for seven months (AD 68–69). His administration was priggishly upright, though his advisers were allegedly corrupt.

Galba was the son of the consul Gaius Sulpicius Galba and Mumia Achaica, and in addition to great wealth and ancient lineage he enjoyed the favour of the emperors Augustus and Tiberius. He began his senatorial career before the normal age, became consul (AD 33), received command of the Upper German army (39), and served a proconsulship in Africa (45).

Galba was appointed governor of Nearer Spain in 60 and served in that post for eight years. In 68, believing that the emperor Nero was planning his assassination, Galba accepted (and perhaps even prompted) an invitation from Vindex, the governor of Lugdunensis in Gaul, to head a rebellion against Nero. He then recruited troops in Spain and built up a large following in many other regions of the empire, though Vindex himself was defeated in a battle with the Rhine armies. Nero, deserted by his imperial troops (Praetorian Guard), killed himself on June 9, 68, and Galba was formally accepted as emperor by the Senate. Upon his arrival in Rome as emperor,

Galba executed many highly placed Romans, including the praetorian prefect Nymphidius Sabinus, who had been responsible for his accession. His rewards to the Gallic states that had supported Vindex alienated the Lower Rhine army, which on Jan. 2, 69, proclaimed its commander, Vitellius, emperor. Galba had also refused to pay the Praetorians the reward that they claimed for having deserted Nero; and, when he adopted Lucius Piso Licinianus as his successor instead of the former governor of Lusitania, Otho, the latter won the support of the Praetorians, who then killed both Galba and Piso in the Forum.

**Galbraith, John Kenneth** (b. Oct. 15, 1908, Iona Station, Ont., Can.—d. April 29, 2006, Cambridge, Mass., U.S.), American economist and public servant known for his liberal views and for the high literary quality of his popular writings on public affairs.

After study at the University of Toronto (B.S., 1931) and the University of California at Berkeley (Ph.D., 1934), Galbraith, who became a U.S. citizen in 1937, taught successively at Harvard and Princeton universities until 1942. During World War II and the post-war period, he held a variety of governmental posts, resuming his academic career at Harvard (1948–75). He established himself as a politically active, liberal academician with a talent for communicating with the reading public. A key adviser to President John F. Kennedy, he served as ambassador to India (1961–63), returning to Harvard in 1963 but continuing his involvement in public affairs. In 1967–68 he served as national chairman of Americans for Democratic Action.

Galbraith's major works include *American Capitalism: The Concept of Countervailing Power* (1951), in which he questioned the devotion to the competitive ideal in industrial organization. In *The Affluent Society* (1958) he faulted the "conventional wisdom" of American economic policies and called for less emphasis on production and more attention to public services. In *The New Industrial State* (1967) he called for intellectual and political innovations to deal with the decline of competition in the American economy and envisaged a growing similarity between "managerial" capitalism and socialism. Among his many other works are *The Great Crash, 1929* (1955), *The Liberal Hour* (1960), *Ambassador's Journal* (1969), *A Life in Our Times: Memoirs* (1981), *The Anatomy of Power* (1983), *Economics in Perspective: A Critical History* (1987), and *The Culture of Contentment* (1992). He was awarded the Presidential Medal of Freedom in 1946 and in 2000.

**Galdan** (Mongol leader): see Dga'ldan.

**Galdhø Peak**, Norwegian Galdhøpiggen, highest mountain peak of Norway and the Scandinavian peninsula. It lies in the Jotunheim Mountains, western Oppland fylke (county), south-central Norway, and rises to 8,100 feet (2,469 m). The nearby Mount Glitter has a height of 8,045 feet (2,452 m). Galdhø was first climbed in 1850. Surrounded by glaciers and with a scenic view of other peaks, Galdhø is a focal point of Jotunheimen National Park (1980) and is a tourist mecca during the summer climbing season.

**gale**, air current that is stronger than a breeze; specifically a current of 28–55 knots (50–102 kilometres per hour), corresponding to force numbers 7 to 10 on the Beaufort scale (*q.v.*).

**Gale, Zona** (b. Aug. 26, 1874, Portage, Wis., U.S.—d. Dec. 27, 1938, Chicago, Ill.), American novelist and playwright whose *Miss Lulu Bett* (1920) established her as a realistic chronicler of Midwestern village life.

Gale graduated from the University of Wis-

consin in 1895 and received her M.A. there in 1899. After two years with various Milwaukee newspapers she became, in 1901, a reporter for the *New York World*. After the publication of her first short story, in 1903, she gave her full time to writing.

Gale's books include *Friendship Village* (1908), *When I Was a Little Girl* (1913), *Heart's Kindred* (1915), *A Daughter of the Morning* (1917), *Birth* (1918), *Faint Perfume* (1923), and *Preface to a Life* (1926). Her early writings were sentimental evocations of the virtues of small-town life and fall within the local-colour tradition. But her later writings reveal her interest in progressive causes and are increasingly critical of small-town provincialism. The dramatization of *Miss Lulu Bett*, a study of a spinster's attempts at self-assertion in the face of a constricting social environment, won Gale the Pulitzer Prize in 1921. Her other plays were *Mister Pitt* (1925), a dramatization of *Birth*, and *Evening Clothes* (1932).

**Galen** OF PERGAMUM, byname of Greek GALENOS, Latin GALENUS (b. AD 129, Pergamum, Mysia, Anatolia [now Bergama, Tur.]—d. c. 216), Greek physician, writer, and philosopher who exercised a dominant influence on medical theory and practice in Europe from the Middle Ages until the mid-17th century. His authority in the Byzantine world and the Muslim Middle East was similarly long-lived.

*Early life and training.* The son of a wealthy architect, Galen was educated as a philosopher and man of letters. His hometown, Pergamum, was the site of a magnificent shrine of the healing god, Asclepius, that was visited by many distinguished figures of the Roman Empire for cures. When Galen was 16, he changed his career to that of medicine, which he studied at Pergamum, at Smyrna (modern İzmir, Tur.), and finally at Alexandria in Egypt, which was the greatest medical centre of the ancient world. After more than a decade of study, he returned in AD 157 to Pergamum, where he served as chief physician to the troop of gladiators maintained by the high priest of Asia.

In 162 the ambitious Galen moved to Rome. There he quickly rose in the medical profession owing to his public demonstrations of anatomy, his successes with rich and influential patients whom other doctors had pronounced incurable, his enormous learning, and the rhetorical skills he displayed in public debates. Galen's wealthy background, social contacts, and a friendship with his old philosophy teacher Eudemus further enhanced his reputation as a philosopher and physician.

Galen abruptly ended his sojourn in the capital in 166. Although he claimed that the intolerable envy of his colleagues prompted his return to Pergamum, an impending plague in Rome was probably a more compelling reason. In 168–169, however, he was called by the joint emperors Lucius Verus and Marcus Aurelius to accompany them on a military campaign in northern Italy. After Verus' sudden death in 169, Galen returned to Rome, where he served Marcus Aurelius and the later emperors Commodus and Septimius Severus as a physician. Galen's final works were written after 207, which suggests that his Arab biographers were correct in their claim that he died at age 87, in 216/217.

*Anatomical and medical studies.* Galen regarded anatomy as the foundation of medical knowledge, and he frequently dissected and experimented on such lower animals as the Barbary ape (or African monkey), pigs, sheep, and goats. Galen's advocacy of dissection, both to improve surgical skills and for research purposes, formed part of his self-promotion, but there is no doubt that he was an accurate observer. He distinguished seven pairs of cranial nerves, described the valves of the heart, and observed the structural differences between arteries and veins. One of his most im-

portant demonstrations was that the arteries carry blood, not air, as had been taught for 400 years. Notable also were his vivisection experiments, such as tying off the recurrent laryngeal nerve to show that the brain controls the voice, performing a series of transections of the spinal cord to establish the functions of the spinal nerves, and tying off the ureters to demonstrate kidney and bladder functions. Galen was seriously hampered by the prevailing social taboo against dissecting human corpses, however, and the inferences he made about human anatomy based on his dissections of animals often led him into errors. His anatomy of the uterus, for example, is largely that of the dog's.

Galen's physiology was a mixture of ideas taken from the philosophers Plato and Aristotle as well as from the physician Hippocrates, whom Galen revered as the fount of all medical learning. Galen viewed the body as consisting of three connected systems: the brain and nerves, which are responsible for sensation and thought; the heart and arteries, responsible for life-giving energy; and the liver and veins, responsible for nutrition and growth. According to Galen, blood is formed in the liver and is then carried by the veins to all parts of the body, where it is used up as nutriment or is transformed into flesh and other substances. A small amount of blood seeps through the lungs between the pulmonary artery and pulmonary veins, thereby becoming mixed with air, and then seeps from the right to the left ventricle of the heart through minute pores in the wall separating the two chambers. A small proportion of this blood is further refined in a network of nerves at the base of the skull (in reality found only in ungulates) and the brain to make psychic pneuma, a subtle material that is the vehicle of sensation. Galen's physiological theory proved extremely seductive, and few possessed the skills needed to challenge it in succeeding centuries.

Building on earlier Hippocratic conceptions, Galen believed that human health requires an equilibrium between the four main bodily fluids, or humours—blood, yellow bile, black bile, and phlegm. Each of the humours is built up from the four elements and displays two of the four primary qualities: hot, cold, wet, and dry. Unlike Hippocrates, Galen argued that humoral imbalances can be located in specific organs, as well as in the body as a whole. This modification of the theory allowed doctors to make more precise diagnoses and to prescribe specific remedies to restore the body's balance. As a continuation of earlier Hippocratic conceptions, Galenic physiology became a powerful influence in medicine for the next 1,400 years.

Galen was both a universal genius and a prolific writer: about 300 titles of works by him are known, of which about 150 survive wholly or in part. He was perpetually inquisitive, even in areas remote from medicine, such as linguistics, and he was an important logician who wrote major studies of scientific method. Galen was also a skilled polemicist and an incorrigible publicist of his own genius, and these traits, combined with the enormous range of his writings, help to explain his subsequent fame and influence.

*Influence.* Galen's writings achieved wide circulation during his lifetime, and copies of some of his works survive that were written within a generation of his death. By AD 500 his works were being taught and summarized at Alexandria, and his theories were already crowding out those of others in the medical handbooks of the Byzantine world. Greek manuscripts began to be collected and translated by enlightened Arabs in the 9th century, and in about 850 Hunayn ibn Ishāq, an Arab physician at the court of Baghdad, prepared an annotated list of 129 works of Galen that he and his followers had translated from Greek into Arabic or Syriac. Learned medicine in

the Arabic world thus became heavily based upon the commentary, exposition, and understanding of Galen.

Galen's influence was initially almost negligible in western Europe except for drug recipes, but from the late 11th century Hunayn's translations, commentaries on them by Arab physicians, and sometimes the original Greek writings themselves were translated into Latin. These Latin versions came to form the basis of medical education in the new medieval universities. From about 1490, Italian humanists felt the need to prepare new Latin versions of Galen directly from Greek manuscripts in order to free his texts from medieval preconceptions and misunderstandings. Galen's works were first printed in Greek in their entirety in 1525, and printings in Latin swiftly followed. These texts offered a different picture from that of the Middle Ages, one that emphasized Galen as a clinician, a diagnostician, and above all, an anatomist. His new followers stressed his methodical techniques of identifying and curing illness, his independent judgment, and his cautious empiricism. Galen's injunctions to investigate the body were eagerly followed, since physicians wished to repeat the experiments and observations that he had recorded. Paradoxically, this soon led to the overthrow of Galen's authority as an anatomist. In 1543 the Flemish physician Andreas Vesalius showed that Galen's anatomy of the body was more animal than human in some of its aspects, and it became clear that Galen and his medieval followers had made many errors. Galen's notions of physiology, by contrast, lasted for a further century, until the English physician William Harvey correctly explained the circulation of the blood. The renewal and then the overthrow of the Galenic tradition in the Renaissance had been an important element in the rise of modern science, however. (V.Nu.)

**BIBLIOGRAPHY.** The selection of passages in Arthur J. Brock, *Greek Medicine, Being Extracts Illustrative of Medical Writers from Hippocrates to Galen* (1929, reprinted 1977), still offers the best sampling of Galen's own writings.

Owsei Temkin, *Galenism: Rise and Decline of a Medical Philosophy* (1973), is fundamental. Rudolph E. Siegel, *Galen's System of Physiology and Medicine* (1968), *Galen on Sense Perception* (1970), and *Galen on Psychology, Psychopathology, and Function and Diseases of the Nervous System* (1973), attempt to reconcile Galen with modern medicine. Shorter accounts include sections in two essays by Vivian Nutton, "Roman Medicine, 250 BC to AD 200," and "Medicine in Late Antiquity and the Early Middle Ages," chapters 3-4 in Laurence Conrad et al., *The Western Medical Tradition: 800-1800 A.D.* (1995); and Simon Swain, "Galen," chapter 11 in his *Hellenism and Empire: Language, Classicism, and Power in the Greek World, AD 50-250* (1996), pp. 357-379.

**Galen, Clemens August, Graf (Count) von** (b. March 16, 1878, Dinklage, Oldenburg [Germany]—d. March 22, 1946, Münster, W.Ger.), German Roman Catholic bishop of Münster who was noted for his public opposition to Nazism.

Galen was ordained in 1904 at Münster, where, as a priest at St. Lambert's, he published his *Pest des Laizismus und ihre Erscheinungsformen* (1932; "The Plague of Laicism and Its Manifestations"), deploring what he considered to be the godlessness of post-World War I Germany. He was made bishop of Münster in 1933 and became a powerful critic of Adolf Hitler's regime.

Galen's fight against the Nazis, particularly their racism and totalitarianism, began on Easter 1934 and continued unrelentingly. He frequently complained directly to Hitler when he felt the German dictator had violated the concordat he had signed in 1933 with the Vatican. When the Oldenburg Nazis removed all crucifixes from the schools (November 1936), Galen's protest sparked a public demonstra-

tion, and the order was canceled. In July and August 1941, Galen preached against the general lawlessness of the Gestapo, the confiscation of religious property, and the killing of "unproductive" sick and old; as a result, the "mercy killings" were temporarily halted. Documents discovered later showed that the Nazis were close to a decision to hang him but decided to wait until they achieved a victory in World War II. Galen was created a cardinal on Feb. 18, 1946.

**Galena**, city, seat (1827) of Jo Daviess county, northwestern Illinois, U.S. It lies along the Galena River (originally called Fever River), 4 miles (6 km) from the Mississippi River. Originally a frontier outpost known as Fever River Settlement, or The Point, it became an active mining centre and was laid out in 1826 and renamed Galena for the lead sulfide deposits that had been worked in the area since the early 1700s. It prospered as a port for Mississippi River traffic. By the 1860s lead mining and river commerce declined, as did the town.

As an example of a well-preserved antebellum Midwestern city, Galena has become a tourist centre, much of it designated an Illinois historic site. Historic buildings include the restored home of Ulysses S. Grant. The Galena/Jo Daviess County History Museum houses lead-mining relics and an American Civil War collection. Inc. 1835. Pop. (1994 est.) 3,810.

**galena**, also called **LEAD GLANCE**, a gray lead sulfide (PbS), the chief ore mineral of lead. One of the most widely distributed sulfide minerals, it occurs in many different types of deposits, often in metalliferous veins, as at Broken Hill, Australia; Coeur d'Alene, Idaho, U.S.; Clausthal Zellerfeld, Ger.; and Cornwall, Eng. Large deposits also occur as replacements of limestone or dolomite (e.g., at Santa Eulalia, Mex.). Some deposits (e.g., at Darwin, Calif.) are of contact-metamorphic origin. Galena is found in cavities and brecciated (fractured) zones in limestone and chert, as in the extensive Mississippi River valley deposits, where 90 percent of the U.S. production of lead is mined. The mineral has occasionally been observed as a replacement of organic matter, and sometimes occurs in coal beds. For detailed physical properties, see sulfide mineral (table).

Galena forms isometric crystals in which the ionic lattice is like that of sodium chloride. The mineral is easily weathered to secondary lead minerals, the upper part of galena deposits often containing cerussite, anglesite, and pyromorphite. Nodules of anglesite and cerussite with a banded structure and a galena core are common.

In many cases, galena contains silver and so is often mined as a source of silver as well as lead. Other commercially important minerals that frequently occur in close association with galena include antimony, copper, and zinc.

**Galerius**, in full **GAIUS GALERIUS VALERIUS MAXIMIANUS** (b. near Serdica, Thrace [now Sofia, Bulg.]—d. 311), Roman emperor from 305 to 311, notorious for his persecution of Christians.

Galerius was born of humble parentage and had a distinguished military career. On March 1, 293, he was nominated as caesar by the emperor Diocletian, who governed the Eastern part of the empire. After fighting hostile tribes along the Danube River for several years, Galerius assumed command of defensive operations against the Sāsānians in 297. After being defeated, he then won a decisive victory that increased his influence with Diocletian; evidently it was the staunchly pagan Galerius who persuaded the emperor to initiate the persecution of the Christians.

When Diocletian abdicated on May 1, 305, Galerius became augustus (senior emperor)

of the East, ruling the Balkans and Anatolia. Technically he was subordinate to the Western ruler, Constantius Chlorus. But since Ga-

Galerius, marble bust; in the Capitoline Museum, Rome

Anderson—Mansell from Art Resource

lerius had arranged the appointment of two of his favourites, Maximinus (his nephew) and Flavius Valerius Severus, to be caesars in both East and West, he was in effect the supreme ruler. When Constantius Chlorus died in 306, Galerius insisted that Severus govern the West. Galerius' supremacy was, however, short-lived. Severus was soon overthrown (306) and killed by Maxentius (son of the former emperor Maximian). Galerius invaded Italy but was forced to retreat. In 308 he induced Diocletian and Maximian to meet him at Carnuntum on the Danube and to declare Maxentius a usurper. On November 11, Galerius proclaimed as augustus of the West his friend Licinius, who had effective control only in the region of the Danube.

A ruthless ruler, Galerius imposed the poll tax on the urban population and maintained the persecution of the Christians. In the winter of 310-311, however, he became incapacitated with a painful disease. Fearing, perhaps, that his illness was the vengeance of the Christian God, he issued on April 30, 311, an edict grudgingly granting toleration. Shortly afterward he died. He was succeeded by his nephew Maximinus Daia.

**Galesburg**, city, seat (1873) of Knox county, west-central Illinois, U.S. George Washington Gale, a Presbyterian minister for whom the city was named, selected the site for a college community. In 1836 the first settlers arrived, and in 1837 a charter was granted to the Knox Manual Labour College (renamed Knox College in 1857); in 1930 it absorbed Lombard College, which had been founded by Universalists in 1851. Galesburg's economy is based mainly on agriculture and manufacturing, with coal mining decreasing in importance.

Galesburg was the birthplace of Carl Sandburg, the poet and biographer of Abraham Lincoln. The small house where he lived as a child has been restored. The city's Carl Sandburg (junior) College was opened in 1967, the year of Sandburg's death. Inc. 1857. Pop. (1994 est.) 33,316.

**Galgodon Highlands**, also called **OGO HIGHLANDS**, region of broken mountain terrain, northern Somalia, eastern Africa. It lies parallel to the Gulf of Aden south of the "burnt" Guban coastal plain, and extends from the Ethiopian border in the west to Cape Gardafu (Caseyr) in the east. Rising abruptly from the Guban, the highlands slope gradually to the Hawd plateau in the south and the Nu-gaaleed (Nogal) Valley in the southeast. Near Ceerigaabo (Erigavo) the highlands rise to Somalia's highest point, Surud Cad, which has

an elevation of 7,900 feet (2,408 m). Consisting of old volcanic lava, the region is deeply dissected by a series of shallow, dry riverbeds and narrow, steep valleys. Passes, including the Shiikh and Karinduusha, divide the highlands into separate mountain peaks rising to elevations between 6,000 and 7,900 feet (1,830 and 2,410 m). *Boswellia* and *Commiphora* trees, sources of frankincense and myrrh, respectively, occur in the northeastern part; on higher elevations (above 5,000 feet [1,500 m]) there are some remnants of juniper and cedar forests, now protected by the government. Roads have been cut through the highlands at Shiikh to connect Berbera and Burko and at Tabah to link Maydh and Ceerigaabo.

**Galiani, Ferdinando** (b. Dec. 2, 1728, Chieti, Italy—d. Oct. 30, 1787, Naples), Italian economist whose studies in value theory anticipated much later work.

Galiani served in Paris as secretary to the Neapolitan ambassador (1759–69). Thereafter, he was in government service in Naples, where he helped to formulate and administer economic policy.

Galiani, engraving by Lefevre after a portrait by J. Gillberg

By courtesy of Bildarchiv Preussischer Kulturbesitz BPK Berlin

Galiani wrote in both French and Italian, and his letters are valuable for their depiction of economic, social, and political life in 18th-century Europe. His correspondents included Denis Diderot, Voltaire, and Anne-Robert-Jacques Turgot. He also carried on a spirited intellectual debate with Abbé André Morellet, the spokesman of the Physiocrats.

Galiani published two treatises, *Della moneta* (1750; "On Money") and *Dialogues sur le commerce des blés* (1770; "Dialogues on the Grain Trade"), both of which display clarity of methodological presentation, despite his basic eclecticism. In the first work he evolved a theory of value based on utility and scarcity. In the second he stressed the necessity for the regulation of commerce, opposing the Physiocrats, who advocated complete freedom.

**Gâlib Dede**, also called ŞEYH GÂLIB, pseudonyms of MEHMED ES' AD (b. 1757, Constantinople—d. Jan. 5, 1799, Constantinople), Turkish poet, one of the last great classical poets of Ottoman literature.

Gâlib Dede was born into a family that was well-connected with the Ottoman government and with the Mawlawiyah, or Mevlevîs, an important order of Muslim dervishes. Continuing in the family tradition by becoming an official in the Divan-ı Hümayun, the Ottoman imperial council, he thus established a career for himself in the Ottoman bureaucracy. Later, after giving up this government position, he became the sheikh (superior) of the Galata monastery, in Constantinople, the renowned centre of the Mawlawiyah order. Remaining in this position for the rest of his life, he continued to write poetry. His work was much appreciated by the reigning Ottoman sultan, Selim III (himself a poet, musician, and Mawlawî dervish), and by other

members of the court, who showed him great favour and respect. Gâlib Dede is primarily known for his masterpiece, *Hûsn ü Aşk* ("Beauty and Love"). This allegorical romance describes the courtship of a youth (Hûsn, or "Beauty") and a girl (Aşk, or "Love"). After many tribulations, the couple are finally brought together, allegorizing the fundamental unity of love and beauty. In addition to this famous work, Gâlib Dede is known for his *Divan* (collection of poems). These poems illustrate his preoccupation with mystical religious themes and are characterized by highly symbolic language and complex conceits and wordplay. Thus his work is often inaccessible to the average reader.

**Galicia**, Polish GALICJA, German GALIZIEN, Russian GALYTSIYA, historic region of eastern Europe that was a part of Poland before Austria annexed it in 1772; in the 20th century it was restored to Poland but was later divided between Poland and the Soviet Union.

During the Middle Ages, eastern Galicia, situated between Hungary, Poland, and the western principalities of Kiev and Volhynia, was coveted by its neighbours for its fertile soil and its important commercial connections. Incorporated into Kievan Rus by Vladimir I (Grand Prince Vladimir) in 981, eastern Galicia (also called Red Ruthenia, or Red Rus), being the country around Halicz (Galich, or Galych) on the upper Dniester, east of the Zbruch confluent and west of the headwaters of the San River, became an independent principality in 1087; during the next century it developed into a rich and powerful principality. In 1199 Prince Roman of Volhynia, invited by the Galician boyars (noblemen), ascended the throne in Halicz and united under his power both Volhynia (or Lodomeria) and Galicia in 1200. Under his rule and that of his son Daniel (reigned 1238–64), the united principality defeated both Polish and Hungarian attempts at conquest and asserted itself as a major state in eastern Europe. The principality was weakened, however, by internal struggles between the princes and boyars, who often held the real power in the principality, and, though Daniel was crowned king of Galicia by a papal legate in 1253, he was also compelled to recognize the suzerainty of the Mongol khan, who had conquered the former Kievan territory in 1237–41.

Galicia in the mid-19th century

Galicia, however, did not become an integral part of the Mongol empire as did other lands of Rus, and in 1323, when Roman's dynasty died out, a Polish prince, Boleslaw Jerzy of Mazovia, was elected by the boyars to rule Galicia. After his death (1340), the Polish king Casimir III the Great annexed Galicia to his lands (1349). Under Polish rule Galicia was settled by Polish gentry, who became the dominant social class, and Galician boyars soon were compelled to accept the Polish language as well as Polish legal and social institutions and Roman Catholicism.

When Poland was first partitioned in 1772,

eastern Galicia, together with the territory to the west, between the San and the Vistula, was attached to Austria; and in 1795 further lands, both west and east of the Vistula, passed also to Austria. From 1786 to 1849 Austria administered the territory of Bukovina as part of Galicia. After the adjustments of 1815 (Congress of Vienna), Austria's Polish possessions were called the Kingdom of Galicia and Lodomeria; and the 1815 Republic of Cracow was added to them in 1846. In 1848–49 Austria abolished serfdom in Galicia and after 1867 allowed the region a large degree of administrative autonomy. During the late 19th century, however, the Ukrainian population, which constituted the majority of the inhabitants of eastern Galicia, objected to the increasing domination of the Polish population and developed a strong Ukrainian nationalist movement.

All Galicia became a part of Poland after World War I and postwar controversy. When World War II began, the Soviet Union united eastern Galicia to the Ukrainian Soviet Socialist Republic. Following the war, eastern Galicia remained a part of the U.S.S.R. (after 1991, part of Ukraine), while western, Polish-settled Galicia was attached to Poland.

**Galicia**, *comunidad autónoma* ("autonomous community") and historic region of Spain encompassing the northwestern Spanish *provincias* of Lugo, La Coruña, Pontevedra, and Orense. The *comunidad autónoma* was established by the statute of autonomy in 1981. It is roughly coextensive with the former kingdom of Galicia and borders the Atlantic Ocean on the west and north.

Galicia's name is derived from the Celtic Gallaeci, who lived there when the region was conquered by the Roman legions in about 137 bc. In Roman and Visigothic times Galicia stretched south to the Duero River and eastward to beyond the city of León and formed part of the archdiocese of Bracara Augusta (Braga). From about 410 it was an independent kingdom under the Suebi, who were finally destroyed by the Visigoths in 585. Galicia lost much of its political autonomy after the unification of Castile and Aragon in 1479 and fell under the administration of the royal Junta del Reino de Galicia in 1495.

The cultural revival of Galician as a literary language in the mid-19th century pointed to a growing regional consciousness. The plebiscite of 1936 registered overwhelming support for Galician autonomy but was nullified by the strongly centralized government established by General Francisco Franco.

The modern autonomous community was created in 1981 with a Junta de Galicia (a council headed by a president) and a unicameral assembly. The terrain of Galicia is hilly and relatively uniform in elevation, with more than half its area lying between elevations of 1,300 and 2,000 feet (200 to 600 m) and less than one-fifth at elevations lower than 1,300 feet. Mountains ring the interior, isolating the region from the Spanish *provincias* of Asturias, León, and Zamora to the east and from Portugal to the south. The interior is dominated by strongly dissected mountains, which gradually give way to the coastal plains of the Atlantic and Vizcayan (Bay of Biscay) littorals. Numerous rivers and their affluents drain seaward through Galicia, permitting the region to export hydroelectric power to the rest of Spain. Annual precipitation is moderately high, exceeding 40 inches (1,000 mm) in most places, but it is of only limited benefit, because the badly eroded soil retains little moisture.

Villages are ordinarily small and isolated, the parish being the common denominator among the widely dispersed villages of a locality. The terrain favours animal husbandry over cultivation, and the former is the premier agricultural activity; nonetheless, the farm

population is large and fairly evenly dispersed, resulting in the subdivision of the countryside into small landholdings, or *minifundios*. Families generally own and cultivate the *minifundios*, and the inability of those farms to support a growing population has resulted in a higher than average emigration from Galicia since the 18th century. Overseas emigration was particularly high between 1920 and 1935, while emigration since World War II has been to the industrialized countries of Europe but also to the Spanish *provincias* of Madrid, Vizcaya, and Barcelona. Emigration has been especially high among men, resulting in serious demographic and economic imbalances, among them an aging population and declining economic productivity.

Primary production (agriculture, forestry, and fishing) dominates the region's economy. Subsistence farming prevails among the *minifundios*, with potatoes and corn (maize) among the leading crops and pigs among the leading livestock. Underemployment plagues the agricultural sector, and large numbers of migrant labourers periodically leave Galicia in search of seasonal work elsewhere in Spain. The mountains of the region produce considerable quantities of timber. The port of Vigo is one of Spain's leading fishing ports.

Galicia's industrial sector is not well-developed, and much of it centres on the processing of primary commodities. Fish processing is of particular importance, and sawmills are widespread. The installation of a petroleum refinery (Petroliber) in La Coruña has stimulated industrial development in that province, while El Ferrol del Caudillo and Vigo have major shipbuilding works. Galicia's economy remains underdeveloped, however, accounting for a disproportionately small percentage of Spain's gross domestic product.

Galicia's culture and distinctive dialect have developed in relative isolation, showing greater affinity for Portuguese culture than for that of Spain until the final separation of the two countries in 1668. The literary use of Galician reached its apogee toward the 13th century, when its metre, drawing on that of Provençal, showed greater refinement and versatility than the then relatively underdeveloped Castilian metre. The cultural and political predominance of Castile has since submerged the literary uses of Galician, and most of the region's writers of the 20th century have written in Castilian. The preeminent Galician scholar of the 20th century has been Ramón Menéndez Pidal (1869–1968), whose works centred on Spanish philology and culture. Pop. (1986 est.) 2,870,858.

**Galician dialect**, Portuguese dialect spoken in northwestern Spain, often incorrectly considered a dialect of Spanish. *See* Portuguese language.

**Galician Offensive (World War I):** *see* June Offensive.

**Galilean satellite**, any of the four large satellites of Jupiter discovered by Galileo in 1610 and named by the German astronomer Simon Marius soon afterward. In order of distance from Jupiter, the satellites are Io, Europa, Ganymede, and Callisto. The amount of ice relative to rock in these bodies increases systematically with distance from Jupiter and is thought to reflect a primordial high-luminosity phase of the planet at the time of their formation. The orbits of the inner three satellites are in a resonant state, such that conjunctions of Io and Europa and conjunctions of Europa and Ganymede always occur on opposite sides of Jupiter.

**Galilean telescope**, instrument for viewing distant objects, named after the great Italian scientist Galileo Galilei (1564–1642), who first constructed one in 1609. With it, he discovered Jupiter's four largest satellites, spots on the Sun, phases of Venus, and hills and valleys

on the Moon. It consists of a convergent lens as objective (*i.e.*, the lens that forms the image); and its eyepiece (or ocular), placed in front of the focus, is a divergent lens. An upright image is produced. This simple refracting telescope is still used in modern opera glasses, which are low-powered binoculars.

**Galilean transformations**, also called **NEWTONIAN TRANSFORMATIONS**, set of equations in classical physics that relate the space and time coordinates of two systems moving at a constant velocity relative to each other. Adequate to describe only low-speed phenomena, Galilean transformations formally express the ideas that space and time are absolute; that length, time, and mass are independent of the relative motion of the observer; and that the speed of light depends upon the relative motion of the observer. *Compare* Lorentz transformations.

**Galilee**, Hebrew HA-GALIL, northernmost region of ancient Palestine, corresponding to modern northern Israel. Its biblical boundaries are indistinct; conflicting readings leave clear only that it was part of the territory of the northern tribe of Naphtali.

The frontiers of this hilly area were set down by the Roman-Jewish historian Josephus (1st century AD). They were: Akko (Acre) and Mount Carmel on the west; Samaria and Bet She'an (Scythopolis) on the south; Transjordan on the east; and a line running through ancient Baca (probably modern Bezet) on the north, that line generally corresponding to the modern Israeli-Lebanese boundary. Some geographers extend Galilee's border northward to the Nahr al-Litani (Leontes River).

Galilee is divided into two parts: Upper and Lower. Upper Galilee (chief city: Zefat) has higher peaks separated by narrow gorges and defiles. Lower Galilee (chief city: Nazareth) is a region of lower hills.

When the Israelites took possession of Palestine, the Canaanites were strongly entrenched in Galilee. The Book of Judges (1:30–33) suggests that even after Joshua's conquest, Jews and Canaanites lived together there. During the reigns of David and Solomon (10th century BC), Galilee was part of their expanded kingdom; subsequently, it came under the northern kingdom of Israel.

In 734 BC much of Galilee's Jewish population was exiled after the victory of the Assyrian king Tiglath-pileser III over the Israelite kingdom. Later, the region became known as Jesus' boyhood home and, thereafter, the site of most of his public ministry. Most of the miracles recounted in the New Testament were performed in Galilee. After the destruction of the Second Temple (AD 70) by the Romans, the centre of Jewish scholarship in Palestine moved to Galilee.

Galilee became impoverished after the Arab conquest (636). In the Middle Ages Zefat was the principal centre of Kabbala, an esoteric Jewish mysticism.

The region's revival in modern times is a result of Zionist colonizations. Beginning with the village of Rosh Pinna (Hebrew: "cornerstone") in 1882, a string of settlements was set up; these proved to be key bargaining points in the inclusion of all Galilee in the British mandate (1920).

The United Nations partition plan (November 1947) envisioned the division of Galilee between Israel and the never-created Arab state in Palestine, but it all went to Israel after the 1948–49 Arab-Israeli war.

A major change in Palestine's physical geography was effected in Galilee in the 1950s

when swampy Lake Hula, north of the Sea of Galilee, was drained; the Hula Valley was converted into fertile farmland and the upper course of the Jordan River straightened.

**galilee**, type of porch (*q.v.*) that was developed during the Gothic period.

**Galilee, Sea of**, also called **LAKE TIBERIAS**, Arabic BUHAYRAT ṬABARĪYĀ, Hebrew YAM KINNERET, lake in Israel through which the Jordan River flows. From 1948 to 1967 it was bordered immediately to the northeast by the cease-fire line with Syria. It is famous for its biblical associations. Located 686 feet (209 m) below sea level, it has a surface area of 64 square miles (166 square km). The sea's maximum depth, which occurs in the northeast, is 157 feet (48 m). Measuring 13 miles (21 km) from north to south and 7 miles (11 km) from east to west, it is pear-shaped. Its Old Testament name was Sea of Kinneret (Kinerot), but, after the exile of the Jews to Babylon in the 6th century BC, it was called the Lake of Gennesaret.

Because of a pleasant climate, level topography, fertile soil, and relatively abundant water, the rivers flowing into the lake and the adjacent plains have throughout history been the source of livelihood for various peoples. At El-Ubeidiya, 2 miles (3 km) south of the lake, lacustrine formations dating from about 400,000 to 500,000 years ago have revealed prehistoric tools and two human fragments, which are among the oldest in the Middle East. Canaanite (ancient Palestinian) structures have been uncovered that date back to between 1000 and 2000 BC. In the 1st century AD the region was rich and populated; the Jewish historian Flavius Josephus wrote of nine cities on the shores of the lake in ancient times, but of these only Tiberias has survived. Tiberias, on the western shore, was one of the four Jewish holy cities, and Kefar Nahum (Capernaum), near the northwestern shore, has preserved one of the most beautiful synagogues of the Galilee region, dating from the 2nd and 3rd centuries AD. A sanctuary for the Druze (an independent sect founded in the 11th century that followed a creed containing elements of Islām, Judaism, and Christianity) is located near Kefar Hittim near the western shore. The Sea of Galilee is especially well known to Christians because it was the scene of many episodes in the life of Christ. The region was also the site of the first Jewish kibbutz, Deganya, established in 1909.

The Sea of Galilee is located in the great depression of the Jordan. The Plain of Gennesaret extends in a circular arc from the north to the northwest, and the Plain of Bet Zayda (Buteiha) in Syria extends to the northeast. To the west and the southwest, the hills of Lower Galilee fall abruptly to the lake's edge. In the mid-eastern sections, the cliffs of the Plateau of Golan overlook the lake; the plateau reappears again in the southeast, becoming larger as it approaches the valley of the Yarmuk River, a tributary that has its confluence with the Jordan a few miles to the south of the lake. Also to the south, the Plain of al-Ghawr begins, but the Sea of Galilee is separated from it by a narrow ridge through which the Jordan River flows. The greatest part of the region is covered by basalts that have been formed since the Miocene Epoch began about 26,000,000 years ago and that are part of the vast area of Mount Duruz, located in Syria. Since the Miocene Epoch began, lacustrine limestones and marls (calcareous clays) have been deposited. The rift valley, part of the eastern Africa Rift System, which forms the Jordan Trench, passes to the east of the lake; smaller and less important faults occur to the west. The depression was hollowed out at the end of the Pliocene

Epoch (5.3 to 1.6 million years ago) and was partially filled in again by lacustrine and fluvial sediments. During the humid periods of the Quaternary Period (1.6 million years ago to the present) the Dead Sea extended up to this point. During the last pluvial period, about 20,000 years ago, a great lake, called the Lake of Lisan, covered the region. Since then, the waters have receded.

Because of its sheltered location, low elevation, and the influence of the lake itself, the winters are mild, with temperatures averaging 57° F (14° C) in January. The absence of freezing temperatures has facilitated the cultivation of bananas, dates, citrus fruit, and vegetables. The summers are hot, with temperatures averaging 88° F (31° C), and the precipitation—almost 15 inches (380 mm) at Deganya—falls, in the course of a winter of less than 50 days, in the form of brief but violent showers.

The Sea of Galilee is fed primarily by the Jordan River. Other streams and wadis (seasonal watercourses) flow into the lake from the hills of Galilee. In the rivers associated with the lake and at the bottom of the lake itself are many mineral deposits. Because of these deposits and because of the strong evaporation, the lake's waters are relatively salty.

The lake's fish life has an affinity with that of the eastern African lakes. Fish species to be found include damselfish, scaleless blennies, catfish, mouthbreeders, and barbels.

For the past few centuries the Plains of Gennesaret, to the northwest, and the area around Deganya, to the south, have been systematically developed through irrigation and intensive agricultural techniques. Fishing has also been developed, notably from Tiberias and Gennesaret and at En Gev, on the eastern shore. Significant catches of fish are netted annually from motorboats and trawlers; sardines are mainly caught in winter, though, together with larger fish, they are also caught at other seasons. Thermal springs have enabled modern health resorts to be created, and the baths at Tiberias are among Israel's most important winter resort attractions. Similar baths are to be found at Tabigha, or 'En Sheva' (the seven springs of Bathsheba), on the northwest shore.

In the 1960s the Sea of Galilee became the starting point of the National Water Carrier (also called Kinneret-Negev Conduit), a canal that conveys water from the Jordan River to Israel's densely populated coastal region, as well as south to the Negev Desert. The water is pumped by pipe to the northwest to a height some 800 feet (240 m) above the lake's level, from where it is siphoned across the gorges of Nahal 'Ammud and Zalmon. Another pumping station lifts the water to the height of the Bet Netofa valley and from a reservoir there the water is carried by pipe to irrigate the country's western sector.

**Galilei, Vincenzo** (b. c. 1520, Santa Maria in Monte, near Florence [Italy]—buried July 2, 1591, Florence), father of the astronomer Galileo and a leader of the Florentine Camerata, a group of musical and literary amateurs who sought to revive the monodic (single melody) singing style of ancient Greece.

Galilei studied with the famous Venetian organist, theorist, and composer Giuseffo Zarlino (1517–90) and became a noted luteist and composer. Several books of his madrigals and instrumental music were published in his lifetime, and he is said to have been the first to write solo songs (now lost) in imitation of Greek music as it was then understood.

Galilei engaged in heated attacks on his former teacher Zarlino, particularly on his system of tuning, and published several diatribes against him. Among these is the *Dialogo della musica antica, et della moderna*

(1581; "Dialogue about Ancient and Modern Music"), which contains examples of Greek hymns (among the few known fragments of ancient Greek music). In the same work he attacked the practice of composition in which four or five voices sing different melodic lines simultaneously with different rhythms, thus obscuring the text and ignoring the natural rhythm of the words; this practice was typical of the Italian madrigal style that Galilei came to despise and that went out of fashion in the 17th century.

**Galileo**, in full GALILEO GALILEI (b. Feb. 15, 1564, Pisa [Italy]—d. Jan. 8, 1642, Arcetri, near Florence), Italian mathematician, astronomer, and physicist, considered a founder of the experimental method.

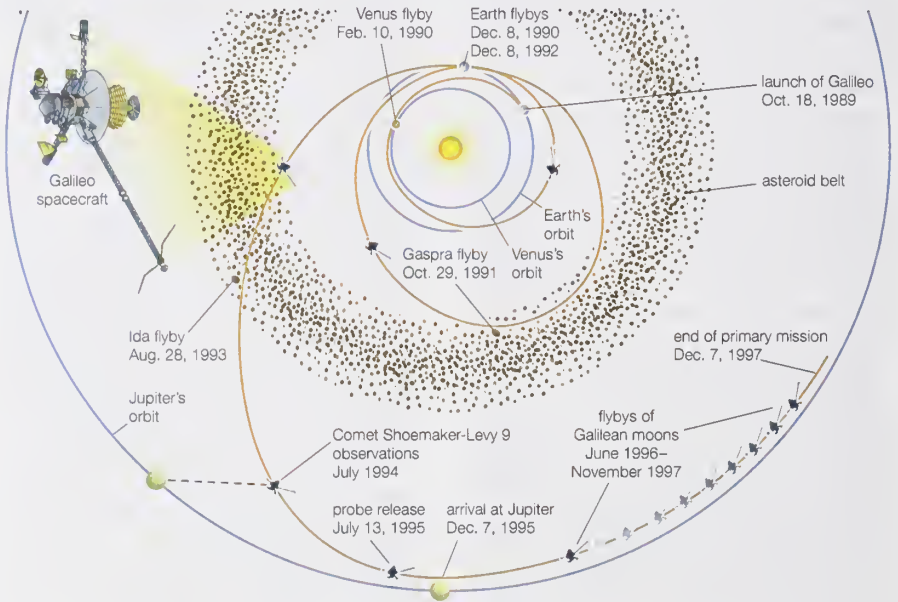

A brief treatment of Galileo follows. For full treatment, see MACROPAEDIA: Galileo.

Galileo—the son of Vincenzo Galilei, a musician—was educated at a monastery near Florence before studying medicine at the Uni-

**Galileo**, in space exploration, robotic U.S. spacecraft launched to Jupiter for extended orbital study of the planet, its magnetic field, and its moons. Galileo was a follow-on to the much briefer flyby visits of Pioneers 10 and 11 (1973–74) and Voyagers 1 and 2 (1979).

Galileo was launched on Oct. 18, 1989, and then boosted into a roundabout trajectory toward Jupiter along which it benefited from a series of gravity-assist, or slingshot, procedures during flybys of Venus and Earth (see diagram). In two passes into the asteroid belt, Galileo flew past the asteroids Gaspra and Ida, providing the first close-up views of such bodies and discovering a tiny moon (Dactyl) orbiting Ida. Galileo also furnished a unique perspective of the collision of Comet Shoemaker-Levy 9 with Jupiter in July 1994.

Prior to orbiting Jupiter on Dec. 7, 1995, Galileo released an atmospheric probe that penetrated the Jovian cloud tops slightly north of the equator. Descending by parachute, the

Journey of the Galileo spacecraft to Jupiter. Galileo's multiple gravity-assist trajectory involved three planetary flybys (Venus once and Earth twice), two passes into the asteroid belt, and a fortuitous view of a comet's collision with Jupiter.

versity of Pisa and mathematics with a private tutor. After completing a treatise on the centre of gravity in solids, he became lecturer in mathematics at the university at the age of 25. Later he went to the University of Padua as a professor of mathematics. The story of his dropping weights from the Leaning Tower of Pisa has no basis in fact.

A substantial part of Galileo's work is related to mechanics, and he was the first to apply mathematics to its analysis. He suggested the use of pendulums for clocks and proposed the law of uniform acceleration for falling bodies. Galileo developed the astronomical telescope, with which he discovered craters on the Moon, sunspots, phases of Venus, and the satellites of Jupiter. He showed that the Milky Way is composed of stars. His astronomical observations led him to espouse the Copernican theory that the planets revolve around the Sun. This conflicted with the teachings of the Roman Catholic church, however, and Galileo was forced to recant his findings and was placed under house arrest for the final eight years of his life for having "held and taught" Copernican doctrine. In 1992 the church formally acknowledged its error in condemning Galileo.

Galileo's major works were *Dialogue Concerning the Two Chief World Systems—Ptolemaic and Copernican* (1632) and *Dialogue Concerning Two New Sciences* (1638).

probe reported on temperature, pressure, density, net energy flows, electrical discharges, cloud structure, and chemical composition for nearly an hour before failing. Over the next five years Galileo flew a series of close encounters with Jupiter's four largest moons—Io, Europa, Ganymede, and Callisto. Despite an inoperative main antenna, Galileo yielded revealing close-up portraits of selected features on the moons and dramatic images of Jupiter's cloud layers, auroras, and storm systems. A highlight was its detailed views of the shattered icy surface of Europa, which showed evidence of a possible subsurface ocean of liquid water. After Galileo completed its two-year primary mission, its orbit was adjusted to make a very close pass of Io and scrutinize its volcanoes in unprecedented detail. In 2002 it was set on a course to destroy itself in Jupiter's atmosphere to prevent its possible contamination of a Jovian moon. (D.M.H.)

**Galiwinku**, formerly ELCHO ISLAND, island in the Arafura Sea, 2 miles (3 km) across Cadell Strait from Napier Peninsula, a part of Northern Territory, Australia, and of the Arnhem Land Aboriginal Reserve. It is low-lying, 30 miles (48 km) long by 7 miles (11 km) wide, and is separated from the Wessel Islands (east) by Brown Strait. The town of Galiwinku, on the southwestern coast, which began as a Methodist mission (established 1947), is administered by an Aboriginal town

council. It is the largest Arnhem Land Aboriginal community, with a population at times as large as 1,400. Rice and other tropical crops are grown. Pop. (1986) town, 1,026.

**Gall** (b. c. 1840, near Moreau River [in present-day South Dakota], U.S.—d. 1894, near Oak Creek, S.D.), Hunkpapa Sioux war chief, who was one of the most important military leaders at the Battle of the Little Bighorn (June 25, 1876).

Orphaned at an early age, Gall was adopted as a younger brother by the Sioux chief Sitting Bull. In many clashes with settlers and the U.S. Army, Gall distinguished himself as an excellent tactician and strategist. At the Battle of the Little Bighorn, Gall is credited with having turned back an initial Indian rout and then luring Lieutenant Colonel George A. Custer and his men into an indefensible position, annihilating his force. After this victory, Gall and Sitting Bull faced continual skirmishes and battles with the military, and in May 1877 he followed Sitting Bull into Canada. The Canadian government would not give them a reservation, the herds of buffalo were gone, and Gall and his people faced starvation. He eventually abandoned Sitting Bull and surrendered to the U.S. Army (c. 1880). Once on the Sioux reservation in South Dakota, Gall urged his people to become more acculturated with the whites. His breach with Sitting Bull (who eventually lived on the reservation) became complete when Gall was persuaded to sign the treaty of 1889 that broke up the so-called Great Sioux Reservation and ceded much territory to white settlers.

**gall** (digestion): *see* bile.

**gall**, an abnormal, localized outgrowth or swelling of plant tissue caused by infection

Galls of cynipid wasp *Antron douglasii* on oak leaves

from bacteria, fungi, viruses, and nematodes or irritation by insects and mites. *See* black knot; cedar-apple rust; clubroot; crown gall.

**Gall, SAINT** (b. c. 550, Ireland—d. c. 645, Switzerland; feast day October 16), Irish monk who helped spread Irish influence while introducing Christianity to western Europe.

Educated at the monastery of Bangor (in present-day North Down district, N.Ire.), Gall became a disciple of St. Columban and joined him on a mission to France. When Columban proceeded to Italy, Gall remained with the semipagan Alemanni, a Germanic people living in Gaul and northern Switzerland. In 612 he founded a hermitage on the site of modern Sankt Gallen, Switz. The Abbey of St. Gall was founded about 720 on the site of Gall's hermitage. The earliest biographical account of Gall, of which only a fragment survives, dates from the 8th century.

**Gall, Franz Joseph** (b. March 9, 1758, Tiefenbronn, Baden [Germany]—d. Aug. 22, 1828, Paris, Fr.), German anatomist and physiologist, a pioneer in ascribing cerebral functions to various areas of the brain (localization). He originated phrenology, the attempt to divine individual intellect and personality from an examination of skull shape.

Convinced that mental functions are localized in specific regions of the brain and that human behaviour is dependent upon these functions, Gall assumed that the surface of the skull faithfully reflects the relative development of the various regions of the brain. His popular lectures in Vienna on "cranioscopy" (called phrenology by his followers) offended religious leaders, were condemned in 1802 by the Austrian government as contrary to religion, and were banned. Three years later he was forced to leave the country.

His concept of localized functions in the brain was proved correct when the French

Franz Joseph Gall, engraving by Friedrich Wilhelm Bollinger after a portrait by Karl Heinrich Rahl, c. 1812  
Archiv für Kunst und Geschichte, Berlin

surgeon Paul Broca demonstrated the existence of a speech centre in the brain (1861). It was also shown, however, that, since skull thickness varies, the surface of the skull does not reflect the topography of the brain, invalidating the basic premise of phrenology. Gall was the first to identify the gray matter of the brain with active tissue (neurons) and the white matter with conducting tissue (ganglia).

**gall midge** (family Cecidomyiidae, or Itonididae), any minute, delicate insect (order Diptera) characterized by beaded, somewhat hairy antennae and few veins in the short-haired wings. The brightly coloured larvae live in leaves and flowers, usually causing the formation of tissue swellings (galls). A few live in galls produced by other dipters. Pupation takes place in the gall or in the soil; the winter is passed in an immature stage.

The Hessian fly (*q.v.*) is the most serious pest within the family. In Europe and North America the chrysanthemum midge (*Diarthronomyia hypogaea*) makes small galls in the leaves. The rose midge (*Dasyneura rhodophaga*) infests the young buds and shoots of roses and is a serious pest in greenhouses but rarely outside. Some other serious pests are the wheat midge, sorghum midge, rice midge, clover midge, and pear midge. Tobacco fumigation and dust on soil are used to control these insects.

A few beneficial species of gall midges prey on aphids, mites, scale insects, and bark beetle larvae. An interesting species of the genus *Miastor* exhibits an unusual method of reproduction called paedogenesis: large larvae produce smaller daughter larvae that remain inside the mother larva, feeding on it and eventually consuming it. The daughter larvae then escape and may reproduce in a similar manner for several generations before pupation takes place.

**gall wasp** (subfamily Cynipinae), any of a group of insects (family Cynipidae, order Hymenoptera), notable for their ability to stimulate the growth of galls (tissue swellings) on plants. Some gall wasp species are gall inquilines; *i.e.*, they do not cause the formation of galls but inhabit those made by other insects. The overgrowth of tissue, or gall, presumably is caused by a substance secreted by the immature insect living within it.

Most of the approximately 600 species of gall wasps that occur in North America are about 6 to 8 mm (about 0.25 to 0.30 inch) long and black. The shiny abdomen is oval, and the thorax has a sculptured appearance.

A given species of gall wasp will cause a characteristic type of gall to form on a certain part of a particular species of plant; many of the wasps attack oak trees or rose plants.

Male gall wasps are rare. Reproduction is usually by parthenogenesis; *i.e.*, larvae develop from unfertilized eggs. The egg passes through the long ovipositor of the female and into the plant tissue. After the egg hatches into a larva, the plant tissues around it begin to grow faster than normal. The gall grows with the larva, which feeds on the plant tissue and pupates into an adult within the gall.

The so-called oak apple, a round, spongy, fruitlike object about 2.5 to 5 cm (1 to 2 inches) in diameter, is caused by the larvae of the gall wasp *Biorhiza pallida*. About 30 such larvae may develop in a single "apple," or gall. The marble gall, a green or brown growth about 2.5 cm in diameter, is caused by *Andricus kollari*. The becdugar gall (also called moss gall, or robin's pincushion) is commonly seen on rose bushes and is caused by the gall wasp *Diptolepis rosae*.

Most gall wasps are not economically important. The galls of some species, however, have been used as a source of tannic acid or in the manufacture of inks or dyes.

**Gallagher, Ed; and Shean, Al**, bynames of EDWARD GALLAGHER and ALBERT SHEAN, Shean's original name ALBERT SCHOENBERG, or SCHONBERG (respectively b. 1863?, San Francisco, Calif., U.S.—d. May 28, 1929, Astoria, New York, N.Y.; b. May 12, 1868, Dornum?, near Hannover, Prussia [Germany]—d. Aug. 12, 1949, New York, N.Y.), celebrated American vaudeville team featured in the *Ziegfeld Follies* and other Broadway revues.

(Left) Gallagher and (right) Shean

By courtesy of the Theatre Collection, The New York Public Library at Lincoln Center, Astor, Lenox and Tilden Foundations

Both men began separate careers as comedy and variety troupers in small-time burlesque and vaudeville before joining in 1910 to form the act of "Gallagher and Shean." They went separate ways from 1914 to 1920, but in the latter year (at the urging of Shean's sister Minnie Marx, mother of the Marx Brothers) they rejoined to star in the Shubert Brothers' *Cinderella on Broadway*, with huge success. They then appeared in the *Ziegfeld Follies* of 1922, in which they sang their famous patter song, "Absolutely, Mr. Gallagher? Positively, Mr. Shean!" (Shean wrote the music, and Brian Foy the lyrics). Their popularity in this show and others was immense and inspired a host of imitators. Their success was short-lived, however. Gallagher became involved in a series of litigations—with Foy over song rights, with the Shuberts, with his third wife

in a divorce suit, and with Shean. The team folded in 1925, and Gallagher suffered a nervous breakdown from which he never fully recovered; he died in a sanitarium four years later.

Shean continued in vaudeville and eventually moved into straight dramatic and comedic roles as a character actor on both stage and screen, appearing in 25 Hollywood films from 1934 to 1944.

**Galland, Adolf**, in full ADOLF JOSEPH FERDINAND GALLAND (b. March 19, 1912, Westerholt, near Recklinghausen, Ger.—d. Feb. 9, 1996, Oberwinter), German fighter ace and officer who commanded the fighter forces of the Luftwaffe (German air force) during World War II.

The son of an estate bailiff of French descent, Galland became a skillful glider pilot before age 20 and joined the civilian airline Lufthansa in 1932. He served with Germany's Condor Legion in the Spanish Civil War in 1937–38, flying several hundred missions. Galland held a staff post when Germany invaded Poland in 1939, but he went on to serve in a fighter group during the campaign against France in 1940 and led a fighter squadron during the Battle of Britain, by the end of which he had destroyed about 100 enemy planes. In November 1941 he was promoted to the post of commander of the Luftwaffe's Fighter Arm, and a year later he was promoted to major general, becoming at age 30 the youngest general in the German armed forces.

In 1943–44 Galland commanded Germany's fighter squadrons in their unavailing defense against Anglo-American bombing raids. Despite his able and resourceful leadership, he was blamed by Adolf Hitler and Hermann Göring for the gradual collapse of the German air defenses in 1944, and he was relieved of his command in January 1945. He was soon returned to active duty as the commander of an elite squadron of jet fighters. At the war's end he was captured and imprisoned for a time. He later served as a technical adviser to the Argentine air force for six years, after which he returned to West Germany and worked as an aviation consultant in Düsseldorf.

**Galland, Antoine** (b. 1646, Rollot, near Montdidier, France—d. 1715, Paris), French Orientalist and scholar, best known for his adaptation of the Middle Eastern tales *Les Mille et une nuits* (1704–17; *The Thousand and One Nights*).

Antoine Galland, engraving by Morel after a portrait by Hyacinthe Rigaud  
J.P. Ziolo

The seventh child of a poor family, Galland was taught Hebrew, Latin, and Greek by canons and attended the College of Noyon and the Collège de France in Paris. He accompanied the French ambassador to Constantinople during 1670–75, learned Arabic, Persian, and Turkish, and wrote a journal of his travels.

In 1679 he was appointed antiquary to Louis XIV, for whom he collected ancient coins and manuscripts. In addition to his work on dictionaries and academic writings, he translated the Qur'an and in 1694 wrote *Les Paroles remarquables, les bons mots et les maximes des Orientaux* (*The Remarkable Sayings, Apothegms, and Maxims of the Eastern Nations*), a compendium of Eastern wisdom, and *Les Contes et fables indiennes de Bidpai et de Lokmam* (1724; "Indian Fables and Tales of Bidpai and Lokmam"). His major work, *Les Mille et une nuits*, was a popular version freely translated from Syrian manuscripts.

**Gallas, Matthias, Count (Graf) von Campo, Duke (Herzog) von Lucera** (b. Sept. 16, 1584, Trento [Italy]—d. April 25, 1647, Vienna, Austria), imperial general whose ineffectiveness severely damaged the Habsburg cause in the latter stages of the Thirty Years' War.

Gallas, detail from an engraving  
By courtesy of the Heeresgeschichtliches Museum, Vienna

Albrecht von Wallenstein, impressed by Gallas' military exploits in battles of the middle and late 1620s, entrusted him with important commands (1631–33) against Gustav II Adolf of Sweden and Bernhard of Saxe-Weimar; but Gallas, together with Ottavio Piccolomini, was instrumental in the overthrow of Wallenstein, after whose murder (1634) he obtained the supreme command of the army. Although Gallas was victor in the first of the battles of Nördlingen in 1634, carelessness and drunkenness thereafter marred his conduct of the war, and he became known as the "destroyer of armies," especially after his disastrous campaigns of 1637, 1638, and 1644, each of which resulted in the annihilation of his troops. Eventually he was forced to resign his command.

**Gallatin, Albert**, in full ABRAHAM ALFONSE ALBERT GALLATIN (b. Jan. 29, 1761, Geneva, Switz.—d. Aug. 12, 1849, Astoria, N.Y., U.S.), fourth U.S. secretary of the Treasury (1801–14). He insisted upon a continuity of sound governmental fiscal policies when the Republican (Jeffersonian) Party assumed national political power, and he was instrumental in negotiating an end to the War of 1812.

Gallatin, portrait by Rembrandt Peale, 1805; in Independence National Historical Park, Philadelphia  
By courtesy of the Independence National Historical Park Collection, Philadelphia

Gallatin plunged into business and public life after emigrating to the New World at age 19. Settling in Pennsylvania, he became a mainstay of the anti-Federalists in that area and in 1795 was elected to the House of Representatives. There he inaugurated the House Committee on Finance, which later grew into the powerful Ways and Means Committee. In 1797–98 he helped to reduce Federalist-sponsored expenditures aimed at promoting hostilities with France. He was bitterly denounced by Federalists in Congress, and, when the Alien and Sedition Acts were passed in 1798, Thomas Jefferson believed they were partly intended to drive Gallatin from office.

As secretary of the Treasury Gallatin stressed simplicity in government and termination of the public debt. Despite heavy naval expenditures and the \$15,000,000 Louisiana Purchase (1803), he managed to reduce the public debt by \$23,000,000 within eight years.

The declaration of war with Great Britain in 1812 shattered all of Gallatin's most cherished schemes, for he felt war to be fatal to the nation's prosperity and progress. He therefore put the nation's finances in the best order he could and set himself to attain an early peace. Grasping at Russia's proffered mediation of the war, he sailed for Europe in May 1813. Refusing to deal through Russia, Great Britain expressed its willingness to proceed with direct negotiations, and commissioners from the two countries finally met at Ghent in August 1814. In the tedious discussions that followed, Gallatin played the leading role, preserving peace among his colleagues and establishing an enviable reputation as a diplomat. Peace was signed in the Treaty of Ghent (December 24).

While still in Europe, Gallatin was appointed minister to France (served 1816–23), after which he returned to the United States, only to be embroiled in a bitter intraparty political struggle. Though nominated for the vice presidency in 1824, he withdrew in October to avoid weakening the ticket because of his foreign birth. After serving briefly as minister to Great Britain (1826–27), he retired from public life and became president of the National (later the Gallatin) Bank in New York City (1831–39). A student of the Indian tribes in North America, he founded the American Ethnological Society of New York (1842) and has sometimes been called the "father of American ethnology."

**Gallatin River**, river rising in the Gallatin Range in the northwestern corner of Yellowstone National Park, Wyoming, U.S., and flowing 120 miles (193 km) north to Three Forks, in southwestern Montana. There it joins with its tributary, the East Gallatin (which rises near Mount Blackmore), and the Madison and Jefferson rivers to form the Missouri River. Named for Albert Gallatin, the early 19th-century statesman, it forms a deep canyon about 70 miles (110 km) long between the Madison and Gallatin ranges. The river is used for irrigation.

**Gallaudet, Thomas Hopkins** (b. Dec. 10, 1787, Philadelphia, Pa., U.S.—d. Sept. 10, 1851, Hartford, Conn.), educational philanthropist and founder of the first American school for the deaf.

After graduation from Yale College in 1805, Gallaudet studied theology at Andover. His interests soon turned to the education of the deaf, and he visited Europe, studying in England and France, where he learned the sign method of communication from Abbé Roch-Ambroise Sicard. On his return to the United States in 1816, he established the American Asylum for Deaf-mutes at Hartford, in support of which the U.S. Congress made a land grant. For over 50 years this school was the main training centre for instructors of the deaf.

After retiring from the school in 1830, Galaudet was appointed to the first professorship in the United States for the philosophy of education at New York University (1832–33). In his *Plan of a Seminary for the Education of Instructors of Youth* (1825), he proposed special schools for the professional training of teachers. He also wrote textbooks for children and the deaf.

**gallbladder**, a muscular membranous sac occurring in many vertebrates; its function is to store and concentrate bile, a fluid that is received from the liver and is important in digestion. Situated in humans on the underside of the liver, the gallbladder is pear-shaped and expandable, with a capacity of about 1.7 fluid ounces (50 ml). The inner surface of the gallbladder wall is lined with mucous membrane tissue similar to that of the small intestine. Cells of the mucous membrane perform the function of absorption; each cell's surface has hundreds of microscopic projections called microvilli, which increase the area of fluid absorption. The absorption of water and inorganic salts from the bile by the mucous-membrane cells leaves the stored bile about 5 times—and sometimes as much as 18 times—more concentrated than when it was produced in the liver.

Contraction of the muscle wall in the gallbladder is stimulated by the vagus nerve of the parasympathetic system and by the hormone cholecystokinin, which is produced in the upper portions of the intestine. The gallbladder's contraction results in the discharge of bile through the bile duct into the duodenum of the small intestine. The human bile duct is composed of three branches (hepatic duct, cystic duct, and common duct), which are arranged into the shape of the letter Y. The lower segment is the common bile duct; it terminates in the duodenal wall of the small intestine. A constriction at the end of the common duct, called the sphincter of Oddi (for Ruggero Oddi, a 19th-century Italian physician), regulates the flow of bile into the duodenum. The upper right branch is the hepatic duct, which leads to the liver, where bile is produced. The upper left branch, the cystic duct, passes to the gallbladder, where bile is stored.

Bile flows from the two lobes of the liver into the hepatic and common ducts. If food is present in the small intestine, the bile will continue directly into the duodenum. If the small intestine is empty, the sphincter of Oddi is closed, and bile flowing down the common duct accumulates and is forced back up the tube until it reaches the open cystic duct. It flows into the cystic duct and gallbladder, where it is stored and concentrated until needed. When food enters the duodenum, the common duct's sphincter opens, the gallbladder contracts, and bile enters the duodenum to aid in the digestion of fats.

In animals without a gallbladder, such as horses, rats, and pigeons, bile comes directly from the liver. Some animals have a gallbladder that does not concentrate fluids well; these animals usually have a continuous flow of bile into the intestine.

The gallbladder is commonly subject to many disorders, particularly the formation of solid deposits called gallstones. Despite its activity, it can be surgically removed without serious effect. *See also* bile.

**Galle**, formerly **POINT DE GALLE**, port and city, Sri Lanka (Ceylon), situated on a large harbour on the island's southern coast. Galle dates from the 13th century, possibly much earlier, but it became the island's chief port during the period of Portuguese rule (1507–c. 1640). Under Dutch rule it was the island capital until 1656, when Colombo replaced it. The rise of Colombo's port in the second half of the 19th century led to Galle's decline, but congestion at Colombo has caused some ship-

Ramparts of an old Dutch fort, Galle, Sri Lanka  
Harrison Forman

ping to be diverted to Galle. The city, 65 miles (105 km) southeast of Colombo, has good road and rail connections; a cement factory is in operation there. A fort and other buildings remain from the early colonial period. Pop. (1983 est.) 88,000.

**Gallé, Émile** (b. May 8, 1846, Nancy, Fr.—d. Sept. 23, 1904, Nancy), celebrated French designer and pioneer in technical innovations in glass. He was a leading initiator of the Art Nouveau style and of the modern renaissance of French art glass.

The son of a successful faience and furniture producer, Gallé studied philosophy, botany, and drawing, later learning glassmaking at Meisenthal, Fr. After the Franco-German War

Vase with relief decoration by Émile Gallé, c. 1895; in the Victoria and Albert Museum, London

By courtesy of the Victoria and Albert Museum, London

(1870–71), he went to work in his father's factory at Nancy. He first made clear glass, lightly tinted and decorated with enamel and engraving, but he soon developed the use of deeply coloured, almost opaque glasses in heavy masses, often layered in several thicknesses and carved or etched to form plant motifs. His glass was a great success at the Paris Exhibition of 1878, and he became known as a spirited designer working in contemporary revival styles.

Gallé's strikingly original work made a great impression when it was exhibited at the Paris Exposition of 1889. Over the next decade his glass, reflecting the prevailing interest in Japanese art, became internationally known and imitated. It contributed largely to the free, asymmetric naturalism and symbolistic overtones of Art Nouveau. He employed wheel cutting, acid etching, casing (*i.e.*, layers of various glass), and special effects such as metallic foils and air bubbles, calling his experiments *marqueterie de verre* ("marquetry of glass"). At Nancy he led the revival of craftsmanship and the subsequent dissemination of crafted glass

by way of mass production. At the height of its productivity, during the late 19th century, his workshop employed nearly 300 associates. He attracted numerous artisans, including the Art Nouveau glassmaker Eugène Rousseau. After Gallé's death his glass enterprise continued production until 1913.

With Gallé as its creative force, a form of naturalism, predominantly floristic, developed that was later identified with The School at Nancy, Provincial Alliance of Art Industries, established in 1901. His study of botany was the source for his natural designs, which represented leaves, ethereal flowers, vines, and fruits. His furniture designs, based on the Rococo period, continued the French tradition of emphasizing constructive points organically (*e.g.*, corners of armoires finished in the shape of stalks or tree branches) and employing inlay and carving that were essentially floral in style. Perhaps his most characteristic concept was his *meubles parlants* ("talking furniture"), which incorporated in its decoration inlaid quotations from leading contemporary Symbolist authors such as Maurice Maeterlinck and Paul Verlaine. Both his glass and furniture were signed, sometimes most imaginatively. He collaborated with many colleagues, most notably the Art Nouveau furniture designer Louis Majorelle.

L. de Fourcaud's *Émile Gallé* (1903) preceded Gallé's own book *Écrits pour l'art 1884–89* ("Writings on Art 1884–89"), which was posthumously published in 1908.

**Galle, Johann Gottfried** (b. June 9, 1812, near Gräfenhainichen, Prussian Saxony—d. July 10, 1910, Potsdam, Ger.), German astronomer who on Sept. 23, 1846, was the first to observe the planet Neptune.

Galle joined the staff of the Berlin Observatory, where he served as assistant director under J.F. Encke from 1835 until 1851. He studied the rings of Saturn and suggested a method, later successful, of measuring the scale of the solar system by observing the parallax of asteroids. He looked for Neptune at the request of the French astronomer U.-J.-J. Le Verrier, who had computed the planet's probable position before it was seen. From 1851 until 1897 Galle was director of the Breslau Observatory.

**Gallegos (Freire), Rómulo** (b. Aug. 2, 1884, Caracas—d. April 4, 1969, Caracas), novelist and president of Venezuela in 1948, best known for his forceful novels that dramatize the overpowering natural aspects of the Venezuelan llanos (prairies), the local folklore, and such social events as alligator hunts.

Gallegos

By courtesy of the Organization of American States

Gallegos won an international reputation as one of the leading novelists of South America with *Doña Bárbara* (1929; Eng. trans., 1931), the story of the ruthless woman boss of a hacienda who is more than a match for the criminals, desperadoes, and opportunists who exploit the raw country. Other major

novels are: *Cantaclaro* (1934; "Chanticleer"), dealing with a ballad singer of the llanos, and *Canaïma* (1935), a story of the tropical forest, named after the evil spirit that pervades the jungle.

Other important works were *Pobre negro* (1937; "Poor Black"), *El forastero* (1942; "The Stranger"), *Sobre la misma tierra* (1943; "Over the Same Ground"), *La rebelión y otros cuentos* (1947; "The Rebellion and Other Stories"), and *La brizna de paja en el viento* (1952; "A Straw in the Wind"). He also wrote several screenplays.

In 1936 Gallegos began a political career that eventually led to his inauguration to the presidency of Venezuela in February 1948. His government was overthrown by a military coup in November 1948, however, and he was sent into exile, but he subsequently returned in 1958 and was voted life membership in the Senate.

**Gallehus Horns**, pair of gold, horn-shaped artifacts from 5th-century Scandinavia that constituted the most notable examples of gold-work of that period. They were unearthed at Gallehus, Jutland, Den., in 1639 and 1734 and were stolen and melted down in 1802. Replicas made from drawings are now in the Danish National Museum, Copenhagen. The larger horn, which measured more than 2.5 feet (0.75 m) long, bore the runic inscription "I Hlewegast [or Laegaest], Holt's son, made the horn." The engraved pictures and symbols (which include animals, hunters, and a three-headed figure), arranged in bands running around the sections of the horns, probably had religious significance.

**galleon**, full-rigged sailing ship that was built primarily for war, and which developed in the 15th and 16th centuries. The name derived from "galley," which had come to be synonymous with "war vessel" and whose characteristic beaked prow the new ship retained. A high, square forecastle rose behind the bow, the three or four masts carried both square and fore-and-aft sails, and one or two tiers of guns were carried broadside. The largest galleons were built by the Spanish and the Portuguese for their profitable overseas trade; the famed "Manila galleons" of Spain made an annual trip between Acapulco, Mex., and the Philippines, carrying silver west and raw silk east, for more than 250 years.

**gallery**, in architecture, any covered passage that is open at one side, such as a portico or a colonnade. More specifically, in late medieval and Renaissance Italian architecture, it is a narrow balcony or platform running the length of a wall. In Romanesque architecture, especially in Italy and Germany, an arcaded wall-passage on the outside of a structure is known as a dwarf gallery.

Facing into a structure, a gallery may either be set into the thickness of a wall at ground level or be elevated and supported on columns or corbels. It would function as a communicating passage. Within an interior space a gallery may be a platform projecting from a wall, as in the example of a musicians' gallery, or may be a second-story opening onto a large interior area, such as the gallery in a church intended to provide additional seating. In legislative houses such a gallery might be intended for spectators or the press. In theatres the gallery is the highest balcony and generally contains the least expensive seats.

Galleries appear as long, narrow rooms in substantial Renaissance houses and palaces, where they were used as promenades and to exhibit art. In Elizabethan and Jacobean houses these were called long galleries. The modern term art gallery is derived from this usage.

**gallery grave**, long chamber grave, a variant of the collective tomb burials that spread into western and northwestern Europe from the Aegean area during the final stage of the northern Stone Age (c. 2000 BC). In the Severn-Cotswold area of Britain, the gallery graves have pairs of side chambers. Segmented graves with concave forecourts are found in Ulster and southwestern Scotland. In the Paris Basin, the gallery graves have small round entrances and are lined with large stone slabs. The tombs are often associated with deities, whose representations are depicted on the rock walls.

**galley**, large seagoing vessel propelled primarily by oars. The Egyptians, Cretans, and other ancient peoples used sail-equipped galleys for both war and commerce. The Phoenicians were apparently the first to introduce the bireme (about 700 BC), which had two banks of oars staggered on either side of the vessel, with the upper bank situated above the lower so as to permit the oars of the upper bank to clear the oars below. The addition of an outrigger permitted the employment of a third bank of oars, the rowers of which sat

above and outside the other two; such a ship, which was called a trireme, was probably first constructed about 500 BC by the Greeks. References to even more banks (for example, the quinquireme) are believed to indicate a ship of very large size but with no more than two or three banks of oars.

A distinctive body of naval tactics based on the use of war galleys developed in the Mediterranean Sea from the 5th century BC on. In imitation of contemporary land warfare, the galleys cruised in columns, generally several abreast. Upon engaging the enemy they assumed a phalanxlike formation in lines abreast. In this manner each galley could give protection to its neighbours' exposed sides. At the same time it could confront the enemy with its bow, which was equipped with a ram, grappling irons, and missile-hurling devices.

By late Roman times, war galleys had become sharply differentiated from merchantmen by their longer, narrower hulls and prow

Galley of the largest size, with five men on each oar, early 17th century

By courtesy of the trustees of the British Museum

rams. The wider, deeper hulled merchantmen relied increasingly on the sail, and ultimately all-sail vessels came into use. Galleys, however, were not entirely replaced for commerce even in late medieval times. More expensive (because of the larger crews) but more maneuverable, the galley remained the principal ship for peace and war into the High Middle Ages. The Vikings' longships were small galleys with up to 10 oars on a side and a square sail and were capable of carrying 50 or 60 men. Byzantium, Venice, Genoa, and other medieval sea powers built much more elaborate galleys; by the 13th century Italian galleys were trading in Flanders and England and on the northwest coast of Africa. In 1291 two Genoese galleys were lost seeking a sea route to the Indies via the West African coast.

Though the advent of the lateen (fore-and-aft) sail and the stern rudder rendered the galley obsolete for commerce, it retained its military importance into the 16th century. It played the leading role at the Battle of Lepanto in 1571.

The galley's last historic role was as a convict ship, to which felons were sentenced in France and elsewhere into the 18th century. Earlier, prisoners of war had sometimes been used to man galleys, even though free citizens, who could be relied on in battle, were understandably preferred.

**galli**, singular GALLUS, priests, often temple attendants or wandering mendicants, of the ancient Asiatic deity, the Great Mother of the Gods, known as Cybele, or Agdistis, in Greek and Latin literature. The *galli* were eunuchs attired in female garb, with long hair fragrant with ointment. Together with priestesses, they celebrated the Great Mother's rites with wild music and dancing until their frenzied excitement found its culmination in self-scourging, self-laceration, or exhaustion. Self-emasculation by candidates for the priesthood sometimes accompanied this delirium of worship.

The name *galli* may be Phrygian, from the two streams called Gallus, both tributaries of the Sangarius (now Sakarya) River, the waters of which were said to inspire religious frenzy.

**Galli DA BIBIENA FAMILY:** see Bibiena family.

**Galli-Curci, Amelita** (b. Nov. 18, 1882, Milan—d. Nov. 26, 1963, La Jolla, Calif., U.S.), one of the outstanding operatic sopranos of her time, famed for the beauty of her florid coloratura singing.

Galli-Curci studied piano and composition at Milan, but as a singer she was self-taught. After her debut as Gilda in Verdi's *Rigoletto* at Trani, in southern Italy, she appeared in Rome in 1909 in Bizet's *Don Procopio*. Tours with opera companies in Egypt, South America, Spain, and Russia established local reputations for her. She was almost unknown in the United States in 1916 when she appeared in Chicago as Gilda. She appeared in New York City in 1918 as Meyerbeer's Dinorah, a role that became one of her most celebrated. From 1921 until 1930 she sang with the Metropolitan Opera Company. Foreign concert tours followed, and in 1936 she made her final stage appearance in Puccini's *La Bohème*. Her voice was exceptionally fluent, warm, and smooth; her specialty was florid, high soprano music. Her repertory included 28 operatic roles ranging from Rossini's Rosina (in *The Barber of*

**galliard** (French *gaillard*: "lively"), vigorous 16th-century European court dance. Its four hopping steps and one high leap permitted

**Gallia Belgica** (Roman province): see Belgica.

**Gallia Cisalpina:** see Cisalpine Gaul.

**Gallia Comata** (Latin: Hairy Gaul), also called *TRES GALLIAE* (Three Gauls), in Roman antiquity, the land of Gaul that included the three provinces of (1) Aquitania, bordered by the Bay of Biscay on the west and the Pyrenees on the south; (2) Celtica (or Gallia Lugdunensis), with Lugdunum (Lyon) as its capital, on the eastern border of Gaul; and (3) Belgica (or Gallia Belgica), in the north, where Trier and Reims were the chief towns and many of the people were Germanic in origin. The only garrison was a single cohort at Lugdunum to guard the imperial mint, but the Rhine army could and did move rapidly into the Gallia Comata if trouble occurred.

A fourth Roman province, Narbonensis, lay between them and the Mediterranean. It was governed by a proconsul appointed by the Senate, whereas each of the Tres Galliae was ruled by an imperial legate of praetorian standing.

**Gallia Lugdunensis** (Roman province): see Lugdunensis.

**Gallia Narbonensis** (ancient Gaul): see Narbonensis.

**Gallia Transalpina:** see Transalpine Gaul.

athletic gentlemen to show off for their partners. Performed as the afterdance of the stately pavane, the galliard originated in 15th-century Italy. It was especially fashionable from c. 1530 to 1620 in France, Spain, and England, where it was often called the cinqupace after its five basic steps (French *cinqupas*). Queen Elizabeth I is said to have practiced galliards as her morning exercise.

To perform the galliard, couples danced the length of the ballroom either together, men leaping higher than women, or separately. In the wooing pantomime of the early galliard, the men pursued their coyly retreating partners. The step was performed in six counts (two measures of music in moderate  $\frac{3}{4}$  time). Musicians usually wrote pavaens and galliards in pairs, the galliard time being a rhythmic adaptation of that of the preceding pavane.

**gallic acid**, substance occurring in many plants, either in the free state or combined as gallotannin. It is present to the extent of 40–60 percent combined as gallotannic acid in tara (any of various plants of the genus *Caesalpinia*) and in Aleppo and Chinese galls (swellings of plant tissue), from which it is obtained commercially by the action of acids or alkalis. An Aleppo gall has a spherical shape, is hard and brittle, and is about the size of a hickory nut; it is produced on oak twigs by a gall wasp (*Cynips tinctoria*). A Chinese gall is produced by insects on Asian sumac (*Rhus semialata*).

When heated to 200°–250° C, gallic acid splits into carbon dioxide and pyrogallol (pyrogallol), the photographic developer. With iron salts it gives a deep blue-black colour, the basis of writing ink. It is used in the manufacture of a few dyes. As bismuth subgallate it has been employed in medicine as a mild skin antiseptic and astringent (*q.v.*; an agent that tends to shrink mucous membranes and raw surfaces and to dry up secretions). Propyl gallate is an important antioxidant for the prevention of rancidity in edible oils and fats. Gallic acid is 3,4,5-trihydroxybenzoic acid and has the formula  $(HO)_3C_6H_2 \cdot CO_2H$ .

**Gallic Wars** (58–50 BC), campaigns in which the Roman proconsul Julius Caesar conquered Gaul. Clad in the bloodred cloak he usually wore "as his distinguishing mark of battle,"

Caesar led his troops to victories throughout the province, his major triumph being the defeat of the Gallic army led by the chieftain Vercingetorix, in 52 BC. Caesar described these campaigns in *De Bello Gallico* ("On the Gallic War").

**Gallican chant**, music of the ancient Latin Roman Catholic liturgy in the Gaul of the Franks from about the 5th to the 9th century. Scholars assume that a simple and uniform liturgy existed in western Europe until the end of the 5th century and that only in the 6th century did the Gallican church develop its own rite and chant with Oriental influences.

Because of the desire of Rome to have a unified liturgical practice in the West, the Frankish kings Pepin III (d. 768) and Charlemagne (d. 814) suppressed the Gallican rite in favour of the Roman. Although no known manuscripts of Gallican chant have survived, some authentic remnants of it are found in the repertory of Gregorian chant in the liturgy for Good Friday, among them the "Improperia," "Crux fidelis," and "Pange lingua." These chants embedded in the Roman liturgy help to illustrate the theory that the Gregorian chant that has come down to modern times is a synthesis of Roman and Frankish elements. Certain characteristics stand out from surviving examples of Gallican chant. There is a pull in the chants toward cadences on C; motifs are frequently built on the notes C–D–E or C–E–G; and E is often used as a reciting note.

**Gallican Confession**, Latin *CONFESSIO GALLICANA*, statement of faith adopted in 1559 in Paris by the first National Synod of the Reformed Church of France. Based on a 35-article draft of a confession prepared by John Calvin, which he sent with representatives from Geneva to the French synod, the draft was revised by his pupil Antoine de la Roche Chandieu. The Gallican Confession consisted of 35 articles divided into four sections concerning God, Christ, the Holy Spirit, and the church. It affirmed that the Bible is the only rule of faith. It also included an exposition on predestination, the doctrine that God elects or chooses who will be saved, and stated Calvin's doctrine of the Eucharist.

Subsequently, a preface was added to the confession, and it was presented to King Francis II of France in 1560. At La Rochelle, Fr., in 1571, during the seventh National Synod of the Reformed Church of France, the confession, amplified to 40 articles, was again ratified and was signed by all the delegates. The Gallican Confession has often been printed in French Bibles, and it remained the authoritative statement of faith for the French Reformed Church into the 19th century.

**Gallicanism**, a complex of French ecclesiastical and political doctrines and practices advocating restriction of papal power; it characterized the life of the Roman Catholic Church in France at certain periods.

Despite its several varieties, Gallicanism consisted of three basic ideas: independence of the French king in the temporal order; superiority of an ecumenical council over the pope; and union of clergy and king to limit the intervention of the pope within the kingdom. Though the word was coined in the 19th century to identify the position opposing Ultramontanism (*q.v.*), which emphasized papal authority, the doctrine itself had its roots in early French nationalism, especially in the organizing action of Charlemagne in the 8th and 9th centuries, and came to conscious flower in the 14th century.

The struggle between Philip IV the Fair and Pope Boniface VIII (1294–1303) demonstrated in striking fashion the conflict over

the nature of the royal and papal powers and their relationship. The next century and a half saw the development of the conciliar theory, according to which a general council draws its powers directly from Christ, even the pope being subject to its decisions. In this context two important events took place. First, during the attempts to end the Great Schism, when rival popes were established at Avignon and Rome, King Charles VI, following a national synod of bishops in 1398, decided to withdraw obedience from Benedict XIII, the pope of Avignon, without recognizing Boniface IX at Rome because he was no longer functioning for the common good of the people. Second, in 1438, during another national synod, Charles VII issued the Pragmatic Sanction of Bourges, a declaration of 23 articles affirming that the pope was subject to a general council and that his jurisdiction was conditioned by royal will. Though the popes from then on constantly urged the revocation of the pragmatic sanction, they did not succeed until 1516, when it was replaced by a concordat conceding the French king's right to nominate bishops.

By the end of the 16th century two kinds of Gallicanism, political and theological, could be distinguished. Political Gallicanism could be further divided into parliamentary and royal; royal Gallicanism designates the policy of the French kings in matters ecclesiastical, and parliamentary Gallicanism indicates the demands of the courts and legislature in dealing with church affairs.

The most notable champion of parliamentary Gallicanism was the jurist Pierre Pithou, who published his *Les Libertés de l'église gallicane* in 1594. This book, together with several commentaries on it, was condemned by Rome but continued to be influential well into the 19th century.

The best expression of theological Gallicanism was found in the Four Gallican Articles, approved by the assembly of the clergy of France in 1682. This declaration stated: (1) the pope has supreme spiritual but no secular power; (2) the pope is subject to ecumenical councils; (3) the pope must accept as inviolable immemorial customs of the French Church—e.g., the right of secular rulers to appoint bishops or use revenues of vacant bishoprics; (4) papal infallibility in doctrinal matters presupposes confirmation by the total church. Bishop Jacques-Bénigne Bossuet drafted the declaration in Latin and defended it in a conciliatory preamble. Though the articles were condemned at Rome by Alexander VIII in 1690 and were revoked in France by Louis XIV in 1693, they remained the typical expression of Gallicanism.

Not all the French clergy were Gallican; the French Jesuits, in particular, were fervently Ultramontane. The 18th century, with its Rationalist attack on the very foundations of Catholicism, weakened the French concern for Gallicanism, and the Revolution left it enervated. Napoleon, though he favoured the clerical Gallican Party, had no strong interest. The first Vatican Council (1869–70) dealt a final blow by formally declaring the Ultramontane position.

**Gallicum Fretum** (English Channel): see Dover, Strait of.

**Gallieni, Joseph-Simon** (b. April 24, 1849, Saint-Béat, Fr.—d. May 27, 1916, Versailles), French army officer figure who successfully directed the pacification of the French Sudan and Madagascar and the integration of those African territories into the French colonial empire.

After training at the military academy of Saint-Cyr and serving in the Franco-German War (1870–71), Gallieni was sent to Africa in the mid-1870s. As a captain in 1881 he

was captured by the forces of the amir Ahmadou in the Upper Niger region, but within a year he had extracted exclusive privileges for France in that area.

Gallieni  
H. Roger-Vollet

After serving in Martinique, Gallieni was named governor of the French Sudan, where he successfully combated rebel Sudanese forces. In 1892–96 he served in French Indochina and then was sent to Madagascar. There he suppressed the revolt of monarchist forces and served as governor general until 1905, winning a reputation as a judicious, flexible, and humane colonial master who combined affection for the indigenous people with a sense of duty and innovation.

Gallieni was the logical choice for supreme commander of the French Army in 1911, but advanced age and poor health led him to decline in favour of Gen. Joseph Joffre. Gallieni retired in April 1914 only to be recalled that August, just before the outbreak of World War I, as military commander of Paris. Rather than remain a passive figure, he launched an important counterattack against the German armies as they crossed the Marne in September. He became minister of war in October 1915 and served with distinction until ill health forced his retirement in March 1916.

In 1921 he was posthumously raised to the dignity of marshal.

**Gallienus, Publius Licinius Egnatius** (b. c. 218—d. 268), Roman emperor jointly with his father, Valerian, from 253 until 260, then sole emperor to 268.

Gallienus ruled an empire that was disintegrating under pressures from foreign invaders. The Senate proclaimed him co-emperor because it saw that no one man could run the vast military operations needed to defend the empire. Valerian took charge of the eastern frontiers, while Gallienus fought a series of campaigns against the Goths on the Rhine and defeated the Alemanni at Milan in 258. He next crushed the successive revolts of Ingenuus and Regalianus in Illyricum. In June

Gallienus, marble bust; in the Museo Archeologico Nazionale, Naples  
Alinari—Art Resource/EB Inc

260 Valerian was taken prisoner by the Persian king Shāpūr I and died in captivity. At a time when independent rulers were asserting themselves across the empire, Odaenathus, prince of a Roman colony in the East, adhered to Rome, defeated Shāpūr, and quelled the usurping emperor Quietus at Emesa (now Homs, Syria). Gallienus subsequently named Odaenathus governor of all the East. The Persians devastated the East just as the Germanic tribes had recently plundered the Rhine and Danube provinces. Gallienus himself was left in control only of Italy and the Balkans. Toward the end of his reign, the Goths renewed their attacks, and the Emperor's defensive manoeuvres were interrupted by the revolt of a usurper, Aureolus. While besieging the insurgent general in Milan, Gallienus was murdered; his cavalry commander, Claudius, succeeded him as Claudius II.

Several developments during Gallienus' reign are of particular importance. There was a sharp reduction of civilian control over the military after Gallienus—breaking with a tradition of some seven centuries—transferred the command of the Roman armies from the senators to professional equestrian officers. At the same time, he expanded the role of the cavalry in warfare by creating a mobile cavalry reserve, which was to become the nucleus of the field army of the later empire. Finally, in the relatively peaceful years 262–267, Gallienus sponsored a vigorous intellectual renaissance at Rome. This revival is clearly discernible in the surviving art and the contemporary literature, notably that of Neoplatonist philosophers such as Plotinus.

**Gallifet, Gaston-Alexandre-Auguste, marquis de, PRINCE DE MARTIGUES** (b. Jan. 23, 1830, Paris—d. July 8, 1909, Par-

Gallifet, detail from a portrait by I. Pils, 1864; in the Musée de l'Armée, Paris  
Giraudon—Art Resource/EB Inc

is), French military leader who severely suppressed revolts in the Paris Commune in 1871.

Gallifet served with distinction at the Siege of Sevastopol (1854–55) during the Crimean War and in Emperor Napoleon III's wars in Algeria, Italy, and Mexico. As a brigade general during the Franco-German War (1870–71), he was captured at the Battle of Sedan. Assigned the task of suppressing Parisian revolts in 1871, he performed efficiently but with a severity that earned him the animosity of the political left, despite his own republicanism. By 1885 Gallifet was a member of the Conseil Supérieur de la Guerre (Supreme War Council) and had become a political protégé of Léon Gambetta, the moderate republican leader. In June 1899 Premier René Waldeck-Rousseau appointed Gallifet minister of war in order to balance the Cabinet that would support the Dreyfus revision. However, Gallifet was too eccentric and too ill suited for politics, and his role in the 1871 revolt undercut his effectiveness; within a year he was forced to leave his post.

**galliform**, order of birds (Galliformes) that comprises the gallinaceous (chickenlike) birds; there are about 240 species, including the

well-known chickens, pheasants, partridges, quail, and peafowl (family Phasianidae), turkeys (Meleagrididae), guinea fowl (Numididae), and grouse (Tetraonidae). Other, more exotic members of the order are the megapodes (Megapodiidae) of the Australasian region and the South American guans, curassows, and chachalacas (Cracidae). The aberrant South American hoatzin (Opisthocomidae) is sometimes placed in its own order, Opisthocomiformes.

A brief treatment of galliforms follows. For full treatment, see MACROPAEDIA: Birds.

Galliforms are heavy-bodied birds with short, rounded wings and strong, four-toed feet, adapted for life on the ground. All gallinaceous birds can fly, but none are long-distance fliers; they burst into quick, short flights to escape from predators. The galliforms are medium-sized birds, weighing from 1.5 ounces (45 g) in the painted quail to 24 pounds (11 kg) in the North American wild turkey. The coloration of females is usually drab, but the males frequently sport highly ornamental plumage.

The order is represented in most habitats on all the larger landmasses from the tropics to the subarctic; the ptarmigan (*Lagopus*) even live above the Arctic Circle. Phasianids have an almost worldwide distribution, while the turkeys are restricted to the Western Hemisphere. Grouse are found throughout the temperate and Arctic regions of both hemispheres, and guinea fowl are found only in Africa south of the Sahara.

Galliforms contain two of the birds of greatest economic importance to humankind. These are the chicken (*Gallus domesticus*), domesticated at least 4,000 years ago from the red jungle fowl (*G. gallus*), and the turkey. Chickens have been selectively bred to create varieties which produce upwards of 300 eggs a year; other heavy breeds have been developed for meat production. All turkeys are raised for rapid growth and a high meat yield. The guinea fowl is also raised domestically, but to a lesser extent than chickens or turkeys.

The majority of terrestrial game birds are members of this order. The common or ring-necked pheasant (*Phasianus colchicus*), which was introduced to North America, is well established and has become an important game species. Other species popular for sport are certain quail (especially *Coturnix* and *Colinus*) and partridges (*Perdix* and *Alectoris*).

Galliforms are mostly vegetarian, eating seeds, berries, leaves, and the like, but they also eat quantities of insects, worms, and other invertebrates. Many members of the group use their feet to scratch in the vegetation litter and uncover various food sources.

The gallinaceous birds show great variety in reproductive behaviour. Some galliforms are monogamous, while many others are polygamous. Monogamy appears in the megapodes, cracids, hoatzin, ptarmigan, guinea fowl, many quail and partridges, and some pheasants. Other pheasants, peafowl, and many grouse are polygamous. In social displays of grouse, the males congregate yearly on a dancing arena, or lek. Each male uses a small area of the lek, where he struts and calls to attract females, which visit the dancing arena and select a male to copulate with.

Most gallinaceous birds construct a very limited nest, usually a shallow hole in the ground with a lining of grass or leaves. The only birds that nest in trees are the hoatzin, the cracids, and the horned pheasant (*Tragopan*). The Megapodiidae, however, have a nesting system different not only from the other galliforms but also from all other birds. They are unique in relying on the heat from solar radiation or fermentation of plant matter to carry out the incubation of their eggs. Some species simply bury the egg in the sand at depths up to three feet (one metre) and pay no further attention to it. When hatched, the young megapodes can dig their way out and forage alone. Other

megapodes, such as the mallee fowl, construct mounds of decaying vegetation in which they lay their eggs.

Galliforms lay anywhere from two to two dozen eggs. In pheasants, the smaller birds lay from 12 to 20 eggs, but large forms like the great argus may lay only 2. Turkeys and guinea fowl lay between 7 and 20 eggs in a clutch. Most members of the order are indeterminate layers, which explains why they are so useful in commercial egg production. Incubation is usually the task of the female.

Except for the hoatzin, gallinaceous chicks are extremely precocious, following the parent and feeding within hours of hatching. The down-covered chicks are protectively coloured but still undergo high mortality rates due to predation.

**Gallimard, Gaston** (b. Jan. 18, 1881, Paris, Fr.—d. Dec. 25, 1975, Paris), French publisher whose firm was one of the most influential publishing houses of the 20th century.

The son of a wealthy art collector, Gallimard studied law and literature at the University of Paris and turned to journalism soon afterward. In 1908, with André Gide and Jean Schlumberger, he founded the literary review *La Nouvelle Revue Française*, a periodical of high intellectual standards. In 1911 the three men established a publishing house for the works of contributors to their review. This firm was called La Nouvelle Revue Française—Librairie Gallimard until 1919, when it became simply Librairie Gallimard. It became the foremost French publishing house of the 20th century, with major works by Gide, Marcel Proust, André Malraux, Jean-Paul Sartre, Albert Camus, and many lesser French authors. The firm also published the well-known *La Pléiade* series of French literary classics (acquired 1933) as well as the *Série Noire*, a series of some 2,000 thrillers, detective novels, and spy stories.

Gallimard eventually relinquished the daily administration of the company to his son Claude and grandson Christian. During his lifetime, the firm numbered 18 Nobel Prize winners among its regular authors, and its books garnered 25 Goncourt Prizes.

**gallinule**, any of several species of marsh birds belonging to the rail family, Rallidae, in the order Gruiformes. Gallinules occur in temperate, tropical, and subtropical regions worldwide and are about the size of bantam hens but with a compressed body like the re-

Purple gallinule (*Porphyryla martinica*)

Ruth Corderon from Root Resources—EB Inc

lated rails and coots. They are about 30 to 45 cm (12 to 18 inches) long, with long, thin toes that enable them to run over floating vegetation and with a prominent frontal shield (a fleshy plate on the forehead). Many species have brightly coloured areas of plumage or skin.

Gallinules are noisy and inquisitive birds, less furtive in their actions than most rails. Many are migratory. They build bulky nests of rushes on or near the water.

The common gallinule (*Gallinula chloropus*), blackish with a scarlet frontal shield, is called the moorhen or water hen where it occurs in Europe and Africa. Its North American

race (*G. chloropus cachinnans*) is sometimes known as the Florida gallinule.

The purple gallinule of America (*Porphyryla martinica*), sometimes called water hen or sultana, is about 30 cm long and is bright olive green and purplish blue with a light blue shield, red and yellow bill, and yellow legs and feet. It is found from South Carolina and Texas to northern Argentina. A related species is the lesser purple gallinule (*P. alleni*), of Africa.

The purple gallinule (*Porphyrio porphyrio*), sometimes called purple swamphen, is about 45 cm long. It occurs around the Mediterranean region and is widely distributed in Africa, southern Asia, and Australia.

Of the many peculiar flightless island forms throughout the world, some, such as the takahe (*q.v.*), are nearly extinct and others have become extinct recently.

**Gallio, Junius**, original name LUCIUS ANNAEUS NOVATUS (b. c. 5 BC, Corduba, Baetica [now Córdoba, Spain]—d. AD 65), Roman official who dismissed the charges brought by the Jews against the apostle Paul (Acts 18:12–17).

The elder brother of the philosopher and tragedian Lucius Annaeus Seneca, Novatus assumed the name Gallio after his adoption by the senator Junius Gallio. Upon the accession of the emperor Claudius (reigned 41–54), Gallio probably accompanied his illustrious brother into exile on the island of Corsica, Seneca having fallen victim to the intrigues of Claudius' wife, Messalina. The two brothers evidently returned to Rome in 49, when Claudius' new wife, Agrippina the Younger, selected Seneca to be tutor to the emperor Nero (reigned 54–68). The episode involving the apostle Paul, which occurred when Gallio was serving as proconsul of Achaia (in Greece) in 51, indicates that Roman provincial officials at that time were remaining aloof from the struggle between the Jews and the new Christian religion. He became consul in 55. After Nero forced Seneca to commit suicide, Gallio also took his own life.

**Gallipoli**, Turkish GELBOLU, historically CALLIOPOLIS, seaport and town, European Turkey. It lies on a narrow peninsula where the Dardanelles opens into the Sea of Marmara, 126 miles (203 km) west-southwest of Istanbul. An important Byzantine fortress, it was the first Ottoman conquest (c. 1356) in Europe and was maintained as a naval base because of its strategic importance for the defense of Istanbul. It was also a key transit station on the trade routes from Rumelia (Ottoman possessions in the Balkans) to Anatolia. In World War I, Gallipoli was the scene of determined Turkish resistance to the Allied forces during the Dardanelles Campaign (*q.v.*), in which most of the town was destroyed. A storehouse of the Byzantine emperor Justinian (6th century), a 14th-century square castle attributed to the Ottoman sultan Bayezid I, and mounds known as the tombs of Thracian kings still stand.

The new town, developed as a fishing and sardine-canning centre, is connected by road and steamer service with Istanbul and is also linked by road with Edirne. Pop. (1990 prelim.) 18,052.

**Gallipoli Peninsula** (Turkey): see Chersonese, Thracian.

**Gallipolis**, city, seat (1803) of Gallia county, southern Ohio, U.S., on the Ohio River, near its junction with the Kanawha River, 30 mi (48 km) north-northeast of Huntington, W.Va. The third oldest European settlement in Ohio, it was founded in 1790 by the Scioto Company for Royalists fleeing the French Revolution who had been deceived by agents of the

company into purchasing land certificates that were worthless. The company later, however, financed a settlement at the site, and some French moved there. The name means "city of the Gauls." During the American Civil War its strategic location resulted in economic prosperity; troops were channeled through the city, warehouses were built, and river traffic on the Ohio River increased.

Gallipolis is the shipping centre for a farming and coal-mining region and has light industry. Rio Grande College/Community College (1876) is 12 miles (19 km) northwest. Just south of the city is a large roller dam (1938) that raises the navigable depth of the Ohio River for 50 miles (80 km) and uplifts the Kanawha for 30 miles (50 km). A division of Wayne National Forest lies west and south of Gallipolis. Inc. village, 1842; city, 1865. Pop. (1990) 4,831.

**Gallitzin, Demetrius Augustine** (b. Dec. 22, 1770, The Hague, Neth.—d. May 6, 1840, Loretto, Pa., U.S.), one of the first Roman Catholic priests to serve as a missionary to European immigrants in the United States during the early 19th century. He was known as the "Apostle of the Alleghenies."

Of noble Russian parentage (his father was Prince Dmitry Alekseyevich Golitsyn, Russian ambassador to the Dutch Republic), Gallitzin converted to Roman Catholicism in 1787. He traveled to the United States and was ordained priest in Baltimore, Md., in 1795. John Carroll, first U.S. bishop, sent him to Cambria county, Pennsylvania, where immigrant Roman Catholics were settling in the Allegheny foothills. Like many of his peers, he was deeply engrossed in land and colony projects to attract Roman Catholic immigrants. At his death, when he was vicar general for western Pennsylvania, about 10,000 Roman Catholics lived in his district, where 40 years earlier there had been only 12.

Gallitzin wrote controversial tracts and pamphlets defending Roman Catholicism against attacks by frontier Protestants; typical of these polemics is *A Defence of Catholic Principles* (1816). A collection of his letters was published in 1940.

**BIBLIOGRAPHY.** Daniel Sargent, *Mitri* (1945), is a well-documented biography.

**gallium** (Ga), chemical element, metal of main Group IIIa, or boron group, of the periodic table. It liquefies just above room temperature.

Gallium was discovered (1875) by Paul-Émile Lecoq de Boisbaudran, who observed its principal spectral lines while examining material separated from zinc blende. Soon afterward he isolated the metal and studied its properties, which coincided with those that Dmitry Ivanovich Mendeleev had predicted a few years earlier for eka-aluminum, the then undiscovered element lying between aluminum and indium in his periodic table.

Though widely distributed at the Earth's surface, gallium does not occur free or concentrated in independent minerals, except for gallite,  $\text{CuGa}_2\text{S}_3$ , rare and economically insignificant. It is extracted as a by-product from zinc blende, iron pyrites, bauxite, and germanite.

Silvery white and soft enough to be cut with a knife, gallium takes on a bluish tinge because of superficial oxidation. Unusual for its low melting point (about 30° C [86° F]), gallium also expands upon solidification and supercools readily, remaining a liquid at temperatures as low as 0° C (32° F). Gallium remains in the liquid phase over a temperature range of about 2,000° C (about 3,600° F) with a very low vapour pressure up to about 1,500° C (about 2,700° F), the longest useful liquid range of any element. The liquid metal

clings to or wets glass and similar surfaces. The crystal structure of gallium is orthorhombic. Natural gallium consists of a mixture of two stable isotopes: gallium-69 (60.4 percent) and gallium-71 (39.6 percent).

Somewhat similar to aluminum chemically, gallium slowly oxidizes in moist air until a protective film forms, and it becomes passive in cold nitric acid. Gallium does not react with water at temperatures up to 100° C (212° F) but reacts slowly with hydrochloric and other mineral acids to give the gallium ion,  $\text{Ga}^{3+}$ . Gallium is amphoteric, reacting with sodium and potassium hydroxide solutions to yield a gallate and hydrogen gas. The halogens attack it vigorously.

In most of its compounds gallium has an oxidation state of +3 and, in a few, +1. There is no evidence for authentic gallium(II) compounds. The "dihalides," for example, contain monovalent and trivalent gallium in a one-to-one ratio. With the main Group V elements—phosphorus, arsenic, and antimony—gallium forms compounds that have semiconductor properties. Gallium antimonide, GaSb, and gallium arsenide, GaAs, are used in electronic devices to perform such functions as voltage rectification and amplification. The arsenide and the phosphide, GaP, are electroluminescent; the arsenide emits infrared light, while the phosphide radiates in the visible spectrum.

Gallium has been considered as a possible heat-exchange medium in nuclear reactors, although it has a high neutron cross section. Radioactive gallium-72 shows some promise in the study of bone cancer; a compound of this isotope is absorbed by the cancerous portion of the bone.

atomic number	31

**Galloway**, traditional region, southwestern Scotland, composed of the districts of Wigtown, Stewartry, and part of Nithsdale, Dumfries and Galloway region. Until 1975 it was part of the counties of Kirkcudbright (east Galloway) and Wigtown (west Galloway). It is bounded by the districts of Kyle and Carrick and Cumnock and Doon Valley on the north, the Solway Firth on the southeast, and the North Channel, the narrowest point (26 miles [42 km]) between Scotland and Ireland, on the southwest.

The Rinn (or Rhinn), a hammer-shaped 210-foot- (64-metre-) high peninsula in the extreme southwest of Wigtown, surmounted by a 60-foot (18-metre) lighthouse, is the most southerly point in Scotland.

The name Galloway is derived from the Gallgaidhel, or Gallwyddel ("Stranger Gaels"), the original Celtic people of this region, called Novantae by the Romans. The last "king" of Galloway died in 1234, and during the 14th century the Balliols and Comyns were the chief families, succeeded about 1369 by the Douglases (until 1458) and in 1623 by the Stewarts. The 17th-century Scottish Presbyterians known as the Covenanters found much support throughout the region.

Galloway's economy is predominantly pastoral in the lowlands, based on dairy farming of the indigenous black, hornless cattle called Galloway cattle. The moor areas above 500 feet (150 m) elevation have undergone afforestation and now provide hope for the establishment of a forest industry (including a pulp and paper mill). The Galloway Hydro-Electric Scheme (1935) harnessed the waters of the Rivers Dee and Ken for the generation of hydroelectricity. With the former county of Dumfriesshire, it is included in the South West Scotland Development Area.

**Galloway, Joseph** (b. c. 1731, West River, Md. [U.S.]—d. Aug. 29, 1803, Watford, Hertfordshire, Eng.), distinguished American colonial attorney and legislator who remained loyal to Great Britain at the time of the American Revolution (1775–83). His effort in 1774 to settle differences peacefully narrowly missed adoption by the Continental Congress. He was, perhaps, the greatest of the colonial Loyalists.

Entering law practice in Philadelphia in 1747, Galloway early won a reputation by pleading cases before the Supreme Court of Pennsylvania before he was 20. Elected to the provincial assembly in 1756, he occupied the powerful post of speaker from 1766 to 1775. His "A plan of a proposed Union between Great Britain and the Colonies" in 1774 provided for a president general to be appointed by the king and a colonial legislature to have rights and duties similar to the House of Commons. After a day's debate his plan was rejected by the Continental Congress by only one vote and was later expunged from the record.

In the belief that the Revolution was unreasonable and unjust, Galloway left Philadelphia and joined General Sir William Howe's British army. He returned to the city as a civil administrator during the British occupation. He drew up several plans of union after the Declaration of Independence with the hope that they might be used when the rebels had been defeated. With the reentry of the Continentals into Philadelphia in 1778 he fled to England, where he remained until his death.

**gallstone**, concretion composed of crystalline substances (usually cholesterol, bile pigments, and calcium salts) imbedded in a small amount of protein material formed most often in the gallbladder. The most common type of gallstone consists principally of cholesterol. Its occurrence has been linked to secretion by the liver of bile that is saturated or supersaturated with cholesterol and contains abnormally low levels of bile salts and lecithin, which in normal bile are present in sufficient quantities to keep cholesterol in solution.

Predisposing factors to the development of gallstones (cholelithiasis) are inflammation and stagnation resulting from liver damage, chronic gallbladder disease, or cancer of the biliary tract. Stones located in the gallbladder may produce no clinical symptoms, or they may set up an inflammatory process, producing acute inflammation of the gallbladder (cholecystitis, *q.v.*). When a stone becomes lodged in the bile ducts, obstruction leads to increased pressure above the site of blockage, resulting in the severe pain known as biliary colic.

Gallstones sometimes pass into the intestines spontaneously, but in most instances they must be removed by surgery or dissolved by ultrasonic therapy. The gallbladder itself is sometimes removed during surgery to prevent further stone production. In some cases, cholelithiasis can be treated medically by feeding the patient bile salts to dissolve gallstones and reduce the concentration of cholesterol in the bile.

**Gallup**, city, seat (1901) of McKinley county, northwestern New Mexico, U.S., on the Puerco River, near the Arizona state line. Settled in 1880 as a Westward Overland Stagecoach stop, it became a construction headquarters for the Atlantic and Pacific Railroad and was named for David L. Gallup, railroad paymaster. It flourished with the discovery of coal and in 1895 became a railroad divisional terminal. Situated between the Navajo (north) and Zuni (south) Indian reservations (with many pre-Columbian ruins), it is the area headquarters of the Bureau of Indian Affairs. A shipping point for cattle, wool, hides, and forest products, it has light industries with emphasis on Indian arts and crafts. Tourism is important, and the Inter-Tribal Indian Ceremonial is held

annually in August. A branch of the University of New Mexico is in the city. Inc. 1891. Pop. (1990) 19,154.

**Gallup, George (Horace)** (b. Nov. 18, 1901, Jefferson, Iowa, U.S.—d. July 26, 1984, Tschingel, Switz.), U.S. public-opinion statistician whose Gallup Poll became almost a generic title for public opinion sample surveys. Popular faith in public-opinion polls was greatest after 1936, when Gallup, Elmo Roper, and Archibald Crossley, acting independently but using similar methods of sampling, forecast Franklin D. Roosevelt's victory over Alfred M. Landon in the U.S. presidential election.

Gallup taught journalism at Drake University, Des Moines, Iowa, and Northwestern University, Evanston, Ill., until 1932, when an advertising firm in New York City hired him to conduct public-opinion surveys on behalf of its clients. He founded the American Institute of Public Opinion in 1935, the British Institute of Public Opinion in 1936, and the Audience Research Institute, Inc., in 1939. Although, along with other pollsters, Gallup incorrectly predicted Pres. Harry S. Truman's defeat in the U.S. presidential election of 1948, the percentage of error was small; subsequent predictions were more correct or more cautious.

Gallup wrote several books, including *The Pulse of Democracy* (1940) and *The Sophisticated Poll Watcher's Guide* (rev. ed., 1976). He also founded the Quill and Scroll, an international honour society for high school journalists.

**gallus** (ancient priest): *see* galli.

**Gallus, Gaius Cornelius** (b. c. 70 BC, Forum Julii, Gaul—d. 26 BC, Egypt), Roman soldier and poet, famous for four books of poems to his mistress "Lycoris" (the actress Volumnia, stage name Cytheris), which, in ancient opinion, made him the first of the four greatest Roman elegiac poets.

Gallus was a friend of Augustus and Virgil and, having distinguished himself in the war against Mark Antony, was made governor of Egypt. There, however, his imprudent conduct led to his disgrace and suicide. Quintilian ranked him with Tibullus, Propertius, and Ovid as one of the great Roman elegists. Virgil celebrated him, and Parthenius dedicated to Gallus his book on unhappy love affairs.

*Where the same name may denote a person, place, or thing, the articles will be found in that order*

**Gallus, Gaius Vibius Trebonianus** (d. 253, near Interamna, Latium), Roman emperor from 251 to 253.

Gallus came from an ancient family of Perusia (modern Perugia, Italy), whose ancestry could be traced to the pre-Roman Etruscan aristocracy. He served the emperor Decius with loyalty and distinction as legate of Moesia and was proclaimed emperor after the defeat and death (June 251) of Decius at the hands of the Goths. Gallus then concluded a treaty with the enemy. He adopted Decius' son Hostilian as his co-ruler and at the same time made his own son, Volusianus, a secondary and later co-emperor. Hostilian died of plague shortly after receiving his title. The Goths renewed their attacks early in 253, and the armies of Moesia proclaimed their commander, Aemilian, emperor. Gallus summoned Valerian, commander of the armies of the Upper Rhine, to his aid but was killed by his own troops before Valerian arrived.

**Gallus, Jacobus:** *see* Handl, Jacob.

**Gallus, Quintus Roscius:** *see* Roscius.

**Gallus Caesar**, byname of FLAVIUS CLAUDIUS CONSTANTIUS (b. 325/326,

Etruria—d. 354, near Pola), ruler of the eastern provinces of the Roman Empire, with the title of caesar, from 351 to 354.

Sources dating from this period describe Gallus' reign at Antioch (modern Antakya, Tur.) as tyrannical. His father, Julius Constantius, was the half brother of Constantine the Great, and Gallus was the elder half brother of the emperor Julian the Apostate and cousin of the emperor Constantius II. Like Julian, with whom he grew up, he was given a strict Christian education. Constantius II proclaimed him caesar at Sirmium (modern Sremska Mitrovica, Yugos.) on March 15, 351, and also arranged Gallus' marriage to his (Constantius') sister, Constantia. But Gallus' strict, isolated upbringing had made him stern and tactless. He instituted a widespread system of espionage among his subjects and executed a number of people—not all unjustly—on suspicion of treason. Meanwhile, he was suppressing revolts in Palestine and in Isauria, Galatia (in south-central Anatolia), and holding the Persians at bay. His subordinates sent unfavourable and sometimes misleading reports about him to Constantius, prompting the Emperor to recall Gallus to Constantinople, to strip him of his powers, and finally to have him executed.

**Galois, Évariste** (b. Oct. 25, 1811, Bourg-la-Reine, near Paris—d. May 31, 1832, Paris), French mathematician famous for his contributions to the part of higher algebra known as group theory. His theory solved many longstanding unanswered questions, including the impossibility of trisecting the angle and squaring the circle.

Galois was the son of Nicolas-Gabriel Galois, an important citizen in the Paris suburb of Bourg-la-Reine. In 1815, during the Hundred Days regime that followed Napoleon's escape from Elba, his father was elected mayor. Galois's mother, Adelaïde-Marie Demante, was of a distinguished family of jurists. She educated Galois at home until 1823, when he entered the Collège Royal de Louis-le-Grand. There his education languished at the hands of mediocre and uninspiring teachers. But his mathematical ability suddenly appeared when he was able to master quickly the works of Adrien-Marie Legendre on geometry and Joseph-Louis Lagrange on algebra.

Under the guidance of Louis Richard, one of his teachers at Louis-le-Grand, Galois's further study of algebra soon led him to take up a major challenge. Mathematicians for a long time had used explicit formulas, involving only rational operations and extractions of roots, for the solution of equations up to degree four. (For example,  $3x^2 + 5 = 17$  is an equation of the second degree, since it contains the exponent 2; solving an equation of

terms whose coefficients appear in the equation.) The solution of quadratic, or second degree, equations goes back to ancient times. Formulas for the cubic and quartic were published in 1545 by Gerolamo Cardano, Italian mathematician and physician, after their discovery a few years earlier by the mathematicians Niccolò Tartaglia and Ludovico Ferrari. The equation of the fifth degree then defeated mathematicians until Paolo Ruffini in 1796 attempted to prove the impossibility of solving the general quintic equation by radicals. Ruffini's effort was not wholly successful, but the Norwegian mathematician Niels Abel in 1824 gave an essentially correct proof.

Galois was unaware of Abel's work in the first stages of his investigation, although he did learn of it later. This was perhaps fortunate because Galois actually had launched himself on a much more ambitious study; while yet a student, at about age 16, he sought, by what is now called the "Galois theory," a deeper understanding of the essential conditions that an equation must satisfy in order for it to be solvable by radicals. His method was to analyze the "admissible" permutations (a change in an ordered arrangement) of the roots of the equation. That is, in today's terminology, he formed the "group" of automorphisms (a particular kind of transformation) of the "field," obtained by adjoining the roots of the equation. His key discovery, brilliant and highly imaginative, was that solvability by radicals is possible if and only if the group of automorphisms is solvable, which means essentially that the group can be broken down into prime-order constituents (prime numbers are positive numbers greater than 1 divisible only by themselves and 1) that always have an easily understood structure. The term solvable is used because of this connection with solvability by radicals. Thus Galois perceived that solving equations of the quintic and beyond required a wholly different kind of treatment than that required for the quadratic, cubic, and quartic.

While still at Louis-le-Grand he published several minor papers. Soon disappointments and tragedy filled his life with bitterness. Three memoirs that he submitted to the Academy of Sciences were lost or rejected by the academicians, who as mathematicians were authorized to act as editors. The first was lost in 1829 by Augustin-Louis Cauchy. In each of two attempts (1827 and 1829) to enter the École Polytechnique, the leading school of French mathematics, he had a disastrous encounter with an oral examiner and failed. Then his father, after bitter clashes with conservative elements in his hometown, committed suicide in 1829. The same year, realizing that his career possibilities as a professional mathematician had ended, Galois enrolled as a teacher candidate in the less prestigious École Normale Supérieure and turned to political activism. But he continued his research.

A second memoir, on algebraic functions, which he submitted in 1830 to the Academy of Sciences, was lost by Jean-Baptiste-Joseph Fourier. The revolution of 1830 sent the last Bourbon monarch, Charles X, into exile. But republicans were deeply disappointed when yet another king, Louis-Philippe, ascended the throne—even though he was a citizen king who wore the tricolour of the Revolution. When Galois wrote a vigorous article expressing these views, he was promptly expelled from the École Normale Supérieure. Subsequently he was arrested twice for republican activities; he was acquitted the first time but spent six months in prison on the second charge. His third memoir in 1831 was returned by Siméon-Denis Poisson with a note that it was virtually incomprehensible and should be expanded and clarified.

Galois, detail of an engraving, 1848, after a drawing by Alfred Galois

this type is called a solution by radicals, because it involves extracting the square root of an expression composed of one or more

The circumstances that led to Galois's death in a duel in Paris have never been fully explained. It has been variously suggested that it resulted from a quarrel over a woman, that he was challenged by royalists who detested his republican views, or that an agent provocateur of the police was involved. Alexandre Dumas, in his autobiography *Mes Mémoires* (1863–65), implicated Pécheux d'Herbenville as the man who shot Galois. In any case, anticipating his death in the coming duel, Galois in feverish haste wrote a scientific last testament addressed to his friend and former schoolmate Auguste Chevalier. In his distracted notes, there are hints that Galois had begun to develop the theory of algebraic functions, the full development of which was achieved 40 years later by the German mathematician Bernhard Riemann.

Galois's manuscripts, with annotations by Joseph Liouville, were published in 1846 in the *Journal de Mathématiques Pures et Appliquées*. In 1870 the French mathematician Camille Jordan published the full-length treatment of Galois's theory, *Traité des Substitutions*. These works rendered his discoveries fully accessible and his place secure in the history of mathematics. On June 13, 1909, a plaque was placed on Galois's modest birthplace at Bourg-la-Reine, and the mathematician Jules Tannery made an eloquent speech of dedication, which was published the same year in the *Bulletin des Sciences Mathématiques*. (I.K.)

**BIBLIOGRAPHY.** Paul Dupuy, *La Vie d'Evariste Galois*, published in the *Annales Scientifiques de l'École Normale Supérieure*, 3rd Series, vol. 13, pp. 197–266 (1896), is the basic biographical work. See also Eric Temple Bell, *Men of Mathematics*, ch. 20 (1937, reprinted 1961), for a highly readable biographical sketch, featuring strong opinions of the establishment's disastrous mistreatment of Galois. The *Écrits et mémoires mathématiques*, ed. by Robert Bourgne and J.-P. Azra with a preface by J. Dieudonné (1962), contains all the available writings of Galois, with a running commentary, and reproduces photographically many pages of his original manuscripts. A historic survey is B. Melvin Kiernan, "The Development of Galois Theory from Lagrange to Artin," *Arch. Hist. Exact Sci.*, 8:40–154 (1971). Brief, elegant, and self-contained is Emil Artin, *Galois Theory*, 2nd ed. (1944).

**galop**, lively social dance allegedly of German origin, popular in 19th-century England and France. The man put his right hand around his partner's waist and with his left hand held her right; the couple danced the galop's simple step side by side—slide, close, slide—around the ballroom to music in  $\frac{3}{4}$  time. The galop's spirited rhythm occurs in the finale of

"The Last Galop," engraving by W.S. Palmer, Sr., after a drawing by Frederick Barnard

The Bettmann Archive

Ponchielli's *Dance of the Hours* and in many ballets, where the basic step is elaborated for theatrical effect.

**Galswintha**, French GALSWINTHE (b. c. 540, Spain—d. 568, Neustria), daughter of Athanagild, Visigothic king of Spain; sister of Brunhild, queen of Austrasia; and wife of Chilperic I, the Merovingian king of Neustria. Galswintha and Chilperic were married at Rouen in 567, but soon afterward she was murdered at the instigation of Chilperic's mistress Fredegund, who then married him. Galswintha's death aroused the enmity of her sister Brunhild, wife of King Sigebert I of Austrasia, against Chilperic and precipitated 40 years of warfare between the Frankish kingdoms of Austrasia and Neustria.

**Galsworthy, John** (b. Aug. 14, 1867, Kingston Hill, Surrey, Eng.—d. Jan. 31, 1933, Grove Lodge, Hampstead), English novelist and playwright, winner of the Nobel Prize for Literature in 1932.

Galsworthy's family, of Devonshire farming stock traceable to the 16th century, had made a comfortable fortune in property in the 19th century. His father was a solicitor. Educated at Harrow and New College, Oxford, Galswor-

Galsworthy, oil painting by Rudolf Sauter, 1923, in the University of Birmingham Library, England

By courtesy of Rudolf Sauter

thy was called to the bar in 1890. With a view to specializing in marine law, he took a voyage around the world, during which he encountered Joseph Conrad, then mate of a merchant ship. They became lifelong friends. Galsworthy found law uncongenial and took

to writing. For his first works, *From the Four Winds* (1897), a collection of short stories, and the novel *Jocelyn* (1898), both published at his own expense, he used the pseudonym John Sinjohn. *The Island Pharisees* (1904) was the first book to appear under his own name. *The Man of Property* (1906) began the novel sequence to be known as *The Forsyte Saga*, the long chronicle novel by which Galsworthy is chiefly remembered; others in the same series are "Indian Summer of a Forsyte" (1918, in *Five Tales*), *In Chancery* (1920), *Awakening* (1920), and *To Let* (1921). The story of the Forsyte family after World War I was continued in *The White Monkey* (1924), *The Silver Spoon* (1926), and *Swan Song* (1928), collected in *A Modern Comedy* (1929). Galsworthy's other novels include *The Country House* (1907), *The Patrician* (1911), and *The Freelanders* (1915).

Galsworthy was also a successful dramatist, his plays, written in a naturalistic style, usually examining some controversial ethical or social problem. They include *The Silver Box* (1906), which, like many of his other works, has a legal theme and depicts a bitter contrast of the law's treatment of the rich and the poor; *Strife* (1909), a study of industrial relations; *Justice* (1910), a realistic portrayal of prison life that roused so much feeling that it led to reform; and *Loyalties* (1922), the best of his later plays. He also wrote verse.

In 1905 Galsworthy married Ada Pearson, the divorced wife of his first cousin, A.J. Galsworthy. Galsworthy had, in secret, been closely associated with his future wife for about ten years before their marriage. Irene in *The Forsyte Saga* is to some extent a portrait of Ada Galsworthy, although her first husband was wholly unlike Soames Forsyte.

A television serial of *The Forsyte Saga* by the British Broadcasting Corporation achieved immense popularity in Great Britain in 1967 and later in many other nations, especially the United States, reviving interest in an author whose reputation had plummeted after his death.

**Galt, Sir Alexander Tilloch** (b. Sept. 6, 1817, London—d. Sept. 19, 1893, Montreal), Canadian statesman and influential early advocate of federation.

Galt emigrated from England to Sherbrooke, Lower Canada (later Canada East, now in Quebec), in 1835 and worked for the British American Land Company, serving as high commissioner from 1844 to 1855. In this role he built up an understanding with the eastern townships and the English-speaking minority of Canada East. He gave active support to the promotion of the St. Lawrence and Atlantic and the Grand Trunk railways. He entered politics in 1849 as an independent member for Sherbrooke County in the legislature of the united province of Canada. Reflecting the opinion of his English-speaking constituents, he did not support the bill compensating citizens for losses incurred by French-Canadians during their 1837 rebellion. He favoured annexation by the United States in order to achieve Anglo-Saxon ascendancy over the French Roman Catholic majority in Canada East and, more overtly, to promote economic growth. He resigned from the legislature in 1850 but was reelected for Sherbrooke town in 1853; he maintained that seat and remained leader of the English-speaking minority until 1872.

In 1858 Galt declined a ministry in the brief George Brown–Sir Antoine Aimé Dorion administration, but that same year he became minister of finance in the Sir John Macdonald–Sir George Étienne Cartier government on condition that federation of British North American provinces be government policy. As finance minister (1858–62, 1864–67) Galt adopted a policy of protection for the Cana-

dian manufacturers. He supported the Macdonald–Brown–Cartier coalition, which advocated federation (1864), and worked on the necessary negotiations at the Charlottetown,

Sir Alexander Galt, 1890

Montreal

P.E.I.; Quebec; and Westminster conferences; he was knighted for his services in 1869.

Following the creation of the Dominion of Canada (1867), Galt was first finance minister of the Dominion government, but he resigned after a disagreement with Macdonald. He declined further Cabinet office but gave intermittent support to the government until retiring from Parliament in 1872. He then began to advocate Canadian independence as an ultimate goal. He served as first Canadian high commissioner in London from 1880 to 1883, after which he retired from public life.

**Galt, John** (b. May 2, 1779, Irvine, Ayrshire, Scot.—d. April 11, 1839, Greenock, Renfrewshire), prolific Scottish novelist admired for his depiction of country life.

Galt settled in London in 1804. Commissioned by a merchant firm to establish trade agreements, he travelled to the Mediterranean area, where he met the poet Byron, with whom he travelled to Malta and later to Athens. (In 1830 he published *Life of Lord Byron*.) Other commercial ventures took him to France and The Netherlands (1814) and to Canada (1826). He opened up a road between Lakes Huron and Erie through the forest country and founded the city of Guelph in Upper Canada (now Ontario) in 1827. His position with the Canada Land Company was undermined by enemies, and he returned home practically a ruined man. All his life he had been a voluminous writer, and he now devoted himself entirely to literature.

His masterpieces are *The Ayrshire Legatees* (1820), *The Annals of the Parish* (1821), *Sir Andrew Wylie* (1822), *The Provost* (1822), *The Entail* (1823), and *Lawrie Todd* (1830),

Edinburgh

novels of Scottish rural life that foreshadowed the Kailyard (kitchen garden) school (*q.v.*) of fiction of the late 19th century. The *Ayrshire Legatees* tells, in the form of letters to their friends in Scotland, the adventures of the Rev.

Pringle and his family in London. *The Annals of the Parish*, told by the Rev. Micah Balwhidder, Galt's finest character, is a humorous and truthful picture of the old-fashioned Scottish pastor and the life of a country parish. And in the novel *Lawrie Todd* the hard life of a Canadian settler is depicted with imaginative power.

**Galton, Sir Francis** (b. Feb. 16, 1822, near Sparkbrook, Birmingham, Warwickshire, Eng.—d. Jan. 17, 1911, Grayshott House, Haslemere, Surrey), English explorer, anthropologist, and eugenicist, known for his pioneering studies of human intelligence. He was knighted in 1909.

*Early life.* Galton's family life was happy, and he gratefully acknowledged that he owed much to his father and mother. But he had little use for the conventional classical and religious teaching he received in school and church. Indeed, he later confessed in a letter to Charles Darwin that the traditional biblical arguments had made him "wretched."

Galton, detail of an oil painting by G. Graef, 1882; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

His parents had planned that he should study medicine, and a tour of medical institutions on the Continent in his teens—an unusual experience for a student of his age—was followed by training in hospitals in Birmingham and London. But at this time, in Galton's words, "a passion for travel seized me as if I had been a migratory bird." A visit to the University of Giessen, Germany, to attend lectures on chemistry was broken off in favour of travel in southeastern Europe. From Vienna he made his way through Constanza, Constantinople, Smyrna, and Athens, and he brought back from the caves of Adelsberg (present-day Postojina, Slovenia) specimens of a blind amphibian named *Proteus*—the first to reach England. On his return Galton went to Trinity College, Cambridge, where, as a result of overwork, he broke down in his third year. But he recovered quickly on changing his mode of life, as he did from similar attacks later.

*Travels and exploration.* After leaving Cambridge without taking a degree, Galton continued his medical studies in London. But before they were completed, his father died, leaving him "a sufficient fortune to make me independent of the medical profession." Galton was then free to indulge his craving for travel. Leisurely expeditions in 1845–46 up the Nile with friends and into the Holy Land alone were preliminaries to a carefully organized penetration into unexplored parts of southwestern Africa. After consulting the Royal Geographical Society, Galton decided to investigate a possible opening from the south and west to Lake Ngami, which lies north of the Kalahari desert some 550 miles east of Walvis Bay. The expedition, which included two journeys, one northward, the other eastward, from the same base, proved to be difficult and not without

danger. Though the explorers did not reach Lake Ngami, they gained valuable information. As a result, at the age of only 31, Galton was in 1853 elected a fellow of the Royal Geographical Society and, three years later, of the Royal Society. In 1853, too, Galton married. There were no children of the marriage. Galton wrote 9 books and some 200 papers. They deal with many diverse subjects, including the use of fingerprints for personal identification, the correlational calculus (a branch of applied statistics)—in both of which Galton was a pioneer—twins, blood transfusions, criminality, the art of travel in undeveloped countries, and meteorology. Most of Galton's publications disclose his predilection for quantifying; an early paper, for example, dealt with a statistical test of the efficacy of prayer. Moreover, over a period of 34 years, he concerned himself with improving standards of measurement.

*Advocacy of eugenics.* Although he made contributions to many fields of knowledge, eugenics remained Galton's fundamental interest, and he devoted the latter part of his life chiefly to propagating the idea of improving the physical and mental makeup of the human species by selective parenthood. Galton, a cousin of Charles Darwin, was among the first to recognize the implications for mankind of Darwin's theory of evolution. He saw that it invalidated much of contemporary theology and that it also opened possibilities for planned human betterment. Galton coined the word eugenics to denote scientific endeavours to increase the proportion of persons with better than average genetic endowment through selective mating of marriage partners. In his *Hereditary Genius* (1869), in which he used the word genius to denote "an ability that was exceptionally high and at the same time inborn," his main argument was that mental and physical features are equally inherited—a proposition that was not accepted at the time. It is surprising that when Darwin first read this book, he wrote to the author: "You have made a convert of an opponent in one sense for I have always maintained that, excepting fools, men did not differ much in intellect, only in zeal and hard work." This book doubtless helped Darwin to extend his evolution theory to man. Galton, unmentioned in *Origin of Species* (1859), is several times quoted in Darwin's *Descent of Man* (1871). Galton's conviction that mental traits are no less inherited than are physical characteristics was strong enough to shape his personal religious philosophy. "We cannot doubt," he wrote, "the existence of a great power ready to hand and capable of being directed with vast benefit as soon as we have learned to understand and apply it."

Galton's *Inquiries into Human Faculty* (1883) consists of some 40 articles varying in length from 2 to 30 pages, which are mostly based on scientific papers written between 1869 and 1883. The book can in a sense be regarded as a summary of the author's views on the faculties of man. On all his topics, Galton has something original and interesting to say, and he says it with clarity, brevity, distinction, and modesty. Under the terms of his will, a eugenics chair was established at the University of London.

*Reputation.* In the 20th century Galton's name has been mainly associated with eugenics. Insofar as eugenics takes primary account of *inborn* differences between human beings, it has come under the suspicion of those who hold that cultural (social and educational) factors heavily outweigh *inborn*, or biological, factors in their contribution to human differences. Eugenics is accordingly often treated as an expression of class prejudice, and Galton as a reactionary. Yet to some extent this view misrepresents his thought, for his aim was not

the creation of an aristocratic elite but of a population consisting entirely of superior men and women. His ideas, like those of Darwin, were limited by a lack of an adequate theory of inheritance; the rediscovery of the work of Mendel came too late to affect Galton's contribution in any significant way.

**BIBLIOGRAPHY.** The most important work on Galton is Karl Pearson, *The Life, Letters, and Labours of Francis Galton*, 3 vol. in 4 (1914–30). A shorter treatment is found in D.W. Forrest, *Francis Galton* (1974).

**Galty Mountains**, also spelled GALTEE MOUNTAINS, mountain range, extending across the border between southwestern County Tipperary and southeastern County Limerick, southern Ireland. The range has the east–west trend characteristic of the extreme south of the country. The highest peaks are formed of sandstone, the highest point being Galtymore (3,018 feet [920 m]). The mountains bear strong evidence of glaciation, notably in the form of corries (ice-scooped basins) with lakes and block moraines (mounds of glacial debris impeding drainage).

**Galuppi, Baldassare**, byname IL BURANELLO (b. Oct. 18, 1706, island of Burano, near Venice [Italy]—d. Jan. 3, 1784, Venice), Italian composer whose comic operas won him the title “father of the opera buffa.” His nickname derives from his birthplace, Burano.

Galuppi was taught by his father, a barber and violinist, and studied under A. Lotti in

Galuppi, oil painting by an unknown artist  
The Andre Meyer Collection—J.P. Ziolo

Venice. After producing two operas in collaboration with G.B. Pescetti (1728–29), he began composing operas for Venetian theatres. In 1741 he visited London and arranged a *pasticcio*, titled *Alexander in Persia*. Several of his own operas were produced in England, including *Enrico* (1743), and the contemporary music historian Charles Burney wrote of his considerable influence on English composers. In 1748 he became assistant concertmaster at San Marco Basilica in Venice and in 1762 concertmaster there. From 1766 to 1768 he was chapelmaster to Catherine II in Russia, where he composed *Ifigenia in Tauride* (“Iphigenia in Tauris”), an opera seria. In 1768 he returned to Venice and resumed his duties at San Marco.

Of Galuppi's comic operas, *Il filosofo di campagna* (1754; “The Country Philosopher”) was the most popular. He was one of the earliest composers of opera to use the ensemble finale, in which all the characters appear in a musical ensemble that carries the action forward to the end of the act. Besides operas, Galuppi wrote religious and instrumental works.

**Galut** (Judaism): see Diaspora.

**Galvani, Luigi** (b. Sept. 9, 1737, Bologna, Papal States [Italy]—d. Dec. 4, 1798, Bologna, Cisalpine Republic), Italian physician and physicist who investigated the nature and effects of what he conceived to be electricity in animal tissue. His discoveries led to the inven-

Galvani, detail of an engraving by A. Marchi after a drawing by F. Spagnoli  
By courtesy of the Museum National d'Histoire Naturelle, Paris

tion of the voltaic pile, a kind of battery that makes possible a constant source of current electricity.

**Early years.** Galvani followed his father's preference for medicine by attending the University of Bologna, graduating in 1759. On obtaining the doctor of medicine degree, with a thesis (1762) *De ossibus* on the formation and development of bones, he was appointed lecturer in anatomy at the University of Bologna and professor of obstetrics at the separate Institute of Arts and Sciences. In 1762, also, he married Lucia, the only daughter of Professor Galeazzi of the Bologna Academy of Science, of which Galvani became president in 1772. Beginning with his doctoral thesis, his early research was in comparative anatomy—such as the structure of renal tubules, nasal mucosa, and the middle ear—with a tendency toward physiology, a direction appropriate to the later work for which he is noted. Galvani's developing interest was indicated by his lectures on the anatomy of the frog in 1773 and in electrophysiology in the late 1770s, when, following the acquisition of an electrostatic machine (a large device for making sparks) and a Leyden jar (a device used to store static electricity), he began to experiment with muscular stimulation by electrical means. His notebooks indicate that, from the early 1780s, animal electricity remained his major field of investigation. Numerous ingenious observations and experiments have been credited to him; in 1786, for example, he obtained muscular contraction in a frog by touching its nerves with a pair of scissors during an electrical storm. Again, a visitor to his laboratory caused the legs of a skinned frog to kick when a scalpel touched a lumbar nerve of the animal while an electrical machine was activated. Galvani assured himself by further experiments that the twitching was, in fact, related to the electrical action. He also elicited twitching without the aid of the electrostatic machine by pressing a copper hook into a frog's spinal cord and hanging the hook on an iron railing. Although twitching could occur during a lightning storm or with the aid of an electrostatic machine, it also occurred with only a metallic contact between leg muscles and nerves leading to them. A metallic arc connecting the two tissues could therefore be a substitute for the electrostatic machine.

**Electrical nature of nerve impulse.** Galvani delayed the announcement of his findings until 1791, when he published his essay *De Viribus Electricitatis in Motu Musculari Commentarius* (*Commentary on the Effect of Electricity on Muscular Motion*). He concluded that animal tissue contained a heretofore neglected innate, vital force, which he termed “animal electricity,” which activated nerve and muscle when spanned by metal probes. He believed that this new force was a form of electricity in addition to the “natural” form that is produced by lightning or by the electric eel and

torpedo ray and to the “artificial” form that is produced by friction (i.e., static electricity). He considered the brain to be the most important organ for the secretion of this “electric fluid” and the nerves to be conductors of the fluid to the nerve and muscle, the tissues of which act as did the outer and inner surfaces of the Leyden jar. The flow of this electric fluid provided a stimulus for the irritable muscle fibres, according to his explanation.

Galvani's scientific colleagues generally accepted his views, but Alessandro Volta, the outstanding professor of physics at the University of Pavia, was not convinced by the analogy between the muscle and the Leyden jar. Deciding that the frog's legs served only as an indicating electroscope, he held that the contact of dissimilar metals was the true source of stimulation; he referred to the electricity so generated as “metallic electricity” and decided that the muscle, by contracting when touched by metal, resembled the action of an electroscope. Furthermore, Volta said that, if two dissimilar metals in contact both touched a muscle, agitation would also occur and increase with the dissimilarity of the metals. Thus Volta rejected the idea of an “animal electric fluid,” replying that the frog's legs responded to differences in metal temper, composition, and bulk. Galvani refuted this by obtaining muscular action with two pieces of the same material. But the ensuing controversy was without personal animosity; Galvani's gentle nature and Volta's high principles precluded any harshness between them. Volta, who coined the term galvanism, said of Galvani's work that “it contains one of the most beautiful and most surprising discoveries.” Nevertheless, partisan groups rallied to both sides.

In retrospect, Galvani and Volta are both seen to have been partly right and partly wrong. Galvani was correct in attributing muscular contractions to an electrical stimulus but wrong in identifying it as an “animal electricity.” Volta correctly denied the existence of an “animal electricity” but was wrong in implying that every electrophysiological effect requires two different metals as sources of current. Galvani, shrinking from the controversy over his discovery, continued his work as teacher, obstetrician, and surgeon, treating both wealthy and needy without regard to fee. In 1794 he offered a defense of his position in an anonymous book, *Dell'uso e dell'attività dell'arco conduttore nella contrazione dei muscoli* (“On the Use and Activity of the Conductive Arch in the Contraction of Muscles”), the supplement of which described muscular contraction without the need of any metal. He caused a muscle to contract by touching the exposed muscle of one frog with a nerve of another and thus established for the first time that bioelectric forces exist within living tissue.

**Last years.** On June 30, 1790, Galvani's devoted wife and companion died, childless, at the age of 47. In the last years of his life, Galvani refused to swear allegiance to the new Cisalpine Republic established by Napoleon. Thereupon he was dropped from the faculty rolls, and his salary was terminated. Rejecting help and much saddened, he moved into the old Galvani home in which his brother was living. Soon, however, the politicians recanted, and the professorship was again offered to Galvani without the requirement of an oath. But the affront had cut short his days: Galvani died in the house of his birth at age 61, at a time when the world was on the threshold of the great electrical revolution.

Galvani provided the major stimulus for Volta to discover a source of constant current electricity; this was the voltaic pile, or a battery, with its principles of operation combined from chemistry and physics. This discovery led to the subsequent age of electric power. Moreover, Galvani opened the way to new re-

search in the physiology of muscle and nerve and to the entire subject of electrophysiology. (B.Di.)

**BIBLIOGRAPHY.** Luigi Galvani, *Opere edite ed inedite del professore Luigi Galvani* (1841) and *Aggiunta*, ed. by Silvestro Gherardi (1842), comprise a prime reference; *Memorie ed esperimenti inediti di Luigi Galvani* (1937), Galvani's laboratory notes; *Commentary on the Effect of Electricity on Muscular Motion* (1953), an English translation of Galvani's *De Viribus Electricitatis in Motu Musculari Commentarius* (1791), with facsimile of the Latin text, an introduction by I. Bernard Cohen, and an extensive bibliography; C. Mesini, Luigi Galvani (1958), a clear and scholarly modern study (in Italian).

**galvanic skin response:** see psychogalvanic reflex.

**galvanizing**, protection of iron or steel against exposure to the atmosphere and consequent rusting by application of a zinc coating. Properly applied, galvanizing may protect from atmospheric corrosion for 15 to 30 years or more. As discontinuities or porosity develop in the coating, galvanic or electrolytic action ensues; the iron or steel, however, is protected by sacrificial corrosion, a phenomenon in which, as long as the zinc and the iron are in contact, atmospheric oxidation spares the iron and affects the zinc.

Zinc may be applied by two general methods: hot dipping and electrolytic deposition.

In hot-dip processes, cleaned iron or steel, usually in sheet form, is passed through a flux such as a zinc-ammonium chloride and guided through a bath of molten zinc. In wire galvanizing, the wire is drawn through successive pickling, annealing, and washing operations. It is dried before passing into the galvanizing pan and is drawn out through wipers of charcoal, coke, sand, or asbestos.

In one hot-dip process, intermetallic compounds of iron and zinc are formed on the surface of the steel or iron being treated by heating it in the presence of finely divided zinc below the melting point of the zinc. In another, molten zinc is applied in a fine spray to the surface of the cleaned iron or steel; the zinc adheres tightly to the surface.

In electrolytic deposition, or electroplating, a pure coating of completely controlled thickness of zinc may be applied without heat. More care is required, and for articles that must be made watertight, the electrolytic processes do not have the soldering effect of the hot processes. The zinc coating, however, has greater adherence than that formed in the hot-dip process. See also sherardizing.

**galvanometer**, instrument for measuring a small electrical current or a function of the current by deflection of a moving coil. The deflection is a mechanical rotation derived from forces resulting from the current.

The most common type is the D'Arsonval galvanometer, in which the indicating system consists of a light coil of wire suspended from a metallic ribbon between the poles of a permanent magnet. The magnetic field produced by a current passing through the coil reacts with the magnetic field of the permanent magnet, producing a torque, or twisting force. The coil, to which an indicating needle or mirror is attached, rotates under the action of the torque; the angle through which it rotates to balance the torsion of the suspension provides a measure of the current flowing in the coil. The angle is measured by the movement of the needle or by the deflection of a beam of light reflected from the mirror.

The ballistic galvanometer is designed to deflect its indicating needle (or mirror) in a way that is proportional to the total charge passing through its moving coil or to a voltage pulse of short duration. Any conventional galvanometer may also be employed as a ballistic type, but the latter has smaller torque and higher inertia in the coil.

**galvanoplasty** (technology): see electroforming.

**Galveston**, city, seat (1838) of Galveston county, southeastern Texas, U.S., 51 mi (82 km) southeast of Houston. It is a major deep-water port on the Gulf Intracoastal Waterway, at the northeast end of Galveston Island, which extends along the Texas coast for about 30 mi, separating Galveston Bay and West Bay from the Gulf of Mexico. The French explorer La Salle visited the island in 1686 and named it St. Louis for his sovereign, but it remained unoccupied except by Karankawa Indians. In 1777 troops of Bernardo de Gálvez, Spanish governor of Louisiana (later viceroy of Mexico), temporarily occupied the island and named it Gálvez (whence Galveston). The pirate Jean Lafitte made the place his headquarters (1817-21). Settlement of the island then began, and in 1834 Michel B. Menard organized the Galveston City Company and laid out a townsite. During the Texas revolt against Mexico (1835-36), the four ships that comprised the Texas Navy ("Invincible," "Brutus," "Liberty," and "Independence") were based at Galveston, which briefly, prior to the successful outcome of the Battle of San Jacinto (April 21, 1836), served as the capital of the republic after the temporary president, David Burnet, arrived there with his cabinet. During the Civil War Galveston was an important Confederate supply port; it was captured by a Federal fleet in October 1862 but was retaken by Confederates a few months later. Two factors dislodged it from its leading commercial position: the rise of competitive Texas ports, notably Houston, and a destructive hurricane on Sept. 8, 1900, in which more than 5,000 lives were lost and much of the city was destroyed. After this disaster, a protective seawall 17 ft (5 m) high and 10 mi long was built, paralleled by a wide boulevard overlooked by hotels. The wall broke the force of a powerful hurricane in September 1961 and reduced flood damage.

Shipping, oil refining, food processing, and resort business are major economic assets. Chief exports are cotton, grain, and sulfur; imports include sugar, tea, and bananas. Galveston offers ship repairing, including nuclear-service facilities. The island is connected to the mainland by causeways, and a superhighway gives rapid access to Texas City, Houston, and other communities. Access from the northeast is by ferry from Bolivar Peninsula across Galveston Harbor. The city is the site of the University of Texas Medical Branch (1891), Moody College of Marine Sciences and Maritime Resources (1971); affiliated with Texas A&M University, and Galveston College (1966). Inc. 1839. Pop. (2000) city, 57,247; Galveston-Texas City PMSA, 250,158.

**Galveston Bay**, inlet of the Gulf of Mexico, on the southeastern shore of Texas, U.S. Protected from the Gulf by the Bolivar Peninsula and Galveston Island, the bay is 35 mi (56 km) long and up to 19 mi wide; it receives the Trinity and San Jacinto rivers. The Houston Ship Channel provides deepwater access both to the Gulf (between Bolivar Peninsula and Pelican and Galveston islands) and to Houston (via the San Jacinto River). The bay supplies oyster shells for use in cement making, and, most importantly, it offers safe anchorage for ships serving the heavily populated and industrialized Houston-Galveston area. The Gulf Intracoastal Waterway passes through its southeastern portion, and the shipping of petroleum and chemical products is prominent. Fishery resources in the bay have declined because of pollution, but Galveston still maintains a large fishing and shrimp fleet, which operates in Gulf waters. The bay was named in July 1785 by José de Evíá, a Spanish pilot, who surveyed the Gulf Coast by order of Bernardo de Gálvez, governor of Louisiana (and later viceroy of Mexico).

**Gálvez, José, MARQUÉS** (marquess) DE LA SONORA (b. 1720, Vélez-Málaga, Spain—d. 1787, Aranjuez), Spanish colonial administrator particularly noted for his work as inspector general (*visitador general*) in New Spain (Mexico), 1765-71. Among his important accomplishments were the reorganization of the tax system, the formation of a government tobacco monopoly, the reorganization of the defenses of the northern frontier of the Viceroyalty, and the occupation of Upper California. On completion of his inspection, he recommended further administrative and fiscal reforms, the most important of which, the intendency system, was introduced in 1786. Subsequently, he was named minister of the Indies (1775) and was granted the title of marqués de la Sonora (1785).

**Gálvez, Manuel** (b. July 18, 1882, Paraná, Arg.—d. Nov. 14, 1962, Buenos Aires), novelist and biographer, whose documentation of a wide range of social ills in Argentina in the first half of the 20th century earned him an important position in modern Spanish-American literature.

Gálvez studied law at the National University of Buenos Aires, graduating in 1904 and making that city his permanent residence. He was an inspector of secondary education from 1906 to 1931. He founded (1903) and directed the literary magazine *Ideas* and visited Europe on several occasions.

Gálvez is best remembered for his realistic novels of Argentinian life, which deal with conflict in urban society. In *La maestra normal* (1914; "The Schoolmistress"), his first and generally considered his best novel, he captures the pettiness and monotony of life in a small Argentinian city before the quickening pace of modernity shattered old provincial ways. In his later years, Gálvez turned to historical novels and novelized biographies of Argentinian figures, which, despite their popular success, were less enthusiastically received by the critics than his earlier realistic fiction.

**Galvin, George** (entertainer): see Leno, Dan.

**Galway**, Irish GALLIMH, county in the province of Connaught (Connacht), western Ireland. With an area of 2,293 sq mi (5,939 sq km), it is bounded on the north by Mayo and Roscommon and Tipperary, on the east by Roscommon and Offaly, on the south by Clare and Tipperary, and on the west by the Atlantic Ocean. The eastern two-thirds of Galway is part of the Irish central lowland. In the west is Connemara (*q.v.*), mainly a lowland, with peat bogs, many lakes, heathlands, and uplands such as the Twelve Bens and the Maumturk Mountains, with many summits higher than 2,000 ft (600 m). The descendants of the followers of the Norman Richard de Burgh, who assumed rule of Connaught in the 1230s, became known as the tribes of Galway. The county was given its shire boundaries in the reign of Elizabeth I. After 1652 the land settlement of Oliver Cromwell established a new class of landed proprietors.

Galway has the largest Gaelic-speaking element of any Irish county; the Irish college at Spiddal has facilities for those wishing to learn Gaelic. About one-third of the county's people live in towns and villages. Apart from the town of Galway, the towns are small. There are a county council and a county manager; Galway town is a county borough.

The living conditions in Connemara are among the hardest in Ireland. Most of the people live on small farms in a coastal belt about one mile wide. In the east, areas of cultivable soil are used for crops or for the rich pastures that often develop in this area of high rainfall. Sheep are kept in large numbers. Rough woodlands, patches of rocky heath, and peat

bogs create gaps in the pattern of agricultural settlement. Only a few short streams flow over much of the lowland, but there are numerous shallow depressions called turloughs that provide good pastures in dry periods. Galway produces a black marble and a green-streaked Connemara marble of great beauty. Other industries include boot making in Ballinasloe, cotton spinning in Loughrea, and sugar refining in Tuam. Pop. (1996) 180,364.

**Galway**, Irish GAILLIMH, seaport and county town (seat) of County Galway, Ireland, on the northern shore of Galway Bay.

After the building of its walls by Anglo-Norman settlers (c. 1270), it developed as a commercial centre and had considerable trade with Spain. The charter of incorporation given by Richard II (reigned 1377–99) was extended in 1545 to give the port jurisdiction over the Aran Islands; it permitted export of all goods except linens and woollens. The town and land within a 2-mi (3-km) radius were established as a county by charter in the reign of James I (1603–25). The town was captured by Parliamentary forces during the English Civil War and again during the campaigns of William III. There are remains of a Franciscan friary (founded 1296), and the town is the seat of a Roman Catholic diocese. St. Nicholas' Church dates from 1320. University College, founded in 1849 as Queen's College, received a new charter in 1908 as a college of the National University of Ireland. Claddagh, the Irish part of the town in Norman times, is now a suburb.

The chief exports are wool, agricultural produce, marble, china, and various metals. The main industries are flour milling, ironworking, and the manufacture of hats, furniture, refrigeration units, computers, electric motors, medical instruments, and sports equipment. A shipping service connects Galway with the Aran Islands, 20 mi (32 km) southwest. Pop. (1996) 50,853.

**Galway, Henri de Massue**, MARQUIS DE RUVIGNY ET RAINEVAL, also called (1692–97) VISCOUNT GALWAY, BARON PORTARLINGTON (b. April 9, 1648, Paris—d. Sept. 3, 1720, Hampshire, Eng.), French soldier who became a trusted servant of the British king William III.

Viscount Galway, detail of a portrait by I. Simon after a painting by Philip De Graves (17th century)  
By courtesy of the National Gallery of Ireland, Dublin

Massue began his career as aide-de-camp to Marshal Turenne (1672–75), then went on diplomatic mission to England (1678). After the revocation of the Edict of Nantes (1685), Massue, a prominent Huguenot, along with his father and brother, settled in England in 1688. In 1690 he forfeited his French estates by entering the English army as major general of horse; he fought with distinction in the Irish campaign and was created Viscount Galway in 1692.

One of the few men absolutely trusted by William III, he was nevertheless resented among English politicians because of his foreign birth. In 1694 he was appointed to command the allied armies in Savoy, and in 1697 he received an earldom and was sent as lord justice to Ireland. Feeling unsuited to politics, he happily retired in 1701, but in 1704 he was called out of retirement to command the allied forces in Portugal during the War of the Spanish Succession. After a decisive defeat at Almansa (April 1707), he again retired, only to be recalled again to act as lord justice of Ireland (1715–16).

**Gama, (José) Basilio da** (b. 1740, São José do Rio das Mortes, Braz.—d. July 31, 1795, Lisbon), neoclassical poet and author of the Brazilian epic poem *O Uruguai* (1769), an account of the Portuguese-Spanish expedition against the Jesuit-controlled reservation Indians of the Uruguay River basin.

Gama completed his novitiate with the Jesuits in 1759. In that same year the order was expelled from Brazil and all other Portuguese possessions, and he eventually left Brazil for Rome. On his return to Brazil in 1767 he was sent by the Inquisition to Lisbon where, as a Jesuit, he faced deportation to Angola. He won his pardon from the chief minister of the realm, the marquês de Pombal, by composing a poem for Pombal's daughter's wedding; he subsequently became Pombal's protégé. The anti-Jesuit theme of the published version of *O Uruguai*, the original version of which had been openly pro-Jesuit, was no doubt Gama's supreme gesture to establish himself in the good graces of his new patrons.

In spite of its questionable historicity, the poem became the most important Brazilian work of the colonial period. Gama shows himself to be a sensitive and original poet in breaking away from the strict epic model established by Luis de Camões, Portugal's great 16th-century poet, and creating a Brazilian epic in blank verse. He substitutes descriptions of indigenous animism and fetishism for the standard classical mythology of the epic genre and elaborates vivid and moving scenes of Indian life and the Brazilian natural environment. His poem opened the way for the romantic nationalism that was to flower in 19th-century Brazilian literature.

**Gama, Vasco da**, 1<sup>er</sup> CONDE (1st count) DA VIDIGUEIRA (b. c. 1460, Sines, Port.—d. Dec. 24, 1524, Cochin, India), Portuguese navigator whose voyages to India (1497–99, 1502–03, 1524) opened up the sea route from western Europe to the East by way of the Cape of Good Hope and thus ushered in a new era in world history. He also helped make Portugal a world power.

*Life.* The third son of Estêvão da Gama, a nobleman who was commander of the fortress of Sines on the coast of Alentejo province in southwestern Portugal, Vasco was born in about 1460. Little is known of his early life; he may have studied at the inland town of Évora—somewhere he learned mathematics and navigation. In 1492 King John II of Portugal sent him to the port of Setúbal, south of Lisbon, and to the Algarve, Portugal's southernmost province, to seize French ships in retaliation for French peacetime depredations against Portuguese shipping—a task that Vasco rapidly and effectively performed.

In accordance with the policy of Prince Henry the Navigator, King John was planning to send a Portuguese fleet to India to open the sea route to Asia and to outflank the Muslims, who had hitherto enjoyed a monopoly of trade with India and other eastern states. Estêvão da Gama was chosen to lead the expedition, but after his death Vasco took his place. Accounts of his appointment differ; whether he was chosen by King John and this choice confirmed by King Manuel, who ascended the throne in 1495, or whether it was King Manuel who

"Knight of the Order of Christ," identified as Vasco da Gama, detail, Portuguese school, first half of the 16th century; in the Museu Nacional de Arte Antiga, Lisbon

By courtesy of the Museu Nacional de Arte Antiga, Lisbon

first chose him, remains unclear. According to one version, the appointment was first offered to his eldest brother Paulo, who declined because of ill health.

*The first voyage.* Da Gama sailed from Lisbon on July 8, 1497, with a fleet of four vessels—two medium-sized three-masted sailing ships, each of about 120 tons, named the "São Gabriel" and the "São Rafael"; a 50-ton caravel, named the "Berrio"; and a 200-ton storeship. They were accompanied to the Cape Verde Islands by another ship commanded by Bartolomeu Dias, the Portuguese navigator who had discovered the Cape of Good Hope a few years earlier and who was en route to the West African castle of São Jorge da Mina on the Gold Coast (now Ghana). With da Gama's fleet went three interpreters—two Arabic speakers and one who spoke several Bantu dialects. The fleet also carried *padrões* (stone pillars) to set up as marks of discovery and overlordship.

Passing the Canary Islands on July 15, the fleet reached the São Tiago in the Cape Verde Islands on the 26th, remaining there until August 3. Then, to avoid the currents of the Gulf of Guinea, da Gama took a circular course through the South Atlantic to the Cape of Good Hope, reaching Santa Helena Bay (in modern South Africa) on November 7. The expedition departed on November 16, but unfavourable winds delayed their rounding of the Cape of Good Hope until November 22. Three days later da Gama anchored in Mossel Bay, erected a *padrão* on an island, and ordered the storeship to be broken up. Sailing again on December 8, the fleet reached the coast of Natal on Christmas Day. On Jan. 11, 1498, it anchored for five days near the mouth of a small river between Natal and Mozambique, which they called the Rio do Cobre (Copper River). On January 25, in what is now Mozambique, they reached the Quelimane River, which they called the Rio dos Bons Sinais (the River of Good Omens), and erected another *padrão*. By this time many of the crews were sick with scurvy; the expedition rested a month while the ships were repaired.

On March 2 the fleet reached the island of Mozambique, the inhabitants of which believed the Portuguese to be Muslims like themselves. Da Gama learned that they traded with Arab merchants and that four Arab vessels laden with gold, jewels, silver, and spices were then in port; he was also told that Prester John, the long-sought Christian ruler, lived in the interior but held many coastal

cities. The Sultan of Mozambique supplied da Gama with two pilots, one of whom deserted when he discovered that the Portuguese were Christians.

The expedition reached Mombasa (now in Kenya) on April 7 and dropped anchor at Malindi (also now in Kenya) on April 14, where a pilot who knew the route to Calicut, on the southwest coast of India, was taken aboard. After a 23-day run across the Indian Ocean, the Ghâts Mountains of India were sighted, and Calicut was reached on May 20. There da Gama erected a *padrão* to prove he had reached India. Welcomed by the Zamorin, the Hindu ruler, of Calicut (then the most important trading centre of southern India), he failed, however, to conclude a treaty—partly because of the hostility of Muslim merchants and partly because the trumpery presents and cheap trade goods that he had brought, while suited to the West African trade, were hardly in demand in India.

After tension between da Gama's expedition and the Zamorin of Calicut increased, da Gama left at the end of August, taking with him five or six Hindus so that King Manuel might learn about their customs. He visited Anjdiv Island (near Goa) before sailing for Malindi, which he reached on Jan. 8, 1499. Unfavourable winds caused the expedition to take nearly three months crossing the Arabian Sea, and many of the crew died of scurvy. At Malindi, because of greatly reduced numbers, da Gama ordered the "São Rafael" to be burned; there he also erected a *padrão*. Mozambique, where he set up his last *padrão*, was reached on February 1. On March 20 the "São Gabriel" and "Berrio" rounded the Cape together but a month later were parted by a storm; the "Berrio" reached the Tagus River in Portugal on July 10. Da Gama, in the "São Gabriel," continued to Terceira Island in the Azores, whence he is said to have dispatched his flagship to Lisbon. He himself reached Lisbon on September 9 and made his triumphal entry nine days later, spending the interval mourning his brother Paulo, who had died on Terceira. Manuel I granted Vasco the title of *dom* (equivalent to the English "sir"), an annual pension of 1,000 cruzados, and estates.

*The second voyage.* To further da Gama's achievement, Manuel I dispatched the Portuguese navigator Pedro Álvares Cabral to Calicut with a fleet of 13 ships. Later, the Hindus, incited by the Muslims, rose in arms and massacred the Portuguese whom Cabral had left behind. To avenge this deed a new fleet was fitted out in Lisbon to be sent against Calicut and to establish Portuguese hegemony in the Indian Ocean. At first the command was to be given to Cabral, but it was later transferred to da Gama, who in January 1502 was given the rank of admiral. Da Gama himself commanded 10 ships, which were in turn supported by two flotillas of five ships each, each flotilla being under the command of one of his relations. Sailing in February 1502, the fleet called at the Cape Verdes, reaching the port of Sofala in East Africa on June 14. After calling briefly at Mozambique, the Portuguese expedition sailed to Kilwa, in what is now Tanzania. The ruler of Kilwa, the amir Ibrâhîm, had been unfriendly to Cabral; da Gama threatened to burn Kilwa if the Amir did not submit to the Portuguese and swear loyalty to King Manuel, which he then did.

Coasting southern Arabia, da Gama then called at Goa (later the focus of Portuguese power in India) before proceeding to Cannanore, a port in southwestern India to the north of Calicut, where he lay in wait for Arab shipping. After several days an Arab ship arrived with merchandise and between 200 and 400 passengers, including women and children. After seizing the cargo, da Gama shut up the passengers aboard the captured ship and set it afire, killing all on board, the cruelest act of his career.

After da Gama formed an alliance with the ruler of Cannanore, an enemy of the Zamorin, the fleet sailed to Calicut. The Zamorin offered friendship, but da Gama rejected the offer and presented an ultimatum that the Muslims be banished from the port. To show that he meant what he threatened, da Gama bombarded the port and seized and massacred 38 Hindu fishermen who had sailed out to his ships to sell their wares; their bodies were then thrown overboard, to be washed ashore. The Portuguese then sailed south to the port of Cochin, with whose ruler (an enemy of the Zamorin) they formed an alliance. After an invitation to da Gama from the Zamorin had proved to be an attempt to entrap him, the Portuguese had a brief fight with Arab ships off Calicut but put them to full flight. On Feb. 20, 1503, the fleet left Cannanore for Mozambique on the first stage of their return voyage, reaching the Tagus on October 11.

*The third voyage.* Obscurity surrounds the reception of da Gama on his return by King Manuel. Da Gama seemingly felt himself inadequately recompensed for his pains. Controversy broke out between the Admiral and the Order (*i.e.*, religious association) of São Tiago over the ownership of the town of Sines, which the Admiral had been promised but which the order refused to yield. Da Gama had married a lady of good family, Caterina de Ataíde—perhaps in 1500 after his return from his first voyage—and he then appears to have retired to the town of Évora. He was later granted additional privileges and revenues, and his wife bore him six sons. Until 1505 he continued to advise the King on Indian matters, and he was created count of Vidigueira in 1519. Not until after King Manuel died was he again sent overseas; King John III nominated him in 1524 as Portuguese viceroy in India.

Arriving in Goa in September, da Gama immediately set himself to correct the many administrative abuses that had crept in under his predecessors. Whether from overwork or other causes, he soon fell ill and died in Cochin in December. In 1538 his body was taken back to Portugal. (E.M.J.C.)

**BIBLIOGRAPHY.** There is no autobiography of Vasco da Gama. Portuguese chroniclers wrote at length about his voyage of 1497–99, and some of them must have had access to secret documents since destroyed. The only one translated into English is that of Gaspar Correa (*c.* 1490–1565) from his *Lendas da Índia*; see *The Three Voyages of Vasco da Gama, and His Viceroyalty*, ed. by Lord Stanley of Alderley (1869, reprinted 1963). The only firsthand account of the first voyage has also been printed in English in E.G. Ravensiein (ed.), *A Journal [by an Unknown Writer] of the First Voyage of Vasco da Gama, 1497–1499* (1898, reprinted 1963). A later and more definitive edition has been printed in Portuguese in Abel Fontoura da Costa (ed.), *Roteiro da Primeira Viagem de Vasco da Gama, 1497–1499 por Alvaro Velho*, 3rd ed. (1969). An outstanding synthesis of the background of Vasco da Gama's achievements is found in John H. Parry, *The Age of Reconnaissance: Discovery, Exploration and Settlement, 1450–1650*, 2nd ed. (1966). For brief accounts together with English translations of extracts from early documents, see John H. Parry (ed.), *The European Reconnaissance: Selected Documents* (1968). The unique manuscript copy of the three *Roteiros* (sailing directions) of Vasco da Gama's Arab pilot, Ahmad ibn Mâdjid, has not been fully translated and printed in English, but see A.G.R. Tibbetts, *Arab Navigation in the Indian Ocean Before the Coming of the Portuguese* (1971). For the definitive Portuguese translation of the Arab text, see T.A. Chumovsky (ed.), *Três Roteiros desconhecidos de Ahmad ibn Mâdjid* (1960).

**Gamagōri**, city, Aichi Prefecture (*ken*), Honshu, Japan, facing Mikawa-wan (Mikawa Bay). The city has been well known for the manufacture of cotton textiles since the Tokugawa era (1603–1867). Mandarin orange orchards grace the mountain slopes behind Gamagōri, which also serves as a seaside resort. There are

hot-spring spas nearby. The city is connected by bridge to offshore Take-shima (Take Island), which has a Shintō shrine dedicated to the goddess of beauty. Pop. (1995) 83,730.

**Gamaliel I**, also called **RABBAN GAMALIEL** (*rabban*, meaning "teacher") (fl. early 1st century AD), a tanna, one of a select group of Palestinian masters of the Jewish Oral Law, and a teacher twice mentioned in the New Testament.

According to tradition—but not historic fact—Gamaliel succeeded his father, Simon, and his grandfather, the renowned sage Hillel (to whose school of thought he belonged), as nasi (president) of the Sanhedrin, the supreme Jewish court. It is certain, though, that Gamaliel held a leading position in the Sanhedrin and that he enjoyed the highest repute as teacher of the Law; he was the first to be given the title rabban. Like his grandfather, Gamaliel also was given the title *ha-Zaqqen* (the Elder).

The New Testament (Acts 5:34–39) relates that Gamaliel intervened on behalf of the Apostles of Jesus when they had been seized and brought to the Sanhedrin, and another passage (Acts 22:3) tells how St. Paul, in a speech to the Jews, tried to influence them by stating that he had been a student of Gamaliel ("I am a Jew, . . . brought up . . . at the feet of Gamaliel").

Gamaliel established a number of lenient ordinances, in particular, laws affecting women and non-Jews. Of his teaching, only one saying is preserved in the Talmud; it enjoins the duties of study and scrupulous observance of religious ordinances. Gamaliel's renown is summed up in the words recorded in the Talmud: "When Rabban Gamaliel the Elder died, regard for the Torah [Jewish Law] ceased, and purity and piety died."

**Gamaliel II**, also called **GAMALIEL OF JABNEH** (fl. late 1st/early 2nd century AD), nasi (president) of the Sanhedrin, at that time the supreme Jewish legislative body, in Jabneh, whose greatest achievement was the unification of the important Jewish laws and rituals in a time of external oppression by Rome and internecine quarrels.

In the ancient biblical city of Jabneh, many Jews had taken refuge from the Roman siege of Jerusalem in AD 70. Gamaliel succeeded Johanan ben Zakkai as leader of a school of Judaism whose members inherited the authority of the Sanhedrin of Jerusalem. He strengthened the Jewish faith, which had been seriously weakened by the loss of the Temple and Sanhedrin in Jerusalem and by the Jewish loss of political autonomy.

Gamaliel ended the division of Jewish spiritual leaders—some of whom belonged to the school of Hillel and others to that of Sham-mai—by ruling that Hillel's more lenient interpretations of Jewish Law were authoritative. He devoted special attention to the regulation of prayer ritual, which had become all-important since the cessation of sacrificial worship. He gave the principal prayer, the *amida*, consisting of 18 (subsequently 19) benedictions, its final revision and declared that it was every Israelite's duty to recite it three times daily. By asserting his authority to standardize the Jewish calendar and thus fix the dates of festivals, Gamaliel further unified all Jews. He was recognized as patriarch (leader of the people) by Rome, and his reforms raised the power and prestige of the patriarchate.

During his administration, Gamaliel frequently became dictatorial toward dissenters; at one point, he excommunicated his own brother-in-law. Because of his harsh methods, he was deposed, but he was later restored to power. When he died, he was buried, according to his own wish, garbed in simple linen,

to discourage the expensive burials that had impoverished many Jewish families.

**Gamaliel III** (fl. first half of the 3rd century AD), eldest son of Judah ha-Nasi, and the renowned editor of the Mishna (the basic compilation of Jewish oral law).

A direct descendant of the sage Hillel, Gamaliel became patriarch of the Jewish community in Palestine in approximately AD 220 and, consequently, head of the Sanhedrin, the Jewish legislative body of that time. Beyond the fact that Gamaliel helped complete the Mishna, almost nothing else is known about him. Three of his sayings were incorporated in *Avot* ("Fathers"), a treatise of the Mishna, and there are a few scattered references to him in other postbiblical sources.

INDEX  
first

**Gambaga Scarp**, line of cliffs along the Volta River basin, northeastern Ghana, western Africa. The scarp forms the elevated northern boundary of the Volta River basin and the eastern section of the granite plateaus of Wa and Mamprusi. To the south is another narrow plateau, followed by a gradual descent of the surrounding land. The Gambaga's steep erosional scarps reveal a composition of nearly horizontal sandstones. Because of the elevation (1,000–1,500 feet [300–460 m]), the climate is relatively cool and moist, allowing cultivation of grains and yams and stock raising. The only sizable town on the plateau is Gambaga, originally a cotton-collecting centre and now a popular hill station. The only major road off the scarp runs from Gambaga to Walewale and from there to Kumasi.

**Gambetta, Léon** (b. April 2, 1838, Cahors, Fr.—d. Dec. 31, 1882, Ville-d'Avray, near Paris), French republican statesman who helped direct the defense of France during the Franco-German War of 1870–71. In helping to found the Third Republic, he made three essential contributions: first, by his speeches and articles, he converted many Frenchmen to the ideals of moderate democratic repub-

Gambetta, photograph by Étienne Carjat; in the Bibliothèque Nationale, Paris

By courtesy of the Bibliothèque Nationale, Paris

licanism. Second, by his political influence and personal social contacts, he gathered support for an elective democratic political party, the Republican Union. Finally, by backing Adolphe Thiers, who was elected provisional head of government by the National Assembly of 1871, against royalists and Bonapartists, he helped transform the new regime into a parliamentary republic. Gambetta was briefly premier of France from Nov. 14, 1881, to Jan. 16, 1882.

*Life.* Gambetta's mother was from Gascony; his father was an Italian who had emigrated to Cahors and had opened a grocery store there. A successful pupil at the local high school, ambitious and naturally eloquent, young Gambetta refused to stay in a provincial town with no other prospect than to work in his father's store. Against his father's will, he went to Paris to study law.

Gambetta professed very strongly republican opinions, and his exuberant and generous nature soon made him highly popular among the Paris students. In 1859 he was called to the bar, but he was unsuccessful as a lawyer until 1868, when a political case known as the *Affaire Baudin* made him suddenly famous. Jean-Baptiste Baudin, a deputy (legislator) killed resisting Napoleon III's coup d'état of 1851, had become a republican martyr, and eight journalists were being prosecuted for attempting to have a monument erected in his memory. As counsel of one of the accused, Gambetta delivered an extremely forceful speech in which he indicted the imperial regime, its origin, and its policy.

Press reports of his speech made his political fortune, and almost overnight Gambetta became an acknowledged leader of the Republican Party. In 1869 he was elected to the Legislative Assembly. He opposed the steps that led to the outbreak of the Franco-German War in July 1870, but, once it had begun, he urged the quickest possible victory over the Germans. After the disastrous defeat of the French at Sedan, in which Napoleon III was captured on Sept. 1, 1870, Gambetta played a principal role in proclaiming the republic and forming a provisional government of national defense. He became minister of the interior in this government.

The most pressing problem of the provisional government was the defense of Paris, which was besieged by the Germans. Most members of the government stayed in the city, but Gambetta, as their delegate, left Paris in a balloon on Oct. 17, 1870, floating over the German lines. Establishing himself at Tours, he began to arouse unoccupied France for the defense of the entire country. He became war minister as well, assuming virtually unlimited powers.

Of the two main French armies, one had been captured at Sedan, and the other was besieged at Metz and soon forced to surrender. Gambetta, as always enthusiastic and indefatigable, succeeded in raising new armies, which were trained and supplied with arms. These achieved some local successes but were more often defeated.

When Tours was threatened by the Germans, Gambetta left for Bordeaux in southwestern France. Though he wished to continue fighting, the country was tired of war, and the provisional government signed an armistice on Jan. 18, 1871.

The armistice convention provided for the election of a National Assembly, which met at Bordeaux in March 1871 to ratify the peace terms. Gambetta was elected a deputy for Strasbourg, in Alsace, but, after the ratification of the peace, which yielded most of Alsace and Lorraine to Germany, he lost his seat and retired for a short time to Spain.

In by-elections in July 1871, he was elected to the National Assembly by the *département* of the Seine. The assembly was to determine whether France would remain a republic or restore the monarchy. The majority of the deputies were monarchists. There were, however, two candidates to the throne, the heads, respectively, of the elder and the younger branch of the Bourbons, and they were unable to reach agreement on which should become king. With supreme skill, Gambetta managed to push ratification of the republic through the weary assembly. The republican constitution of 1875 formed the basis of the French Third Republic until the latter's demise in 1940.

Parliamentary intrigue prevented Gambetta from being elected president of the republic, but he became president of the Chamber of Deputies, a position in which he exercised great power. He attempted to promote a tolerant republic, an "Athenian republic," as he described it. In spite of his corpulence, disheveled beard, and badly groomed appearance, his natural warmth, generosity, and liberalism made him highly popular.

Jules Grévy, the president, disliked Gambetta and for a long time refused to ask him to form a government. After Gambetta at last was appointed premier in November 1881, he pursued, in foreign affairs, a policy of establishing a closer relationship with Great Britain and, in domestic affairs, an ambitious program of domestic reform. He was overthrown in January 1882 before achieving either goal.

In 1872 he began a liaison with Léonie Léon, a pretty, well-educated woman, and, after his resignation, he settled with her outside Paris, with the intention of marrying her. While handling a revolver, he shot himself in the arm, and, as his health was very poor, the wound healed slowly. During his convalescence, he was stricken with appendicitis, but the doctors did not operate. He died on Dec. 31, 1882, at the age of 44.

*Assessment.* Gambetta was honoured with a national funeral. His reputation has remained largely undiminished; there is hardly a town in France without a street bearing his name. Yet his fame rests on what he achieved in his long years of opposition and during the Franco-German War rather than during the two terms—totaling three years—in which he exercised power. He was a fervent advocate both of fully modern democracy—universal suffrage, freedom of the press, right of meeting, trial by jury for political offenses, separation of church and state—and of national unity. For the sake of the latter, he occasionally struck bargains with his political opponents, thus gaining an undeserved reputation as an opportunist. Undoubtedly, he was largely responsible for the consolidation of parliamentary democracy in France, but his compromises resulted in a fragile party system that served to weaken democratic government. (J.C. de C.)

**BIBLIOGRAPHY.** Biographical studies are combined with a history of the early Third Republic in Harold Stannard, *Gambetta and the Foundation of the Third Republic* (1921); and J.P.T. Bury, *Gambetta and the National Defense: A Republican Dictatorship in France* (1936, reprinted 1971), *Gambetta and the Making of the Third Republic* (1973), and *Gambetta's Final Years: 'The Era of Difficulties,' 1877–1882* (1982).

**Gambia, The**, officially REPUBLIC OF THE GAMBIA, republic of western Africa, covering an area of 4,127 square miles (10,689 square km). The capital is Banjul. Stretching inland 295 miles (475 km) eastward from the Atlantic Ocean, The Gambia is a narrow enclave (15 to 30 miles [24 to 48 km] wide)

The Gambia

along the Gambia River and on land is almost completely surrounded by Senegal. The population in 2000 was estimated at 1,367,000.

A brief treatment of The Gambia follows. For full treatment, see *MACROPAEDIA: Western Africa: The Gambia*.

For current history and for statistics on society and economy, see *BRITANNICA BOOK OF THE YEAR*.

**The land.** The Gambia River, which rises in Guinea and is navigable throughout The Gambia, dominates the country's landscape as it flows westward across a low plateau with elevations between 80 and 250 feet (25 and 75 m) above sea level. In the east, narrow valleys are separated by broad, low hills. In the west, lower and smaller sand hills alternate with depressions that often form sand-filled plains. The soils of the middle and upper river basin are more fertile than those of the lower river.

The climate is subtropical, with a marked hot and wet season (June to October) and a cooler dry season (November to April). Annual rainfall varies from 30 to 55 inches (760 to 1,400 mm) and comes only in summer. Annual temperatures range from 60° to 110° F (16° to 43° C), with daily temperatures exceeding 90° F (32° C) from April to June. The vegetation cover of The Gambia is savanna on the uplands, various kinds of inland swamp in low-lying areas, and mangrove swamp along the brackish lower Gambia River. The narrow strips of riverine forest shelter birds, but the large fauna—leopard, chimpanzee, west African manatee, western giant eland, and two species of crocodile—are found either in or beside the river itself or in the occasional dry savanna woodlands.

Only about one-sixth of the country is considered arable. It is generally poor in resources, but there are some reserves of zircon and kaolin.

**The people.** The country is populated by diverse ethnic groups. About one-third of the population is Malinke (Mandingo), followed by Fulani (about one-sixth), Wolof (about one-eighth), Diola (Jola), and Soninke (Serahuli). Most Gambians are Muslim. The population's birth and death rates and the rate of infant mortality are average for Western Africa but high by world standards, as is the average life expectancy, which is 53 years. The government has taken steps to develop a nationwide family-planning program. Farm labourers from Senegal, Guinea, and Mali seasonally increase The Gambia's population.

**Economy.** The Gambia has a developing market economy that is largely based on the production and export of peanuts (groundnuts). The gross national product (GNP) actually decreased somewhat during the 1980s and grew only marginally in the 1990s, causing the GNP per capita to fall during that period.

Agriculture accounts for nearly one-third of the GNP and employs more than three-fourths of the workforce, largely in subsistence-level farming. Food crops include rice, cassava, yams, sorghum, and millet. In an attempt to attain food self-sufficiency, the government encouraged the production of rice. Peanuts occupy almost all suitable land, and fluctuations in their production due to drought or pest infestations and in world peanut prices have tremendous impact on the country's economy.

Commercial fishing for both domestic and export markets has expanded. Further development of river fishing hinges on the construction of port and related facilities. Kaolin and zirconium are mined in the country in small quantities.

The industrial sector accounts for less than 5 percent of the GNP and employs an even smaller percentage of the workforce. Manufacturing is largely limited to food processing.

Electricity is generated entirely from imported fuels.

The Gambia River serves as a major artery of transportation, and all-weather road mileage has increased. Tourism has become an important source of revenue. The country's imports substantially outweigh its exports, and large-scale foreign aid is necessary to offset deficits in the balance of payments.

**Government and social conditions.** The Gambia is an independent republic with a constitution that went into effect in 1997. It provides for a 49-member National Assembly, which holds legislative power. The president, who is head of the government, is elected by universal suffrage to a five-year term. The vice president and cabinet members are appointed by the president from among the elected members of the assembly. The highest judicial body is the Supreme Court, and there are also Shari'ah courts, which hear cases on Islamic law.

The Gambia does not have a system of social-welfare benefits. Health conditions in The Gambia are extremely poor. A significant number of people suffer from such diseases as dysentery, malaria, schistosomiasis, and tuberculosis. Because of the country's severe shortage of trained medical personnel, many of the sick receive little or no medical care.

Education remains underdeveloped. Schooling is not compulsory, and only about one-third of all primary-school-age children are enrolled; more than three-fifths of the population is illiterate.

Most news media are owned by the government, and private media periodically are subject to harassment and retribution by the government.

**Cultural life.** The various tribal groups are the focus of cultural life in The Gambia. They engage in such activities as wood carving, batik cloth printing and weaving, and gold and silver jewelry making. The Ministry of Education, Sports, and Culture has encouraged the tribes to revive traditional dances.

**History.** The Wolof, Malinke, and Fulani (Fula, Fulbe) peoples, beginning in about the 13th century AD, settled in different parts of what is now The Gambia and established at first villages and then kingdoms in the region. European exploration of the area began when the Portuguese sighted the Gambia River in 1455. In 1588 the Portuguese sold trading rights on the river to British merchants, but no permanent settlements were established. In 1663 the British acquired a river island from a local chief and built Fort James there. In 1681 the French established an enclave at Albréda on the north bank opposite Fort James, and in 1779 they captured and destroyed that fort. Four years later the Treaty of Versailles reserved the Gambia River for Great Britain and recognized French claims to the enclave of Albréda. After the British abolished slavery in 1807, they founded the fort of Bathurst at the mouth of the Gambia River to block the continuing slave trade. In 1857 the French transferred sovereignty over Albréda to Britain, and in 1889 The Gambia's boundaries were agreed upon by Great Britain and France. The British declared a protectorate over the area in 1894. Independence was proclaimed in 1965, and The Gambia became a republic within the Commonwealth of Nations in 1970, with Sir Dawda Kairaba Jawara the country's first president. A 1981 coup attempt failed, and in the next year Jawara was reelected. Following the coup attempt, The Gambia and Senegal agreed to form a limited confederation called Senegambia, in which they would integrate their military and security forces, form an economic and monetary union, coordinate foreign policies and communications, and establish confederal institutions. The confederation dissolved in 1989, and in 1994 a coup brought a military gov-

ernment to power. Free elections were next held in 1997.

**Gambia River,** river in western Africa, 700 miles (1,120 km) long, rising in the Republic of Guinea and flowing westward through The Gambia into the Atlantic Ocean. Its major tributaries are the Sandougou and the Sofianiama. The Gambia is one of the finest waterways in Africa and the only western African river that is easily accessible to oceangoing shipping. It constitutes a unifying factor for the independent state of The Gambia, which consists of a narrow strip of land along both banks of the river. The political separation between The Gambia and Senegal has (despite a brief confederation between the two countries from 1982–89) long hindered the development of the resources of the river and its basin. A first step had been taken four years earlier, however, with the establishment of the Gambia River Development Organization, initially composed of the same two countries (joined in 1980 by Guinea).

From its source in the highlands of the Fouta Djallon, the Gambia follows a winding course to its mouth, which is a ria, or drowned estuary. The dividing and reuniting of river channels—a phenomenon known as braiding—has created several islands along the river's middle course, of which the two largest are Elephant Island and MacCarthy Island. The river is joined by numerous creeks called *bolons*, the largest of these being Bintang Bolon, which flows into it from the south. The width of the river's valley varies considerably along its course. The river valley is cut into a plateau of sandstone dating from the Tertiary period (66.4 million to 1.6 million years ago).

Dense mangrove swamps fringe the lower river for 60 miles (97 km) inland, after which freshwater swamps and salt flats on low-lying stretches alternate with dense clumps of small trees and shrubs that line the cliffs. On the higher slopes of the riverbank, swamps and shrubs give place to parkland and tall grass. The wild oil palm grows along the valley bottom.

The vegetation of the river and of its creeks provides a favourable habitat for insects, animals, and birds. The swamps encourage mosquitoes and tsetse flies to breed. The river abounds in fish and river creatures, including the hippopotamus and the crocodile. Among the 400 known bird species that have been recorded are the kingfisher, the cuckoo, the swallow, the heron, the sunbird, the hawk, and the grass warbler.

The swampy region closest to the river, with its dense masses of mangrove trees often growing more than 100 feet (30 m) high, abounds in wildlife but has been of little use for either agriculture or human settlement. The grass-covered river flats (known locally as *banto faros*) of the lower river are rendered useless for cultivation by the salt water that periodically inundates them, and settlements on them are few. The flats of the middle and upper river are of some agricultural value, however. Much of the grassland is regularly cleared, and the light soils are easily cultivable. The annual flooding of the fertile alluvial loams of the middle flats makes them especially suitable for intensive rice cultivation. On the light sandy and well-drained soils of the higher slopes, peanuts (groundnuts) grow particularly well. Cultivation and settlement have therefore taken place in the middle flats and on the higher slopes, with many villages being located on the borderline between the flats and the plateau, thus avoiding both the flooding of the lower slopes and the increasing aridity of the higher terrain.

The Gambia is one of the most navigable of

African rivers; its chief value, therefore, has been its transportation function. As the main artery of the state of The Gambia, it is the principal means of transporting passengers, freight, and mail in the territory. North-south river crossings are provided by ferries such as those plying between Barra and Banjul, Banni and Kerewan, Farafenni and Yelitenda, and Kau-ur and Jessadi.

**Gambier Islands**, French ÎLES GAMBIE, also called MANGAREVA ISLANDS, southeasternmost extension of the Tuamotu Archipelago of French Polynesia in the central South Pacific, nearly 1,000 miles (1,600 km) east-southeast of Tahiti. The principal inhabited group of the Gambiers comprises the volcanic islets Mangareva (Magareva), Taravai, Akamaru, and Aukena. Mangareva, which is 5 miles (8 km) long and encircled by a barrier reef, rises to approximately 1,444 feet (440 m) in the peaks Duff and Mokoto; Rikitea, the chief village, with St. Michael's Cathedral (1834-71), is on its eastern side.

Captain James Wilson of the missionary ship *Duff* sighted (1797) and named the Mangareva cluster for Admiral James Gambier. Annexed by the French in 1881, the group now forms a part of the Tuamotu-Gambier *circonscription* ("circumscription") of French Polynesia. The inhabitants support themselves with subsistence agriculture, coconuts, and a little fishing. Pop. (1988) 620.

**Gambino, Carlo** (b. Sept. 1, 1902, Palermo, Sicily, Italy—d. Oct. 15, 1976, Massapequa, N.Y., U.S.), head of one of the Five Families of organized crime in New York City from 1957 to 1976, with major interests in Brooklyn, and reputedly the "boss of bosses" of the U.S. national crime syndicate.

Born in Sicily, Gambino came to the United States in 1921 as a ship stowaway, settling in Brooklyn and becoming a gang member under, successively, Joe "the Boss" Masseria, Salvatore Maranzano, Philip and Vincent Mangano, and finally (in 1951) Albert Anastasia. When Anastasia was murdered in 1957 (allegedly by Gambino and another gunman and with Vito Genovese's approval), Gambino inherited leadership of the family, whose operations included gambling, loansharking, hijacking, narcotics trafficking, and, notably, labour racketeering, with extensive controls over waterfront unions.

In 50 years of crime Gambino served only 22 months in prison (1937-38). Although he was indicted in 1970 for hijacking and although the U.S. Supreme Court in 1970 also upheld an order for his deportation (because of illegal entry into the country), severe heart attacks deferred trial or deportation. More heart seizures led to his death by natural causes six years later.

**Gamblian Pluvial Stage**, major division of Pleistocene rocks and time in Africa (the Pleistocene Epoch began about 1,600,000 years ago and ended about 10,000 years ago). The Gamblian Pluvial, a moist period that began about 30,000 years ago and lasted about 20,000 years, followed the Kanjeran Pluvial Stage and preceded the Makalian Wet Phase, from each of which it was separated by a period of drier conditions. The Gamblian has been equated in time with the major portion of the Würm Glacial Stage of Europe. Three phases of the Gamblian have been recognized in depositional features along prominent lakeshores. Dates for the various phases of the stage are well established on the basis of radiometric techniques. During the Gamblian, eastern Africa was the scene of prominent Earth movements.

**gambling**, the betting or staking of something of value, with consciousness of risk and hope

of gain, on the outcome of a game, a contest, or an uncertain event whose result may be determined by chance or accident or have an unexpected result by reason of the bettor's miscalculation.

Gambling games may vary in complexity from betting on the outcome of the toss of a coin, in which the winner claims the coin the side of which he correctly guesses, to betting on cards dealt in a game such as poker, in which strategy also applies. The outcomes of gambling games may be determined by chance alone, as in the purely random activity of a tossed pair of dice or of the ivory ball on a roulette wheel, or by physical skill, training, or prowess in athletic contests, or, again, by a combination of strategy and chance. The rules by which gambling games are played sometimes serve to confuse the relationship between the components of the game, which depend on skill and chance, so that some players may be able to manipulate the game to serve their own interests. Thus, knowledge of the game is useful to the poker player or the horse-race gambler but is of very little use to the purchaser of a lottery ticket or to a slot-machine player.

A gambler may participate in the game itself while betting on its outcome (card games, craps), or he may be prevented from any active participation in an event in which he has a stake (professional athletics, lotteries). Some games are dull or nearly meaningless without the accompanying betting activity and are rarely played unless wagering occurs (coin tossing, poker, dice games, lotteries). In other games, betting is not intrinsically part of the game, and the association is merely conventional and not necessary to the performance of the game itself (horse racing, football pools). Commercial establishments such as casinos and racetracks may organize gambling when a portion of the money wagered by patrons can be easily acquired by participation as a favoured party in the game, by rental of space, or by withdrawing a portion of the betting pool. Some activities of very large scale (horse racing, lotteries) usually require commercial and professional organizations to present and maintain them efficiently.

*Prevalence of principal forms.* Betting on the result of a horse race is a leading form of gambling in the English-speaking countries and in France. It also exists in Argentina, Colombia, Mexico, Puerto Rico, Venezuela, Indonesia, Japan, the Philippines, Denmark, Germany, Ireland, Italy, Norway, Sweden, Poland, and many other countries. Wherever horse racing is popular, it has usually become a major business, with its own newspapers and other periodicals; extensive statistical services; self-styled experts who sell advice on how to bet; sophisticated communication networks that furnish information to betting centres; bookmakers and their employees; and workers incidental to the care and breeding of horses. The same is true, to a smaller extent, of dog racing. The emergence of satellite broadcasting technology has led to the creation of so-called off-track betting facilities, in which bettors watch live telecasts at locations away from the racetrack.

Casinos or gambling houses—places where gamblers can risk their money against a common gambler, called the bank, or the house—have existed at least since the 17th century. In the 20th century they became commonplace and assumed almost a uniform character throughout the world. In Europe and South America they are permitted at many or most holiday resorts but rarely in cities. In the United States casinos were for many years legal only in Nevada and New Jersey and, by special license, in Puerto Rico, but many other states now allow casino gambling, and betting facilities operate illegally, through corruption of political authorities, throughout the country. Among the games played reg-

ularly at casinos, roulette, which is one of the principal gambling games in France and Monaco, is played throughout the world. Crap shooting is the principal game at most American casinos. Slot machines are a mainstay of casinos in the United States and also are found in thousands of private clubs, restaurants, and other establishments; they are common in other countries, including Australia, where they are known as poker machines, and in Great Britain, where they are called fruit machines. Among the card games played at casinos, baccarat, in its popular form chemin de fer, has remained a principal gambling game in Great Britain and in the continental casinos most often patronized by the English at Deauville, Biarritz, and the Riviera resorts. Faro, at one time the principal gambling game in the United States, has, since the ascendancy of craps, become almost obsolete. Poker is offered at many establishments, but blackjack is the principal card game in American casinos. The French card game trente et quarante (or rouge et noire) is played at Monte Carlo and other continental casinos.

State-licensed or state-operated lotteries expanded rapidly in the United States during the late 20th century and are widely distributed throughout most of the world. Soccer-pool companies can be found in Great Britain, Sweden, Australia, and a few African nations.

*Chances, probabilities, and odds.* Events or outcomes that are equally probable have an equal chance of occurring in each instance. In games of pure chance, each instance is a completely independent one; that is, each play has the same probability as each of the others of producing a given outcome. Probability statements apply in practice to a long series of events but not to individual ones. The "law of large numbers" is an expression of the fact that the ratios predicted by probability statements are increasingly accurate as the number of events increases; but the absolute number of outcomes of a particular type departs from expectation with increasing frequency as the number of repetitions increases. It is the ratios that are accurately predictable, not the individual events or precise totals.

The probability of a favourable outcome among all possibilities can be expressed: probability ( $p$ ) equals the total number of favourable outcomes ( $f$ ) divided by the total number of possibilities ( $t$ ), or  $p = f/t$ . But this holds only in situations governed by chance alone. In a game of tossing two dice, for example, the total number of possible outcomes is 36 (each of six sides of one die combined with each of six sides of the other), and the number of "ways to make," say, a seven are six (made by throwing 1 and 6, 2 and 5, 3 and 4, 4 and 3, 5 and 2, or 6 and 1); therefore, the probability of throwing a seven is 6/36, or 1/6 (or approximately .167).

In most gambling games it is customary to express the idea of probability in terms of "odds against winning." This is simply the ratio of the unfavourable possibilities to the favourable ones. If the probability of throwing a seven is 1/6, then in every six throws, "on the average," one throw would be favourable and five would not; the odds against throwing a seven are therefore 5 to 1. The probability of getting "heads" in a toss of a coin is one-half; the odds are 1 to 1, called "even." Care must be used in interpreting the phrase "on the average." Again it applies most accurately to a large number of cases and is not useful in individual instances. A common gamblers' fallacy called "the doctrine of the maturity of the chances" (or "Monte Carlo fallacy") falsely assumes that each play in a game of chance is not independent of the others and that a series of outcomes of one sort should be balanced in the short run by the other possibilities. A number of "systems" have been invented by gamblers based largely on this fallacy; casino operators are happy to encourage the use of

such systems and to exploit any gambler's neglect of the strict rules of probability and independent plays.

In some games an advantage may go to the dealer, banker (the individual who collects and redistributes the stakes), or some other participant. Therefore, not all players have equal chances to win or equal payoffs. This inequality may be corrected by rotating the players among the positions in the game. Commercial gambling operators, however, usually make their profits by regularly occupying advantaged positions; or they may charge money for the opportunity to play or subtract a proportion of money from the bank on each play. In the dice game of Craps the casino returns to winners from  $\frac{3}{5}$  of 1 percent to 27 percent less than the correct odds, depending on the type of bet made. The house percentage in Roulette in American casinos is  $5\frac{3}{19}$  percent to  $7\frac{17}{19}$  percent, and in European casinos it is  $1\frac{13}{37}$  percent to  $2\frac{26}{37}$  percent. The house must always win in the long run. Some casinos also add rules that enhance their profits, especially rules that limit the amounts that may be staked under certain circumstances.

Many gambling games include elements of physical skill or strategy as well as of chance. The game of Poker, like most other card games, is a mixture of chance and strategy. Betting on horse racing or athletic contests involves the assessment of a contestant's physical capacity and the use of other evaluative skills. In order to assure that chance is allowed to play a major role in determining the outcomes of such games, weights, handicaps, or other correctives may be introduced in certain cases to give the contestants approximately equal opportunities to win, and adjustments may be made in the payoffs so that the probabilities of success and the magnitudes of the payoffs are put in inverse proportion to each other. Pari-mutuel pools in horse-race betting, for example, reflect the chances of various horses to win as anticipated by the players. The individual payoffs are large for those bettors whose winning horses are backed by relatively few bettors and small if the winners are backed by a relatively large proportion of the bettors; the more popular the choice, the lower the individual payoff. The same holds true for betting with bookmakers on athletic contests (illegal in most of the United States but legal in England). Bookmakers ordinarily accept bets on the outcome of what is regarded as an uneven match by requiring the side more likely to win to score more than a simple majority of points. In a game of United States or Canadian football, for example, the more highly regarded team would have to win by, say, more than 10 points to yield an even payoff to its backers.

Unhappily, these procedures for maintaining the influence of chance can be interfered with; cheating is possible and reasonably easy in most gambling games. Much of the stigma attached to gambling has resulted from the dishonesty of its promoters, and a large proportion of modern gambling legislation is written to control cheating. More laws have been oriented, however, to efforts by governments to derive tax revenues from gambling than to control cheating. (Taxes can be levied against the incomes of the promoters or players or of the turnover [bank, pool] itself.)

**gamboge**, also spelled CAMBOGE, hard, brittle gum resin that is obtained from various Southeast Asian trees of the genus *Garcinia* and is used as a colour vehicle and in medicine. Gamboge is orange to brown in colour and when powdered turns bright yellow. Artists use it as a pigment and as a colouring matter for varnishes. In medicine and veterinary medicine it is a drastic cathartic. On the skin it has a severe irritant effect. Gamboge was probably brought into Europe from the East at the close of the 16th century.

Gamboge is obtained principally from *G. hanburyi*, a dioecious tree with leathery, laurel-like leaves, small yellow flowers, and usually square-shaped, four-seeded fruit; it is indigenous to Cambodia and parts of Thailand and southern Vietnam. The tree's juice in its hardened form constitutes gamboge. The juice is contained in ducts in the middle layer of the bark and is procured by making incisions in the bark and then collecting the juice as it exudes.

**Gamburtsev Mountains**, Russian GORY GAMBURTSEVA, subglacial range in the central part of eastern Antarctica, extending 750–800 miles (1,200–1,300 km). The mountains attain their greatest height at 11,120 feet (3,390 m). Completely buried under more than 1,970 feet (600 m) of the Antarctic ice cap, they were discovered in 1958 by a Soviet expedition and mapped by seismic reflections.

**game**, a universal form of recreation generally including any activity engaged in for diversion or amusement and often establishing a situation that involves a contest or rivalry. Card games are the games most commonly played by adults. Children's games include a wide variety of amusements and pastimes primarily for children. See also card game; children's game; sports and games.

**game**, in gastronomy, the flesh of any wild animal or bird. Game is usually classified according to three categories: (1) small birds, such as the thrush and quail; (2) game proper, a category that can be subdivided into winged game, such as the goose, duck, woodcock, grouse or partridge, and pheasant; and ground game, such as the squirrel, hare, and rabbit; (3) big game, predominantly venison, including roebuck, deer, elk, moose, and caribou but also including other large animals such as bear and wild boar.

In general, game is drawn and allowed to cool after being killed and then hung for several days. Whether or not game birds should be drawn is a debated issue. A common practice is not to draw birds with slender, tapering beaks, such as the thrush or corncrake.

The meat of young game is generally easily digested. Small birds, usually eaten within a short time after the kill, are considered to be as digestible as poultry. Ground game, which is classed among red meats, is usually readily digestible, but some such meat, like that from hare, may be rich in elements that make it more resistant to digestion than domestic meat acquired from a butcher. Meat from older game, or from an animal exhausted in the chase, is less desirable, but it can be improved by marinating it for several hours, usually in a mixture of wine, vinegar, and spices.

While most game is cooked in simple country fashion, this class of foods has given rise to numerous renowned, sometimes very elaborate gourmet dishes. Young boar, or wild pig, that has been roasted, grilled, braised, or smoked is considered a delicacy, as is pheasant. Bear steak was a popular dish among North American trappers; as served today in wilderness lodges and urban restaurants, it is usually prepared like beef, except that it is marinated for a few days prior to cooking. A favourite dish in Russia is braised bear, served with sour cream.

Hare and rabbit are among the most widely eaten game. Young hare is usually roasted, and older hare is made into pâtés and pies, potted, jugged, and casserole. Rabbit can be stuffed with bread and herbs before baking, potted with layers of bacon or ham, and stewed with vegetables.

**game show**: see quiz show.

**game theory**, branch of mathematics used to analyze competitive situations whose outcomes depend not only on one's own choices, and perhaps chance, but also on the choices

made by other parties, or "players." Since the outcome of a game is dependent on what all players do, each player tries to anticipate the probable choices of other players in order to determine his own best choice. How these interdependent strategic calculations may reasonably be made is the subject of the theory.

A brief treatment of game theory follows. For full treatment, see MACROPAEDIA: Game Theory.

Modern game theory was created practically at one stroke by the publication in 1944 of *Theory of Games and Economic Behavior* by the mathematician John von Neumann and the economist Oskar Morgenstern. This book stimulated rapid, worldwide development of the mathematical theory and its applications to economics, politics, military science, operations research, business, law, sports, biology, and other fields. It has had a major influence, widening and refining common discourse on strategic thinking.

The theory has several major divisions, the following being the most important:

**Two-person versus *n*-person**. The 2-person theory deals with the optimal strategic choices of two players, whereas the *n*-person theory ( $n > 2$ ) mostly concerns what coalitions, or subsets of players, will form and be stable and what constitute reasonable payments to their members.

**Zero-sum versus nonzero-sum**. The payoffs to all players add up to zero (or some other constant) at each outcome in zero-sum games but not in nonzero-sum games, wherein the sums are variable; zero-sum games are games of total conflict, in which what one player gains the others lose, whereas nonzero-sum games permit the players to gain or lose simultaneously.

**Cooperative versus noncooperative**. Cooperative games are those in which players can make binding and enforceable agreements, whereas noncooperative games may or may not allow for communication among the players but always assume that any agreement reached leads to equilibrium—that is, it is rational for a player not to violate it if other players do not.

Common to all areas of game theory is the assumption that players are rational in the sense that they prefer better over worse outcomes; it is also assumed that they have goals and can rank-order the outcomes or, more stringently, attach utilities, or values, to them. Complications arise from the fact that, except in degenerate one-person games, which are sometimes called "games against nature" and are the subject of decision theory, there is generally no straightforward best choice for a player because of the inherent interdependency of the various choices in a game.

**gamelan**, also spelled GAMELANG, or GAMELIN, the indigenous orchestra of Java and Bali, consisting largely of several varieties of gongs and various sets of tuned instruments that are struck with mallets. The gongs

Indonesian gamelan  
By courtesy of the Indonesian Tourist Board

are either suspended vertically or, as with the knobbed-centre, kettle-shaped bonang, placed flat. Percussive melodic instruments include sets of tuned bonangs, xylophones (the *gambang kayu*), and metallophones (these are instruments with a series of tuned metal plates, either suspended over a resonance trough or on resonance tubes). A sustained melody is played either by the bamboo flute (the *suling*) or by a bowed string instrument (rebab) or is sung—the last especially when, as often occurs, the gamelan is used to accompany theatrical performances, or wayangs. The voice is then part of the orchestral texture. Dominating these two groups of instruments is the drum (the *kendang*), which unites them and acts as leader.

No two gamelans are precisely alike tonally, for each instrument is tuned only to the gamelan for which it is intended rather than to an external standard of pitch. A gamelan typically consists of two sets of instruments, one tuned to the scale of *slendro* (in which the octave is divided into five tones roughly equidistant) and the other to *pelog* (a scale consisting of seven notes of varying intervals of which five are given principal stress). The modes (*patet*) of gamelan music are determined by the relative placement on either scale of the basic note (*dong*) and its fifth above and fifth below. (A fifth is an interval more or less the size of that formed by five adjacent white keys on a piano.)

The highly developed polyphony (multipart music) or heterophony (music in which one part varies a melody played simultaneously in another part) of the gamelan has a rhythmic origin. A nuclear theme extends over a number of "bars" (almost invariably in  $\frac{4}{4}$  time), against which other instruments play a largely independent countermelody. Another group plays rhythmic paraphrases of this theme, and a fourth group fills out the texture with delicate rhythmic patterns. Highly important are the punctuating, or colotomic, instruments that divide the musical sentence, marking, as it were, the commas, semicolons, and periods. This last-named function is done with the big gong. Over this shimmering, variegated pattern of hammered sound floats the uninterrupted melodic line of the voice, the flute, or the rebab.

**Gamelin, Maurice(-Gustave)** (b. Sept. 20, 1872, Paris, Fr.—d. April 18, 1958, Paris), French army commander in chief at the beginning of World War II who proved unable to stop the German assault on France (May 1940) that led to the French collapse in June of that year.

Gamelin graduated from the Saint-Cyr military academy in 1893 and ended World War I as a brigadier general in command of a division. He rose steadily after the war, becoming army chief of staff in 1931 and president of the Supreme War Council and army inspector in 1935. He was appointed chief of staff of the national defense in 1938.

Gamelin

By courtesy of the Bibliothèque Nationale, Paris

Gamelin was a strong supporter of the defensive strategy based on the Maginot Line, and, as commander of Allied forces in the West when World War II broke out, he took no offensive action even though at that time most of the German forces were engaged in Poland. In the "phony war" that followed, he proved similarly prudent and unaggressive. He was taken by surprise by the German offensive through the Ardennes that cut the Allied front in two in May 1940. He was dismissed on May 19 and replaced by General Maxime Weygand. Gamelin was later placed on trial at Riom by the Vichy government and, from 1943, was interned in Germany until the end of the war. His memoirs, *Servir*, 3 vol. (*Servir*), appeared in 1946–47.

**Gamelyn, The Tale of**, anonymous English metrical romance of about 1350, some 900 lines long, written in the East Midland dialect of Middle English, in rhymed couplets. Based on English folklore, it tells of Gamelyn, son of Sir John de Boundys, who is deprived of his inheritance by his brother and becomes an outlaw in the forest. Eventually he is able to regain his estates, and the sheriff who had helped his brother is hanged.

*The Tale of Gamelyn* is of special interest for its connections with the English ballads of the outlaw Robin Hood. It was a source of Thomas Lodge's prose romance *Rosalynde* (1590), on which William Shakespeare based his *As You Like It*. It was almost certainly intended by Geoffrey Chaucer to form the basis of his (unfinished) "Cook's Tale" in *The Canterbury Tales*.

**gamete**, sex, or reproductive, cell containing only one set of dissimilar chromosomes, or half of the genetic material necessary to form a complete organism (*i.e.*, haploid). During fertilization, male and female gametes fuse, producing a diploid (*i.e.*, containing paired chromosomes) zygote. Gametes may be identical in form (isogamy), as in the black mold (*Rhizopus*), or there may be more than one morphological type (heterogamy), as with many green algae of the genus *Chlamydomonas*. Gametes of animals, some algae and fungi, and all higher plants exhibit an advanced form of heterogamy called oogamy. In oogamy, one of the gametes is small and motile (the sperm), and the other is large and nonmotile (the egg). *See also* sperm.

**gametophyte**, in certain plants, sexual phase (or an individual representing the phase) in the alternation of generations—a phenomenon in which two distinct phases occur in the life history of the plant, each phase producing the other. The alternate, nonsexual phase is the sporophyte.

In the gametophyte phase, male and female organs (gametangia) develop and produce eggs and sperm (gametes), which unite in fertilization (syngamy). The fertilized egg (zygote) develops into the sporophyte phase, which produces numerous unicellular spores. These, in turn, develop directly into new gametes. Almost the entire life cycle of many algae and fungi is gametophyte; in others it is almost all sporophyte. *See also* sporophyte.

**gamma decay**, type of radioactivity in which some unstable atomic nuclei dissipate excess energy by a spontaneous electromagnetic process. In the most common form of gamma decay, known as gamma emission, gamma rays (photons, or packets of electromagnetic energy, of extremely short wavelength) are radiated. Gamma decay also includes two other electromagnetic processes, internal conversion and internal pair production. In internal conversion, excess energy in a nucleus is directly transferred to one of its own orbiting electrons, thereby ejecting the electron from the atom. In internal pair production, excess energy is directly converted within the electromagnetic field of a nucleus into an electron

and a positron (positively charged electron) that are emitted together. Internal conversion always accompanies the predominant process of gamma emission to some extent. Some nuclei of a sample decay by gamma emission, others by internal conversion. Internal pair production requires that the excess energy of the unstable nucleus be at least equivalent to the combined masses of an electron and a positron (that is, in excess of 1,020,000 electron volts).

The unstable nuclei that undergo gamma decay are the products either of other types of radioactivity (alpha and beta decay) or of some other nuclear process, such as neutron capture in a nuclear reactor. These product nuclei have more than their normal energy, which they lose in discrete amounts as gamma-ray photons until they reach their lowest energy level, or ground state.

Typical half-lives for gamma emission are immeasurably short (from about  $10^{-9}$  to  $10^{-14}$  second). When the half-lives for gamma emission are measurable, the nucleus in the higher energy state before radiating a photon and the one in the lower energy state are called nuclear isomers. *See also* isomer.

**gamma function**, generalization of the factorial function to nonintegral values. (The factorial is written as  $n!$ , with  $n!$  defined as the product  $1 \times 2 \times 3 \times \dots \times n$ ). If a graph is drawn (*see* graph) of the function  $y = x!$  when  $x = 0, 1, 2, 3, \dots$  etc., the points can be joined by a curve, and the gamma function gives a precise way of defining and calculating these intermediate points on the curve. The gamma function  $\Gamma(z)$  can be defined as the value that is approached by the quo-

Gamma function

tient  $n!n^z / (z+1)(z+2)\dots(z+n)$  as  $n$  gets larger and larger, and is equivalent to its definition as a type of infinite sum given by an integral. For  $z = 1$ , this integral equals 1, and an operation with integrals known as integration by parts gives the recursion relation  $\Gamma(z+1) = z\Gamma(z)$ . Using these two facts together,  $\Gamma(2) = 1\Gamma(1) = 1$ ,  $\Gamma(3) = 2\Gamma(2) = 2$ , etc., can be calculated, giving the result that  $\Gamma(n) = (n-1)!$  when  $n$  is an integer.

The gamma function is useful more for its relationship to other functions than as a solution by itself of some problem. It arises in simplifying the evaluation of some infinite or improper integrals and in the solution of differential and difference equations arising in probability theory, statistics, mathematical physics, and engineering mathematics.

**gamma globulin**, subgroup of the blood proteins called globulins. In humans and many of the other mammals, antibodies, when they are formed, occur in the gamma globulins. Persons who lack gamma globulin or who have

an inadequate supply of it—conditions called, respectively, agammaglobulinemia and hypogammaglobulinemia—have frequently recurring infections because of their inability to develop adequate immunity to infectious diseases. *See also* antibody.

**gamma ray**, penetrating electromagnetic radiation of the same nature as an X ray, though usually of somewhat shorter wavelength, emitted spontaneously by some radioactive substances.

Gamma rays were named (1903) by Ernest Rutherford when evidence showed they differed from beta rays (electrons ejected by radioactive nuclei). Gamma radiation originates in atomic nuclei during radioactive decay, sometimes in the decay of certain subatomic particles (as pions and sigma particles), and in particle-antiparticle annihilation. The absorption of gamma rays by nuclei can cause particles (as neutrons, alpha particles) to be ejected (photodisintegration) or can even split the nucleus (photofission). A high-energy gamma photon passing near a nucleus sometimes produces a pair of electrons, one negative (negatron), the other positive (positron). Gamma-ray photons lose energy by being scattered from free electrons (Compton effect) or are completely absorbed by ejecting electrons from atoms (photoelectric effect).

**gammarid**, any member of the family Gammaridae, the largest of 80 or so families that make up the crustacean order Amphipoda. The name is sometimes also used to refer to amphipods of the genus *Gammarus*. The body of a gammarid is of basic amphipod shape: it is flattened from side to side, with seven pairs of thoracic walking legs (the first two pairs often enlarged) and six pairs of abdominal limbs, of which the front three pairs are used for swimming and the back three for gliding locomotion on solid surfaces. Gammarids grow to about 5 to 30 mm (0.2 to 1.2 inches) long. About 250 species are known. They occur exclusively in the Northern Hemisphere, primarily in freshwater bodies. Gammarids may be locally abundant among aquatic plant growth, feeding largely on fragmented organic matter. Eggs and young develop in a ventral brood pouch.

**Gammexane**, trade name for an insecticide composed of the most toxic of the isomeric forms of benzene hexachloride (*q.v.*).

**Gamow, George**, original Russian GEORGY ANTONOVICH GAMOV (b. March 4, 1904, Odessa, Russian Empire [now in Ukraine]—d. Aug. 19, 1968, Boulder, Colo., U.S.), Russian-born American nuclear physicist and cosmologist who was one of the foremost advocates of the big-bang theory, according to which the universe was formed in a colossal explosion that took place billions of years ago. In addition, his work on deoxyribonucleic acid (DNA) made a basic contribution to modern genetic theory.

Gamow attended Leningrad (now St. Petersburg) University, where he studied briefly with A.A. Friedmann, a mathematician and cosmologist who suggested that the universe should be expanding. At that time Gamow did not pursue Friedmann's suggestion, preferring instead to delve into quantum theory. After graduating in 1928, he traveled to Göttingen, where he developed his quantum theory of radioactivity, the first successful explanation of the behaviour of radioactive elements, some of which decay in seconds while others decay over thousands of years.

His achievement earned him a fellowship at the Copenhagen Institute of Theoretical Physics (1928–29), where he continued his investigations in theoretical nuclear physics. There he proposed his "liquid drop" model of atomic nuclei, which served as the basis for the modern theories of nuclear fission and fusion. He also collaborated with F. Houter-

mans and R. Atkinson in developing a theory of the rates of thermonuclear reactions inside stars.

In 1934, after emigrating from the Soviet Union, Gamow was appointed professor of physics at George Washington University in Washington, D.C. There he collaborated with Edward Teller in developing a theory of beta decay (1936), a nuclear decay process in which an electron is emitted.

Soon after, Gamow resumed his study of the relations between small-scale nuclear processes and cosmology. He used his knowledge of nuclear reactions to interpret stellar evolution, collaborating with Teller on a theory of the internal structures of red giant stars (1942). From his work on stellar evolution, Gamow postulated that the Sun's energy results from thermonuclear processes.

Gamow and Teller were both proponents of the expanding-universe theory that had been advanced by Friedmann, Edwin Hubble, and Georges LeMaitre. Gamow, however, modified the theory and named his version the "big bang." He and Ralph Alpher published this theory in a paper called "The Origin of Chemical Elements" (1948). This paper, attempting to explain the distribution of chemical elements throughout the universe, posits a primeval thermonuclear explosion, the big bang that began the universe. According to the theory, after the big bang, atomic nuclei were built up by the successive capture of neutrons by the initially formed pairs and triplets.

In 1954 Gamow's scientific interests grew to encompass biochemistry. He proposed the concept of a genetic code and maintained that the code was determined by the order of recurring triplets of nucleotides, the basic components of DNA. His proposal was vindicated during the rapid development of genetic theory that followed.

Gamow held the position of professor of physics at the University of Colorado, Boulder, from 1956 until his death. He is perhaps best known for his popular writings, designed to introduce to the nonspecialist such difficult subjects as relativity and cosmology. His first such work, *Mr. Tomkins in Wonderland* (1936), gave rise to the multivolume "Mr. Tomkins" series (1939–67). Among his other writings are *One, Two, Three . . . Infinity* (1947), *The Creation of the Universe* (1952; rev. ed., 1961), *A Planet Called Earth* (1963), and *A Star Called the Sun* (1964).

**gamut**, in music, the full range of pitches in a musical system; also, the compass of a particular instrument or voice. The word originated with the medieval monk Guido of Arezzo (d. 1050) to identify his system of solmization, *i.e.*, of using syllables to denote musical tones in a scale. Thus, to render in syllables the six tones of the hexatonic scale that prevailed, Guido started with the lowest tone recognized in medieval music theory, the second G below middle C, or gamma. For this note he selected the syllable *ut* from the hymn "Ut queant laxis" and for the ascending tones used the syllables *re*, *mi*, *fa*, *sol*, and *la*. Since Guido and his successors conceived musical theory in terms of overlapping hexachords rather than the diatonic scale, the syllable *ut* could represent any of the three pitches capable of sustaining the overlapping hexachords that made up the system; these were C, F, and G. While *ut* might vary, there was only one gamma-*ut*.

Gradually, the word's meaning was extended to include the whole range from gamma-*ut* to the high E and contracted to gamut. After diatonic scales displaced the system of overlapping hexachords, gamut came to designate any maximal scale within reach of a given instrument or voice, hence the literary phrase "ranging over the whole gamut of human emotions." *See also* hexachord; solmization.

**Gan** (people): *see* Ga.

**Gan Jiang** (China): *see* Kan River.

**Gana, Alberto Blest**: *see* Blest Gana, Alberto.

**Gaṇapati** (Hindu god): *see* Gaṇeśa.

**Gaṇapatya**, member of an esoteric Hindu sect devoted to the worship of the elephant-headed Gaṇeśa (also called Gaṇapati) as the supreme deity. The sect was at its height in about the 10th century and helped to establish Gaṇeśa as an important minor deity to be propitiated at the beginning of all important undertakings and religious ceremonies. The sect erected temples dedicated to Gaṇeśa, the largest of which is the Ucchi-pillaiyar Kovil, a rock-cut temple near Tiruchchirappalli in Tamil Nadu state.

Gaṇeśa was worshiped both by meditating upon his image and by offering him fruit and flowers without meditation. Sect members wore a red circle on their foreheads and branded themselves on the shoulders with the mark of an elephant's face and tusk.

**Ganassa, Zan**, pseudonym of ALBERTO NASELLI, Naselli also spelled NASELI (b. 1540?—d. 1584?), one of the most important and influential actors and company managers of the early Italian commedia dell'arte.

Ganassa, who took his name from that of a character he invented, was perhaps the first to take a commedia company beyond the borders of Italy. Evidence exists of his appearances at Mantua (1568) and Ferrara (1570), and a performance by him and his company in Paris in 1571 was perhaps the first of an Italian troupe in that capital. The company appeared in France several times during the next three years, most notably in 1572, when they were invited by Charles IX to entertain at the wedding of his sister, Margaret of Valois, to Henry of Navarre.

By 1574 Ganassa and his troupe were performing in Madrid, beginning a decade's work in Spain and making one of the first appearances there by a commedia troupe. The company eventually acted in at least four theatres in Madrid, as well as in theatres at Seville, Valladolid, Guadalajara, and Toledo. The influences of Ganassa and his company upon the nascent Spanish professional theatre were many: the business organization of the commedia troupe was adopted by the Spanish; the *corrales* (theatres) being constructed at this time were altered to accommodate the practice of the Italians; and the new secular drama, especially the plays of Lope de Vega, frequently reflected the characters and situations that were the stock of the foreigners.

**Găncă**, also spelled GĂNĬĂ, GANDZHA, GJANDZHA, or GYANDZHA, formerly (1935–89) KIROVABAD, or (1804–1918) YELIZAVETPOL, city, western Azerbaijan. It lies along the Găncă River. The town was founded sometime in the 5th or 6th century, about 4 miles (6.5 km) east of the modern city. That town was destroyed by earthquake in 1139 and rebuilt on the present site. Găncă became an important centre of trade, but in 1231 it was again leveled, this time by the Mongols. Captured in 1606 by the Persians, it became the centre of the Găncă khanate. In 1804 Găncă was annexed by the Russians and renamed Yelizavetpol. It was made a provincial seat in 1861 and in 1935 was renamed Kirovabad. Kirovabad developed industrially and became one of the largest cities of Azerbaijan. The city's original name was restored in 1989.

Alumina was made from local alunite in Găncă, using power from hydroelectric plants on the Găncă and Kura rivers, but is now manufactured from imported bauxite. The city also manufactures machinery and instruments. Situated at the centre of a rich

farming area, it processes agricultural products and makes cotton textiles and carpets. Gāncā has agricultural and teacher-training

The Dzhuma-Mechet Mosque, 17th century, in Gāncā, Azerbaijan  
Novosti Press Agency

institutes. Notable buildings include Dzhuma-Mechet Mosque (built 1620) and the modern mausoleum of the 12th-century Persian poet Neẓāmī Ganjavī. Pop. (1991 est.) 282,200.

**Gance, Abel** (b. Oct. 25, 1889, Paris, France—d. Nov. 10, 1981, Paris), important director in the post-World War I revival of the French cinema who is best known for extravagant historical spectacles.

Working in the cinema from 1909, Gance first gained recognition with his films *Mater dolorosa* (1917; "Sorrowful Mother," remade in 1932) and *La Dixième Symphonie* (1918; "Tenth Symphony"). Influenced by the epic style of the pioneer American director D.W. Griffith, he earned a reputation for grand-scale dramas such as *J'accuse!* (1918; "I Accuse!," remade in 1937), a 14-reel antiwar statement, and *La Roue* (1922; "The Wheel"), a film about railway workers and the mechanization of modern life that was consciously composed to a definite rhythmic pattern.

*Napoléon vu par Abel Gance* (1927; "Napoleon as Seen by Abel Gance," rereleased and revised in 1934, 1971, and 1979), his best-known film, was a monumental four-year undertaking in which he used experimental techniques such as superimposition, hand-coloured film, and rapid cutting to emphasize cinematic movement; it included sweeping battle sequences filmed with three separate cameras. When the film appeared in theatres,

Gance, 1954  
H. Roger-Viollet

three projectors showed separate views of certain vital scenes on three connecting screens. This Polyvision technique was a precursor of Cinerama, the wide-screen process using synchronized projectors, popularized during the 1950s. Gance also pioneered in the use of stereophonic sound. Another of his ambitious films was *Un Grand Amour de Beethoven* (1936; *The Life and Loves of Beethoven*). His later films, mainly period adventures, included *La Tour de Nesle* (1954; "The Tower of Nesle"), *Austerlitz* (1960; *The Battle of Austerlitz*), and *Cyrano et d'Artagnan* (1963).

**Ganda**, also called BAGANDA, or WAGANDA, people inhabiting the area north and northwest of Lake Victoria in south-central Uganda. They speak a Bantu language—called Ganda, or Luganda—of the Benue-Congo group. The Ganda are the most numerous people in Uganda and their territory the most productive and fertile. Once the core of the Uganda Protectorate, they have a higher standard of living and are more literate and modernized than any other people in Uganda.

The traditional Ganda are settled hoe cultivators, with plantains their staple food. They also grow cotton and coffee for export. They keep sheep, goats, chickens, and cattle.

Descent, inheritance, and succession are patrilineal. About 50 exogamous clans are recognized, each having principal and secondary totem animals that may not be killed or eaten.

Traditional Ganda religion recognized ancestors, past kings, nature spirits, and a pantheon of gods who were approached through spirit mediums. Most modern Ganda, however, are Christian. Traditional Ganda villages were compact, centred on the chief's house.

By the early 19th century the Ganda had developed a well-organized, efficient administrative hierarchy and a sophisticated political system centred on the institution and person of the kabaka (king). The kabaka was also the high priest and supreme judge of the land. Ruling through a system of governors and district chiefs, the kabaka maintained absolute control over his ever-expanding kingdom. The Ganda state was organized for war, the Nyoro being its hereditary enemies. On becoming the first in the region to accept British influence, the Ganda gained even greater power and a special status in the politics of the Uganda Protectorate, a status they retained after the departure of the British. Between 1966 and 1993, however, the centuries-old kingship was abolished; the kabaka was restored in 1993, although his powers were reduced considerably. *See also* Buganda.

**Gander**, town, northeastern Newfoundland, Canada. It lies just north of Gander Lake, 206 miles (332 km) northwest of St. John's. Gander has one of the largest international airports in North America. The site was selected as an air base in 1935 by the British Air Ministry, and transatlantic flights began in 1939. During World War II it was a vital base for air ferries to Britain and Atlantic patrol aircraft. In 1945 the base became a civil airport controlled by the Newfoundland government, and in 1949, when Newfoundland became a province, the airport was acquired by the Canadian government. The modern town, built on a new site a few miles from the field, was incorporated in 1954. Gander's name derives from the river (and the abundant wild geese in the area) that feeds the lake. Pop. (1991) 10,339.

**Gandersheim** (Germany): *see* Bad Gandersheim.

**Gandhāra**, historical region in what is now northwestern Pakistan, corresponding to the Vale of Peshāwar and having extensions into the lower valleys of the Kābul and Swāt rivers.

In ancient times Gandhāra was a trade crossroads and cultural meeting place between India, Central Asia, and the Middle East. The region was subject to Achaemenian Persia in

the 6th and 5th centuries BC and was conquered by Alexander the Great in the 4th century BC. It was thereafter ruled by the Mauryan dynasty of India, under whom it became a centre for the spread of Buddhism to Afghanistan and Central Asia. Gandhāra was then successively ruled by Indo-Greeks, Śakas, Parthians, and Kushāns. After its conquest by Maḥmūd of Ghazna in the 11th century AD, the region was held by various Muslim dynasties.

Taxila and Peshāwar, ancient Gandhāra's chief cities, were important cultural centres. From the 1st century BC to the 6th–7th century AD, Gandhāra was the home of a distinctive art style that was a mixture of Indian Buddhist and Greco-Roman influences. *See* Gandhāra art.

**Gandhāra art**, style of Buddhist visual art that developed in what is now northwestern Pakistan and eastern Afghanistan between the 1st century BC and the 7th century AD. The style, of Greco-Roman origin, seems to have flourished largely during the Kushān dynasty and was contemporaneous with an important but dissimilar school of Kushān art at Mathura (Uttar Pradesh, India).

The Gandhāra region had long been a crossroads of cultural influences. During the reign of the Indian emperor Aśoka (3rd century BC), the region became the scene of intensive Buddhist missionary activity; and, in the 1st century AD, rulers of the Kushān empire, which included Gandhāra, maintained contacts with Rome. In its interpretation of Buddhist legends, the Gandhāra school incorporated many motifs and techniques from classical Roman art, including vine scrolls, cherubs bearing garlands, tritons, and centaurs. The basic iconography, however, remained Indian.

The Buddha preaching, relief from Gandhāra, schist, c. 2nd century AD; in the Prince of Wales Museum of Western India, Bombay  
P. Chandra

Gandhāra's role in the evolution of the Buddha image has been a point of considerable disagreement among scholars. It now seems clear that the schools of Gandhāra and Mathura each independently evolved its own characteristic depiction of the Buddha about the 1st century AD. The Gandhāra school drew upon the anthropomorphic traditions of Roman religion and represented the Buddha with a youthful Apollo-like face, dressed in garments resembling those seen on Roman imperial statues. The Gandhāra depiction of the seated Buddha was less successful. The schools of Gandhāra and Mathura influenced each other, and the general trend was away from a naturalistic conception and toward a more idealized, abstract image. The Gandhāran craftsmen made a lasting contribution to

Buddhist art in their composition of the events of the Buddha's life into set scenes.

**Gandhi, Indira**, in full **INDIRA PRIYADARSHINI GANDHI** (b. Nov. 19, 1917, Allahābād, India—d. Oct. 31, 1984, New Delhi), politician who served as prime minister of India for three consecutive terms (1966–77) and a fourth term (1980–84). She was assassinated by Sikh extremists.

Indira Gandhi  
AP/Wide World Photos

She was the only child of Jawaharlal Nehru, the first prime minister of independent India. She attended Visva-Bharati University, West Bengal, and the University of Oxford, and in 1942 she married Feroze Gandhi (d. 1960), a fellow member of the national Congress Party. She was a member of the working committee of the ruling Congress Party from 1955, and in 1959 she was elected to the largely honorary post of party president. Lal Bahadur Shastri, who succeeded Nehru as prime minister in 1964, named her minister of information and broadcasting in his government.

On Shastri's sudden death in January 1966, Gandhi became leader of the Congress Party (and thus also prime minister) in a compromise between the right and left wings of the party. Her leadership, however, came under continual challenge from the right wing of the party, led by a former minister of finance, Morarji Desai. In the election of 1967 she won a slim majority and had to accept Desai as deputy prime minister. In 1971, however, she won a sweeping electoral victory over a coalition of conservative parties. Gandhi strongly supported East Bengal (now Bangladesh) in its secessionist conflict with Pakistan in late 1971, and India's armed forces achieved a swift and decisive victory over Pakistan that led to the creation of Bangladesh.

In March 1972, after India's victory over Pakistan, Gandhi again led her New Congress Party to a landslide victory in national elections. Shortly afterward her defeated Socialist opponent charged that she had violated the election laws. In June 1975 the High Court of Allahābād ruled against her, which meant that she would be deprived of her seat in Parliament and would have to stay out of politics for six years. In response, she declared a state of emergency throughout India, imprisoned her political opponents, and assumed emergency powers, passing many laws limiting personal freedoms. During this period she implemented several unpopular policies, including large-scale sterilization as a form of birth control. When long-postponed national elections were held in 1977, Gandhi and her party were soundly defeated, whereupon she left office. The Janata Party took over the reins of government.

Early in 1978 Gandhi's supporters split from the Congress Party and formed the Congress (I)—"I" for "Indira"—Party. Gandhi was briefly imprisoned (October 1977 and December 1978) on charges of official corruption. Despite these setbacks, she won a new seat in Parliament in November 1978, and her Congress (I) Party began to gather strength. Dissension within the ruling Janata Party led

to the fall of its government in August 1979. When new elections for the Lok Sabha (lower house of Parliament) were held in January 1980, Gandhi and her Congress (I) Party were swept back into power in a landslide victory. Her son Sanjay Gandhi, who had become her chief political adviser, also won a seat in the Lok Sabha. All legal cases against Indira, as well as against her son, were withdrawn.

Sanjay Gandhi's death in an airplane crash in June 1980 eliminated Indira's chosen successor to the political leadership of India. After Sanjay's death, Indira groomed her other son, Rajiv, for the leadership of her party. During the early 1980s, Indira Gandhi was faced by threats to the political integrity of India. Several states sought a larger measure of independence from the central government, and Sikh extremists in the Punjab used violence to assert their demands for an autonomous state. In response, Gandhi ordered an army attack in June 1984 on the Golden Temple of Amritsar, the Sikhs' holiest shrine, which led to the deaths of more than 450 Sikhs. Five months later Gandhi was killed in her garden by a fusillade of bullets fired by two of her own Sikh bodyguards in revenge for the attack on the Golden Temple.

Gandhi adhered to the quasi-socialist policies of industrial development that had been begun by her father. She established closer relations with the Soviet Union, depending on that nation for support in India's longstanding conflict with Pakistan.

**BIBLIOGRAPHY.** Biographies include Mary C. Carras, *Indira Gandhi* (1979); Dom Moraes, *Indira Gandhi* (also published as *Mrs. Gandhi*, 1980); Nayantara Sahgal, *Indira Gandhi, Her Road to Power* (1982); Inder Malhotra, *Indira Gandhi: A Personal and Political Biography* (1989, reissued 1991); and Pupil Jayakar, *Indira Gandhi: An Intimate Biography* (1992).

**Gandhi, Mohandas Karamchand**, byname **MAHATMA** ("Great-Souled") **GANDHI** (b. Oct. 2, 1869, Porbandar, India—d. Jan. 30, 1948, Delhi), leader of the Indian nationalist movement against British rule, considered to be the father of his country. He is internationally esteemed for his doctrine of nonviolent protest to achieve political and social progress.

A brief treatment of Gandhi follows. For full treatment, see **MACROPAEDIA: Gandhi**.

Reared in a deeply religious home that decreed pacifism and the sanctity of all living things, Gandhi received an indifferent formal education in India and in 1888 began law studies in England. In quest of clerical work he went to South Africa (1893–1914) and was shocked at the racial discrimination there. He became an advocate for his fellow Indians in South Africa and undertook a series of challenges to the government that led to jail. After thorough soul-searching, he entered politics in India in 1919 to protest British sedition laws. He emerged as the head of the Indian National Congress and advocated a policy of nonviolent noncooperation to achieve Indian independence. In 1930 he led a march to the sea to protest the British-imposed tax on salt, and by the following spring the making of salt for personal use was permitted. Imprisoned throughout much of World War II, he negotiated with the British in August 1947 for an autonomous Indian state. In January 1948 he was shot by a Hindu fanatic.

Gandhi was one of the very few people who impressed an idea upon a historical epoch. That idea was nonviolence. Gandhi's creed of nonviolence insisted that people struggling for their rights should never violate their basic obligation to respect life.

**Gandhi, Rajiv**, in full **RAJIV RATNA GANDHI** (b. Aug. 20, 1944, Bombay, India—d. May 21, 1991, Sriperumbudur, near Madras), the leading general secretary of India's Congress (I) Party (from 1981) and prime minister of India (1984–89) after the assassination of his

mother, Indira Gandhi. He was himself assassinated in 1991.

Rajiv and his younger brother Sanjay (1946–80), the sons of Feroze and Indira Gandhi, were educated at the prestigious Doon School in Dehradun. Rajiv then attended Imperial College, London, and completed an engineering course at the University of Cambridge (1965). After returning to India, he acquired a commercial pilot's license and, beginning in 1968, worked for Indian Airlines.

While his brother was alive, Rajiv largely stayed out of politics; but, after Sanjay, a vigorous political figure, died in an airplane crash on June 23, 1980, Indira Gandhi, then prime minister, drafted Rajiv into a political career. In June 1981 he was elected in a by-election to the Lok Sabha (lower house of Parliament) and in the same month became a member of the national executive of the Youth Congress.

Whereas Sanjay had been described as politically "ruthless" and "willful" (he was considered a prime mover in his mother's state of emergency in 1975–77), Rajiv was regarded as a nonabrasive person who consulted other party members and refrained from hasty decisions. When his mother was killed on Oct. 31, 1984, Rajiv was sworn in as prime minister that same day and was elected leader of the Congress (I) Party a few days later. He led the Congress (I) Party to a landslide victory in elections to the Lok Sabha in December 1984, and his administration took vigorous measures to reform the government bureaucracy and liberalize the country's economy. Gandhi's attempts to discourage separatist movements in Punjab and Kashmir backfired, however, and after his government became embroiled in several financial scandals, his leadership became increasingly ineffectual. He resigned his post as prime minister in November 1989, though he remained leader of the Congress (I) Party. Gandhi was campaigning in Tamil Nadu for upcoming parliamentary elections when he was killed by a bomb carried by a woman who may have been associated with Tamil separatists.

**Gāndhinagar**, city, capital of Gujārāt state, west-central India. It lies on the banks of the Sābarmati River, north of the former capital of Ahmadābād. Built to supplant the former capital, the city was begun in 1966. The first state government offices were transferred there in 1970. An expressway connects Gāndhinagar with Ahmadābād. Pop. (1991 prelim.) 121,746.

**Gandía**, city, Valencia *provincia*, in the *comunidad autónoma* ("autonomous community") of Valencia, eastern Spain. It lies south of Valencia city at the mouth of the Serpis River. Once a Greek settlement, Gandía was occupied by the Moors in the 8th century and recaptured in 1252 by James I of Aragon, who ordered it rebuilt. It later became a duchy of the Borgia (Borja) family, whose 14th-century palace still stands. St. Francis Borgia, 4th Duke de Gandía, third general of the Society of Jesus, and a native of the city, founded the first Jesuit college there in 1546. There is also a 14th-century Gothic monastery.

A port city, Gandía has a shipping industry, as well as factories for tanning, silk spinning, and crate making. Pop. (1991 prelim.) 50,755.

**Gando** (Nigeria): see Gwandu.

**Gandzha** (Azerbaijan): see Gāncā.

**Gaṇeśa**, also spelled **GANESHA**, also called **GAṆAPATI**, elephant-headed Hindu god, the son of Śiva and Pārvatī. Gaṇeśa, considered the remover of obstacles, is the first god invoked at the beginning of worship or of a new enterprise, and his image is often seen at the entrance of temples or houses. He is a patron

of letters and learning, and he is the legendary scribe who wrote down the *Mahābhārata* ("Great Epic of the Bharata Dynasty") from Vyāsa's dictation. He is also called the chief of the *gaṅgas* (attendants of Śiva). Gaṅeśa is usually depicted coloured red; he is pot-bellied, has one tusk broken, and has four arms that

Gaṅeśa dancing, relief from Farrukhābād, Uttar Pradesh, India, 10th century AD; in the State Museum, Lucknow, India

Pramod Chandra

may hold a noose, a goad, a pot of rice or sweetmeats, and his broken tusk or that may bestow boons or protection. He rides on a rat.

One account of his birth is that Pārvatī formed him from the rubbings of her body so that he might stand guard at the door while she bathed. When Śiva approached, unaware this was his son, he was enraged at being kept away from his wife and sent his attendants against Gaṅeśa, whose head was cut off in the battle. To ease Pārvatī's grief, Śiva promised to cut off the head of the first living creature that he came across and join it to the body. This was an elephant. Gaṅeśa is a subsidiary figure in modern Hinduism. During the early part of the 20th century, however, his festivals were revitalized by the Indian independence leader Balgangadhar Tilak; Gaṅeśa-caturthī, the festival celebrating his birth, falls on the fourth day (*caturthī*) of the lunar month Bhādrapada (August–September) and is observed with particular enthusiasm in the state of Mahārāshtra.

**Ganesan, Sivaji**, original name VILLIPURAM CHINAIH PILLAI GANESAN (b. Oct. 1, 1927, Sirkali, Tamil Nadu, India), versatile star of Indian cinema.

Ganesan dropped out of school at a young age in order to join a boys' acting troupe. In 1946 he made his mark playing the title role of the Marāṭhā emperor Śivājī (the historical character who gave him his screen name) in C.N. Annadurai's play *Sivaji Kanda Indhu Rajyam*. When Annadurai formed the Dravida Munnertra Kazhagam (DMK) political party in 1949, Ganesan joined and made his film debut with the classic DMK film *Parasakthi* (1952). By the mid-1950s, Ganesan had begun to move away from the DMK and its atheistic policies. He soon attained fame by appearing in several mythological films—one such film, *Veerapandiya Kattaborman* (1960), is probably his best-known work. He was the most dominant actor in the Tamil film industry from the 1950s through the 1970s.

Ganesan is regarded by many as among the

most gifted actors in world cinema. Capable of a wide range of types, perhaps his most distinguishing feature is a highly expressive, resonant voice. In all, he appeared in more than 300 films, portraying the leading role in nearly all of them. He also dabbled in politics during the 1980s, serving in the Indian parliament and as president of the Tamil Nadu faction of Janata Dal.

**Gang** (people): *see* Acholi.

**Gang of Four**, Chinese (Pinyin) SIRENBANG, Wade-Giles SSU-JEN-PANG, the most powerful members of a radical political elite convicted for implementing the harsh policies directed by Communist Party chairman Mao Zedong during the Cultural Revolution (*q.v.*) of the 1960s and early '70s. The group included Mao's third wife, Jiang Qing, and Wang Hongwen, Zhang Chunqiao, and Yao Wen-yuan. Their backgrounds were similar in that, prior to 1966, all four were low-ranking officials who lacked leverage within the existing power structure. Shared traits included their ability to manipulate the mass media, their good standing with Mao, and their desire to overthrow moderate government officials who clustered around Liu Shaoqi and Deng Xiaoping.

The group came into prominence in 1965 when Wu Han's play *Hai Jui Dismissed from Office* was banned as a direct result of an investigation by Jiang into its political character, which resulted in a published denunciation of the play by Yao. This case set a precedent for radicalizing the arts and, in effect, signaled the beginning of the Cultural Revolution.

As the Cultural Revolution intensified, the members of the Gang of Four advanced to high positions in the government and the Communist Party. Manipulating the youthful Red Guards, the Gang of Four controlled four areas: intellectual education, science and technology, teacher-student relations and school discipline, and party policies regarding intellectuals. After the turmoil of the Cultural Revolution subsided in 1969, the Gang of Four maintained their power through control of the media and propaganda outlets and by their seeming adherence to Mao's policies and wishes. With Mao's death in 1976, however, the Gang of Four lost their remaining power and were imprisoned and later tried in 1980–81 for their activities during the Cultural Revolution. Jiang and Zhang both received suspended death sentences; Wang was sentenced to life imprisonment, and Yao to a 20-year term.

**Gaṅga** DYNASTY, either of two remotely related Indian dynasties. The Western Gaṅgas ruled in Mysore state (Gaṅgavāḍī) from about AD 250 to about 1004. The Eastern Gaṅgas ruled Kalinga from 1028 to 1434–35.

The first ruler of the Western Gaṅga, Koṅgaṇivarman, carved out a kingdom by conquest, but his successors, Mādhava I and Harivarman, expanded their influence by alliances with the Pallavas, Cālukyas, and Kadambas. By the end of the 8th century a dynastic dispute weakened the Gaṅgas, but Būṭuga II (c. 937–960) obtained territories between the Tungabhadra and the Krishna rivers. Repeated Cōḷa invasions cut the contact between Gaṅgavāḍī and the imperial capital, and Talakāḍ fell into the hands of the Cōḷa ruler Viṣṇuvardhana in about 1004. Most of the Western Gaṅgas were Jains, but some patronized Brahmanical Hinduism. They encouraged scholarly work in Kannada (Kanarese), built remarkable temples, and encouraged deforestation, irrigation, and cross-peninsular trade.

The Eastern Gaṅgas arose to intermarry with and challenge the Cōḷas and Cālukyas in the period when the Western Gaṅgas had been forced to abandon this role. Early dynasties of the eastern Gaṅgas ruled in Orissa from the

8th century; but Vajrahasta III, who assumed the title of Trikaṅgādhīpat (ruler of the three Kalingas in 1028, was probably the first to rule all three divisions of Kalinga. His son Rājārāja I waged war upon the Cōḷas and the Eastern Cālukyas and strengthened the dynasty by marrying a Cōḷa princess. Their son, Anantavarman Cōḷagaṅgadeva, ruled from the mouth of the Ganges River in the north to the mouth of the Godāvāri River in the south; he began building the great Jagannātha temple at Purī at the end of the 11th century. Rājārāja III ascended the throne in 1198 and did nothing to resist the Muslims of Bengal, who invaded Orissa in 1206. Rājārāja's son Anaṅgabhīma III, however, repulsed the Muslims and built the temple of Megheśvara at Bhuvaneśvara. Narasiṃha I, the son of Anaṅgabhīma, invaded southern Bengal in 1243, defeated its Muslim ruler, captured the capital (Gauḍa), and built the Sun Temple at Konārak to commemorate his victory. With the death of Narasiṃha in 1264, the Eastern Gaṅgas began to decline; the sultan of Delhi invaded Orissa in 1324, Muslims raided in 1353, and Vijayanagar defeated the Orissan powers in 1356. Narasiṃha IV, the last known king of the Eastern Gaṅga dynasty, ruled until 1425. The "mad king," Bhānudeva IV, who succeeded him, left no inscriptions; his minister Kapilendra usurped the throne and founded the Sūryavaṃśa dynasty in 1434–35. The Eastern Gaṅgas were great patrons of religion and the arts, and the temples of the Gaṅga period rank among the masterpieces of Hindu architecture.

**Ganges River**, Hindi GAṅGĀ, great river of the plains of northern India, held sacred by people of the Hindu faith.

A brief treatment of the Ganges River follows. For full treatment, *see* MACROPAEDIA: Asia.

The Ganges' five headstreams—the Bhāgirathi, Alaknanda, Mandākinī, Dhauliganga, and Pindar—all rise in northernmost Uttar Pradesh state in India. On its 1,560-mile (2,510-kilometre) course the Ganges flows in a southeasterly direction across the Gangetic Plain from Uttar Pradesh through the Indian states of Bihār and West Bengal.

Its major tributaries include the Yamuna, Rāmganga, and Ghāghara rivers in Uttar Pradesh and the Gandak, Burhi Gandak, and Kosi rivers in Bihār. In central Bangladesh the Ganges is joined from the north by the great Brahmaputra River near Goalundo Ghāt and from the northeast by the Meghna River above Chāndpur. Their combined waters empty into the Bay of Bengal through innumerable channels that form a delta 200 miles (320 km) wide, which is shared by India and Bangladesh.

**Ganges-Yamuna Doab**, segment of the Gangetic Plain in western and southwestern Uttar Pradesh state, northeastern India, with an area of about 23,360 square miles (60,500 square km). It lies between the Ganges and Yamuna rivers, west of the Upper Ganges Plain. The doab is about 500 miles (800 km) in length and 60 miles (100 km) in width and consists of a wide trough between the Great Himalayas in the north and the Deccan Plateau in the south. It was formed by sediment deposited by rivers flowing southward from the Himalayas.

The doab can be divided into three sections: Upper, Middle, and Lower. The Upper Doab extends from Hardwār town on the north to Aligarh town on the south. It has a gentle slope and is crisscrossed by a number of streams. Secondary transverse slopes on older floodplains have developed in the Middle Doab. The topography flattens out in the Lower Doab, where the Sind, Betwa, and Ken streams run parallel to each other. Geologically, the whole region forms part of the alluvial Indo-

Ganges trough. Forests, occurring in patches, are composed of acacia and teak. The regional economy is dominated by agriculture based on intensive cultivation and crop rotation; crops include cereals, pulse (legumes), sugarcane, fruits, and vegetables. Livestock raising and dairy farming are also important. The region is highly industrialized and produces refined sugar, printed calico, fans, automobile radiators, insulated wire, textile machinery, textiles, brass and copper utensils, and railroad equipment. Roads and railways link the regional centres, and there are airports at Kānpur and Allahābād. Meerut, Aligarh, Sahāranpur, and Ghāziābād are other important towns. The doab is one of the most fertile and densely populated regions in India.

**ganglion**, plural **GANGLIA**, dense aggregate of nerve-cell bodies present in most animals more advanced than cnidarians. In flatworms (e.g., *Planaria*) there are two lateral neuronal cords that carry impulses to and from a pair of ganglia at the head of the animal. In more advanced groups, such as earthworms and arthropods, there are pairs of ganglia at intervals along the body that largely control the actions of each body segment, as well as a larger, dorsal pair in the head. This latter pair of ganglia, considered the brain in these more advanced invertebrates, acts mostly to inhibit responses rather than to direct them. In vertebrates the term ganglion denotes a cluster of neural bodies outside the central nervous system; a spinal ganglion is such a cluster of nerve bodies positioned along the spinal cord at the root of a spinal nerve. The dorsal root ganglia contain the cell bodies of afferent nerve fibres (those carrying impulses toward the central nervous system); efferent motor neurons are present in the ventral root ganglia.

**ganglion blocking agent**, any drug that blocks the conduction of an impulse from one nerve cell to another through a ganglion (e.g., group of nerve cell bodies) of the autonomic nervous system.

This blockage causes vascular walls to dilate, resulting in a decrease in blood pressure. Ganglionic blocking agents also decrease blood flow through the kidneys and the volume of gastric and salivary secretions. Partial to total impairment of the voiding contractions of the urinary bladder is one undesirable effect.

These drugs were formerly used in routine treatment of hypertension but have been replaced by more specific agents; they are still used in the emergency treatment of acute hypertensive cardiovascular disease. A secondary use is to reduce hemorrhage during surgery. See also neuromuscular blocking agent.

**Gangra** (Turkic): see Çankırı.

**gangrene**, localized death of animal soft tissue, caused by prolonged interruption of the blood supply that may result from injury or infection. Diseases in which gangrene is prone to occur include arteriosclerosis, diabetes, Raynaud's disease, thromboangiitis obliterans (Buerger's disease), and typhus. It also may occur after severe burns, freezing, or prolonged bed rest (bed sores).

Gangrene is differentiated as being either dry or moist. Dry gangrene results from a gradual decrease in the blood supply (as from diabetes or arteriosclerosis) in the affected area, often an extremity. The diseased part may at first be discoloured and cold to the touch; later it becomes distinct from nearby healthy tissue, turning dark and dry. If the infection is confined to a small area, the diseased tissue may eventually dry up completely and fall off. Treatment involves improving the blood flow to the affected area.

Moist gangrene develops when the blood supply is suddenly cut off, as by a severe burn or an arterial blood clot. Tissue that has not been destroyed by the trauma begins to leak

fluids, which then foster the growth of bacteria. The affected area becomes swollen and discoloured and later becomes foul-smelling. If not treated, the infection can spread beyond the wound and cause death. The administration of antibiotics is the principal treatment, which may be supplemented by the removal of diseased tissue to stop the spread of the infection.

A different and more virulent form, gas gangrene, is caused by infection with bacteria of the genus *Clostridium*, which grow only in the absence of oxygen. It typically develops in deep crushing or penetrating wounds, as in war wounds, that are improperly cleaned; it may also be a sequel to an improperly performed induced abortion. Within three or four days the wound begins to exude brownish, foul-smelling pus. Numerous gas bubbles, produced by a toxin released by the bacteria, form under the skin. The toxin is extremely lethal, and if the affected area is not treated, the infection spreads rapidly, causing death. Treatment involves removing all dead and diseased tissue and administering antibiotics. In some instances a polyvalent antitoxin derived from horses is also given, and occasionally a severely affected limb is placed in a high-pressure oxygen chamber to inhibit the growth of bacteria. See also infarction; necrosis.

**Gangtok**, town, capital of Sikkim state, north-eastern India. It lies at an elevation of 5,600 feet (1,700 m). The town (the name of which means "top of the hill") rises over slopes extensively terraced in corn (maize). It was the

The Buddhist monastery of Rumtek, near Gangtok, Sikkim, India

N. Merrifield—Shostal Assoc./EB Inc

governmental seat of the kingdom of Sikkim until the monarchy was abolished (1975) and Sikkim was annexed by India (1976).

The capital serves as a market centre for corn, rice, pulses, and oranges. It was an important point on the India-Tibet trade route via Nathula (Nathu Pass), 13 miles (21 km) northeast, until the border with Tibet was closed in 1962. From Gangtok the North Sikkim Highway (1962) reaches the Tibetan border areas via Lachung and Lachen, and the National Highway runs southwest to India.

Gangtok has a hospital, secondary school, and law court and some modern shops, hotels, and cinemas. The town's landscape is marked by the former royal palace and chapel, two monasteries, the open-air Lall Market, the Namgyal Institute of Tibetology (1958; a centre for research in Mahāyāna Buddhism with a library and a museum), and the Cottage Industries Institute (1957). The noted Buddhist monastery of Rumtek is 5 miles (8 km) southwest, and the royal cremation ground is at nearby Lukshiyama. In Gangtok are government-maintained nurseries for cardamom—an important export—and subtropical fruits, and there is an experimental agricultural station at Tadong, to the south. The population includes Nepalese, Tibetans, Lepchās, and Indians. Pop. (1991) 25,024.

**Ganioda'yo**, English **HANDSOME LAKE** (b. c. 1735, Ganawaugus, N.Y.—d. Aug. 10, 1815, Onondaga, N.Y., U.S.), Seneca Indian chief who developed a new religion for the Iroquois (see Handsome Lake cult). The cult was so

successful that in the 20th century several thousand Indians still adhered to it.

After a somewhat dissolute life, Ganioda'yo became seriously ill in 1799 and was near death. On his recovery he declared that he had been visited by three spirits, who revealed to him the will of the Great Spirit. From 1800, as an itinerant preacher of the religion that he called Gai'wiio ("Good Message"), he urged his people to refrain from adultery, drunkenness, laziness, and witchcraft. He explained his beliefs to Thomas Jefferson on the occasion of a visit to that president. His combination of old beliefs with Christian ethics provided the Iroquois with a faith that revitalized their civilization at a time when it was threatened with extinction by the white man's culture.

**Ganivet y García, Ángel** (b. Dec. 13, 1865, Granada, Spain—d. Nov. 29, 1898, Riga, Latvia, Russian Empire), Spanish essayist and novelist, considered a precursor of the Generation of '98 because of his concern for the spiritual regeneration of his country. Fluent in five languages, he served with the Spanish consular service in Antwerp, Helsinki, and Riga. An anguished and skeptical man facing an uncertain prognosis of a progressive disease, and disillusioned in love, he drowned himself in the Dvina River at age 33.

Ganivet's most important work is the *Idearium español* (1897; *Spain, an Interpretation*), an essay that examines the Spanish temperament and the historical basis of the political situation of his country. In this essay he asserts that Spaniards are basically stoical and that the country has wasted its energies on territorial aggrandizement. He maintains that Spain has suffered from "abulia," a state of paralysis of the will.

In addition to this work, Ganivet published two novels of a satirical-social nature: *La conquista del reino de Maya* (1897; "The Conquest of the Mayan Kingdom") and *Los trabajos del infatigable creador Pío Cid* (1898; "The Labors of the Indefatigable Creator Pío Cid"). In the former, the author satirizes European civilization and the customs of modern Spanish society. The latter novel addresses the problem of national apathy and calls for a revitalization of Spain. In the brilliant *Cartas finlandesas* (1905; "Letters from Finland"), Ganivet presents a contrast between Spanish and Nordic life and character.

**Ganku**, original name **SAEKI KISHI** (b. 1756, Kanazawa, Japan—d. Jan. 19, 1839, Kyōto), Japanese painter of the late Tokugawa period who established the Kishi school of painting.

A retainer of Prince Arisugawa in Kyōto and a holder of high rank, Ganku studied various styles of painting, including those of the Maruyama school, known for its realism, and of the Chinese painter Shen Nan-p'in, who had visited Japan in 1731. Ganku developed a realistic solid style and painted portraits, landscapes, flowers, and birds. He was particularly noted for his pictures of tigers.

**gannet**, any of three oceanic bird species within the family Sulidae (order Pelecaniformes). Closely related to the boobies and variously classified with them in the genus *Sula* or separated as *Morus* (or *Moris*), the gannets are the best known of the Sulidae. They are found in the northern Atlantic, where they are the largest seabirds, and also in temperate waters around Africa, Australia, and New Zealand. Adult gannets are mainly white with black-tipped wing feathers. They have a large, yellowish or buff-coloured head marked with black around the eyes. They have a tapered beak and a pointed tail. Gannets dive with half-closed wings into the sea in order to catch fish and squid. They waddle on land but are expert fliers, alternating rapid

wing beats with gliding. They spend most of their lives over water. Gannets nest in dense colonies on cliffs, brooding a single bluish, chalky egg for six or seven weeks in a nest of seaweed or mud. The young birds are fed by regurgitation and reach maturity in the third or fourth year.

Northern gannets (*Morus bassanus*)

William and Laura Riley

The largest of the three species is the 100-centimetre (40-inch) northern gannet, *Morus bassanus* (or *Sula bassana*), sometimes called solan goose; it breeds on islands in Canada, Greenland, Iceland, and northeastern Europe, wintering to the Gulf of Mexico, Morocco, and the Mediterranean. The two slightly smaller southern species are the Cape gannet (*M. capensis*), which breeds on islands off South Africa, and the Australian gannet (*M. serrator*), which breeds around Tasmania and New Zealand.

**Gannett, Frank Ernest** (b. Sept. 15, 1876, Bristol, N.Y., U.S.—d. Dec. 3, 1957, Rochester, N.Y.), American publisher who established a major chain of daily newspapers in small and medium-sized U.S. cities. During his career Gannett bought many newspapers and often merged them, creating one paper from two or more.

Gannett was reared in rural upstate New York, where his father was a farmer who later came to own several hotels. Frank attended Cornell University, where he worked on the school newspaper and was the campus correspondent for the *Ithaca Journal* (which he later owned) and the *Syracuse Herald*. Gannett graduated from Cornell in 1898, and in 1900 the *Ithaca Journal* hired him as city editor. He soon became managing editor and business manager, then moved through a variety of other editorial jobs with various newspapers until 1906. In that year he bought a half-interest in the *Elmira* (N.Y.) *Gazette*, his first publishing venture. In 1907 Gannett merged the *Gazette* with the *Elmira Star*, creating the *Star-Gazette*, eliminating competition, and setting a pattern for future acquisitions. In the next two decades Gannett acquired various newspapers in medium-sized cities in New York state; his strategy was to pursue the profitable advertising and expandable circulations presented by one-newspaper towns and cities, rather than trying to obtain possession of a single large, prestigious big-city newspaper.

Becoming interested in radio, Gannett in 1922 backed Lawrence G. Hickson's purchase of station WHQ in Rochester, N.Y., the first link in a Gannett broadcasting chain. By 1954 he owned 22 newspapers as well as four radio and three television stations. In general, Gannett gave the editors of his papers control over editorial policy, but he would not permit them

to accept liquor advertisements. By the late 1970s the Gannett Company, Inc., was the United States' largest newspaper chain in terms of the number of different newspapers published.

**Gannett Co., Inc.**, one of the largest newspaper publishers in the United States. It also has interests in broadcasting and outdoor advertising. It is headquartered in Arlington, Va.

The company was started by the newspaperman Frank Ernest Gannett (*q.v.*), who in 1906 began buying small newspapers in New York state. The company was incorporated in 1923, and it grew as Gannett continued to purchase the newspapers of small and medium-sized cities. These newspapers were usually the only ones published in their city and so could be run very profitably. The company's growth was further spurred by the attention it paid to advertising and circulation and by its tight control of costs. By the late 1980s the Gannett Co. owned more than 90 daily newspapers with a total circulation of more than 6,000,000. In 1982 the company began publishing *USA Today*, the United States' first national, general-interest newspaper. In subsequent years the company began buying larger newspapers, including the *Des Moines Register* (1985), the *Detroit Evening News* (1986), and both of the newspapers in Louisville, Ky. This pattern of buying all the newspapers in an area, slashing subscription rates to levels which (according to critics) only a national conglomerate could sustain, and then raising advertising rates once control over the local market had been secured, brought Gannett severe criticism as well as lawsuits. Smaller community and privately owned newspapers charged the media giant with predatory practices and violations of antitrust laws.

Meanwhile, Gannett continued to expand. In 1995 it acquired Multimedia Inc., a media firm that syndicated several talk shows and owned newspapers and television stations throughout the South. Four years later the company purchased Newsquest PLC, a regional newspaper publisher that was one of the largest in England. By the end of the 20th century, Gannett ran 85 daily newspapers, which had an average daily circulation of some 7,000,000. The company also owned numerous radio and television stations and the largest billboard-advertising firm in the country and, through a foundation, financially supported the prestigious Gerald Loeb Awards, which recognize distinguished business and financial journalism.

**Gans, Eduard** (b. March 22, 1798, Berlin—d. May 5, 1839, Berlin), a major German jurist and, for a time, a potent force in the revival of studies of Jewish culture.

The son of prosperous Jewish parents, Gans studied law in Berlin, Göttingen, and Heidelberg (Ph.D., 1820), where he became a disciple of the philosopher Hegel. In 1819, in collaboration with Leopold Zunz, later a Judaic scholar, and Moses Moser, a merchant and mathematician, Gans founded and became president of the Society for Jewish Culture and Science, which attempted to demonstrate Jewish worth and bring about a rapprochement between Christians and Jews. The society was dissolved in 1824, but not without having initiated some important studies of Jewish culture, such as Zunz's biography of the great Jewish commentator Rashi (1040–1105) and Gans's analysis of the Mosaic law of inheritance.

In 1820 Gans became a lecturer on law in Berlin, but his religious faith ruled out his holding high-level positions. He converted to Christianity in 1825 and the following year was appointed professor of law at the University of Berlin. Gans's major work is *Das Erbrecht in weltgeschichtlicher Entwicklung*, 4 vol. (1824–35; "Historical Development of Inheritance Law"); his decision to write a his-

torical work may have been influenced by the number of historical works in Hegel's corpus. Gans's treatise is valuable not only for its extensive survey of facts but also for its presentation of a general theory on the slow evolution of legal principles.

The Prussian government disapproved of Gans's liberal political views and banned his *Vorlesungen über die Geschichte der letzten fünfzig Jahre* (1833–34; "Lectures on the History of the Last Fifty Years"). His other works include studies of Roman civil law and an analysis of the basis of property. Gans edited the *Philosophie der Geschichte* ("Philosophy of History") in Hegel's *Werke*, to which he also wrote a preface.

**Gans, Joe**, byname of JOSEPH GAINES (b. Nov. 25, 1874, Baltimore, Md., U.S.—d. Aug. 10, 1910, Baltimore), American professional boxer known as the Old Master, perhaps the greatest fighter in the history of the lightweight division. Because he was black, he was compelled by boxing promoters to permit less-talented white fighters to last the scheduled number of rounds with him and occasionally to defeat him. He was also forced to fight at unnaturally low weights, and, perhaps as a result, he was so weakened that he contracted tuberculosis and died while a young man.

After 11 years of fighting, Gans won the world lightweight title by knocking out Frank Erne in one round at Fort Erie, Ont., on May 12, 1902. On Sept. 30, 1904, he fought a 20-round draw with the great welterweight champion Joe Walcott, who thereby retained his crown. Gans was already ill when he defended his lightweight championship against Battling Nelson at Goldfield, Nev., on Sept. 3, 1906. Gans, who gave one of his finest performances, won this match when Nelson deliberately fouled him in the 42nd round. In a return bout with Nelson in San Francisco on July 4, 1908, Gans was knocked out in 17 rounds.

Gans spent several months in Arizona in an unsuccessful attempt to arrest his disease. When he returned to Baltimore to die, his train was greeted at each station by groups of boxing fans, and his impending death was treated as a national calamity by the press.

**Gansu** (China): see Kansu.

**Ganymede**, Greek GANYMĒDĒS, Latin GANYMĒDES, or CATAMITUS, in Greek legend, the son of Tros (or Laomedon), king of Troy.

Ganymede and Zeus in the form of an eagle, antique marble statue; in the Vatican Museum

Anderson—Alinari from Art Resource/EB Inc.

Because of his unusual beauty, he was carried off either by the gods or by Zeus, disguised as an eagle, or, according to a Cretan account, by Minos, to serve as cupbearer. In compensation, Zeus gave Ganymede's father a stud

of immortal horses (or a golden vine). From early times it was believed that Ganymede's kidnapper had a homosexual passion for him, hence the term *catamite*, derived from the popular Latin form of his name. He was later identified with the constellation Aquarius.

**Ganymede**, also called JUPITER III, largest of Jupiter's moons and of all the moons in the solar system. One of the four Galilean satellites, it was discovered by the Italian astronomer Galileo in 1610. It was probably also discovered independently that same year by the German astronomer Simon Marius.

Ganymede has a diameter of about 5,270 km (3,275 miles), which makes it larger than the planet Mercury. It orbits Jupiter at a distance of 1,070,000 km (665,000 miles). Its relatively low density of 1.93 grams per cubic centimetre indicates that its composition is roughly half rock and half water ice by mass. Spacecraft investigations of its gravity field reveal that the interior consists of a dense, iron-rich core with a radius of 1,500 km (930 miles) surrounded by a rocky lower mantle, which is wrapped with a layer of ice some 700 km (430 miles) thick. The iron core produces a magnetic field one percent as strong as Earth's.

Ganymede was observed at close range in 1979 by the Voyager spacecraft and by the Galileo orbiter beginning in the mid-1990s. The surface comprises two principal types of terrain, one dark and one bright. The dark terrain is present in broad, roughly polygonal regions separated by bands of bright terrain. Both terrains have impact craters. The density of craters is higher in the dark terrain, indicating that it is the older of the two types. The polar regions are lightly frosted with fresh ice and crowned by flickering auroras.

The bright terrain is covered with complex patterns of long narrow grooves. This terrain probably formed during a period of tectonic activity in which internally generated stresses disrupted and fractured the crust. Exactly when this activity occurred is not known, but the crater density in the bright terrain suggests that it was early in Ganymede's history. That history must have included some intense internal heating—perhaps tidal heating generated by Jupiter's gravity—in order to produce the internal differentiation observed today.

**Ganz, Rudolph** (b. Feb. 24, 1877, Zürich—d. Aug. 2, 1972, Chicago), pianist, conductor, and composer, who introduced works by contemporary composers such as Bartók, Ravel, and Vincent d'Indy, and who revived little-played older works in the keyboard repertory.

Ganz made his official debut in 1899 with the Berlin Philharmonic. He directed the piano department of Chicago Musical College (now part of Roosevelt University) from 1900 to 1905 and became vice president in 1927, president in 1933, and president emeritus in 1954. He conducted the St. Louis Symphony (1921–27) and the New York Philharmonic Young People's concerts (1938–49). His compositions include a symphony, works for piano and voice, and more than 200 songs.

**Ganzhou** (China): *see* Kan-chou.

**Gao**, historically KAWKAW, town, eastern Mali, West Africa, situated on the Niger River. Founded by fishermen in the 7th century AD, it is one of the oldest trading centres in West Africa. Gao became the capital of the Songhai Empire in the early 11th century. Under Songhai rule, the town thrived as a major trans-Saharan trading centre for gold, copper, slaves, and salt. The rulers of the Kingdom of Mali annexed Gao in 1325, but the Songhai people regained control of it some 40 years later. The Moroccans ended Songhai rule over Gao permanently in 1591, and the town's importance as a commercial centre declined thereafter. Today Gao serves as a terminus for large steamers emanating from Mopti and Koulikoro. A road crossing the Sahara links

the town with Algeria, and other roads connect Gao with the Malian towns of Timbuktu and Mopti. Pop. (1996) 62,667.

**Gao** (Chinese surname): *see under* Kao, except as below.

**Gao Gang**, Wade-Giles romanization KAO KANG (b. c. 1902, Heng-shan, Shensi Province, China—d. c. 1955, China), one of the early leaders of the Chinese Communist Party and one of the most important figures in the Communist government established after 1949. His purge in 1954–55 was the biggest scandal in the Chinese Communist movement from the mid-1930s to the 1960s.

Gao joined the Chinese Communist Party in 1926 and spent much of the next 10 years participating in Communist guerrilla operations in his home Shensi Province. In the early 1930s he helped establish a Communist guerrilla base on the Shensi-Kansu provincial border. When the main Red Army under Mao Zedong occupied the area after completing the Long March, Gao became an important Communist official. By the early 1950s he was a full Politburo member, one of Mao Zedong's closest comrades, and the party and government head of the country's single most industrialized area, Manchuria (administratively designated the Northeast Region). Gao exercised virtually autonomous power in Manchuria and as such was the country's most powerful regional leader. He committed suicide shortly before he was publicly condemned by the party for deviating from Communist policies in April 1955. Gao's fall was accompanied by the purge of virtually all the key party leaders in the Northeast Region. The most credible speculation is that Gao and his close associates were purged because they had vehemently asserted their administrative independence of the central government in Peking.

**Gao Xingjian**, Wade-Giles romanization KAO HSING-CHIEN (b. Jan. 4, 1940, Kan-chou, Kiangsi province, China), Chinese émigré novelist, playwright, and critic who was awarded the 2000 Nobel Prize for Literature for "an oeuvre of universal validity, bitter insights and linguistic ingenuity." He was also renowned as a stage director and as an artist.

Gao was educated in state schools and from 1957 to 1962 attended the Peking (Beijing) Foreign Languages Institute, where he earned a degree in French. Persecuted as an intellectual during the Cultural Revolution, Gao was forced to destroy his early writings and was later sent to a reeducation camp, where he endured nearly six years of hard labour. Afterward, he was assigned by the government to work at the Foreign Languages Press. He became a translator, but was unable to publish his work or travel abroad until 1979.

Gao first gained critical recognition with the publication of the novella *Han-yeh chung te hsing-ch'en* (1980; "Stars on a Cold Night"). In 1981 he became a resident playwright with the Peking People's Art Theatre, and in 1982 his first play, *Chieh-tui hsin-hao* (*Alarm Signal*), written in collaboration with Liu Huiyuan, was performed. His second and most celebrated play, *Ch'e-chan* (1983; *Bus Stop*), incorporated various techniques of avant-garde European theatre. It was openly condemned by Communist Party officials. Gao continued to explore the boundaries of experimental drama with plays such as *Yeh-jen* (1985; *Wild Man*) and, most notably, *Pi'an* (1986; *The Other Shore*), which was quickly banned by the authorities. Gao then embarked on a 10-month walking tour following the course of the Yangtze River—a spiritual pilgrimage that became the basis for his first novel, *Ling-shan* (1989; *Soul Mountain*). In 1987 he settled in France as a political refugee and subsequently became a French citizen. Following the publication of his play *T'ao-wang* (1989; *Fugitives*), set against the backdrop of the brutal 1989 sup-

pression of student demonstrations in Tiananmen Square, Gao was declared *persona non grata* by the Chinese regime and his works were banned. Gao wrote in both Chinese and French. Several of his plays have been published in *The Other Shore: Plays by Gao Xingjian* (1999).

**gaon** (Hebrew: "excellency"), plural GEONIM, the title accorded to the Jewish spiritual leaders and scholars who headed Talmudic academies that flourished, with lengthy interruptions, from the 7th to the 13th century in Babylonia and Palestine. The chief concern of the *geonim* was to interpret and develop Talmudic Law and to safeguard Jewish legal traditions by adjudicating points of legal controversy. Their replies (*responsa*) were quoted far beyond the limits of their own communities and are of great value in studying the Jewish history and theology of the period. The *geonim* continued a tradition of scholarship begun long before by the *soferim* (teachers and interpreters of biblical law) and kept alive in subsequent centuries by the *tannaim* and *amoraim* (who, respectively, produced the compilation of law called the Mishna and wrote commentaries on the Mishna, called Gemara).

The prestige of the *geonim* gradually declined with the establishment of Talmudic academies elsewhere and the acceptance of local scholars as competent authorities on Jewish Law.

After the gaonic period, the term *gaon* was used simply as a title of honour to describe excellence in Jewish learning.

**Gaoyao** (China): *see* Chao-ch'ing.

**Gap**, town, capital of the Hautes-Alpes *département*, Provence-Alpes-Côte-d'Azur region, southeastern France, south-southeast of Grenoble. Situated at an altitude of 2,406 ft (733 m) in a valley on the right bank of the Luye, a tributary of the Durance, it is a tourist centre surrounded by mountains. Through the town pass the main road from Briançon to the Rhône Valley and the Route Napoléon—the road that Napoleon took in 1815 when he crossed the Alps into France on his return from exile on Elba. Gap was the first place where he was well received. Known as Vapincum to the Romans, the town was founded by the Roman emperor Augustus in about 14 BC. The town remained under episcopal rule until 1512, when it was annexed by France. Gap has an agricultural market and is an industrial centre. Pop. (1999) 36,262.

**gaper clam**, also called HORSE CLAM (*Tresus nutalli* and *Tresus capax*), either of two species of bivalve mollusks of the family Macluridae. These clams live in sand and mud flats along the coast of western North America from British Columbia to Baja California. The shells of both species reach about 200 millimetres (8 inches) in length. They are roughly oblong in shape and creamy white in colour. Gaper clams have long, fused siphons that are contained in sheathlike tubes; the siphons are not fully retractable into the shell. The clams burrow up to one metre (three feet) deep into sediment. Gaper clams are edible and are heavily fished at spring tides. They are commonly infected with larval tapeworm cysts, but these are harmless to humans.

**gar**, any of several large North or Middle American fishes of the genus *Lepisosteus*, in the family Lepisosteidae. Gars, which are related to the bowfin in the superorder Holostei, are confined chiefly to fresh water, though some of the eight or so species descend to brackish or even salt water. They frequently bask like logs at the surface in sluggish waters and commonly breathe atmospheric air. Their jaws and face form a sharp-toothed beak, and their bodies are encased in an armour of diamond-shaped, thick, enamelled (ganoid) scales.

During the Eocene Epoch (57.8 to 36.6 million years ago), gars lived in Europe as well as in North America. One reason for their survival is thought to be that their relatively large, yolk-filled, greenish eggs are highly toxic

Short-nosed gar

Treat Davidson from The National Audubon Society Collection/Photo Researchers

to prospective predators. The eggs are laid in shallows in the spring; the hatchlings grow remarkably fast, feeding from the start on the hatchlings of other fish and even minnows, and soon become such voracious predators that measures are often applied to reduce their numbers. The long rows of needlelike teeth are very effective in capturing prey. The beak is very long and forcepslike in the longnose gar, or billfish (*Lepisosteus osseus*), but broad and relatively short in the alligator gar (*L. spatula*) of the southern United States. The alligator gar, reaching a length of about 3 m (10 feet), is one of the largest of all freshwater fishes. Gars are edible but are almost never eaten in the central and northern United States. They are sometimes baked in their own armour. Some artisans fabricate the enameled scales into novelty jewelry.

Especially in Europe, the name gar, or garfish, or gar pike, is applied to the needlefish (*q.v.*) of the family Belontiidae. In Australia the term is used for the halfbeak (*q.v.*), a relative of the needlefish.

**GAR (U.S.):** *see* Grand Army of the Republic.

**garabā**, also spelled *GARBĀ*, dance form popular at festival times in Gujārāt, India. It is a simple, joyful dance, based on a circular pattern and characterized by a sweeping action from side to side accompanied by hand clapping.

At the Daśaharā festival (September) after the monsoon rains, girls carrying pitchers go from house to house and dance around the *garabi*, decorated pots containing offerings that are hung in the doorways. Later they celebrate by dancing around images of the goddess of plenty and prosperity, Mātājī. The *garabā* dances are also performed at the Holi spring festival, when many activities centre on the Krishna legends. Folk dances similar to the *garabā* are performed in other parts of India, especially Tamil Nadu and Rājasthān.

**Garamba National Park**, French *PARC NATIONAL DES GARAMBA*, national park in north-eastern Zaire, bordering on The Sudan. The park, which was created in 1938, has an area of 1,900 square miles (4,920 square km) and is a continuation of the Sudanese savanna fed by the Garamba and Dungu rivers. Wildlife includes the rare white rhinoceros, hippopotamuses, and giraffes. In the south there is an elephant station, Gangala-Na-Bodio, one of the few of its kind in the world, where the animals are domesticated for use in forestry.

**Garamond, Claude**, Garamond also spelled *GARAMONT* (b. 1499, Paris, France—d. 1561, Paris), French type designer and publisher.

Garamond was apprenticed about 1510 to Antoine Augerau and by 1520 was working

with the typefounder Geoffroy Tory. His first romans and his *grecs du roi* were cut for the firm of Robert Estienne. In 1545 he began to publish books; apparently he was not successful in business, for he died in poverty.

Garamond was one of the first punch cutters to work independently of printers. His roman fonts, cut from 1531 onward, surpassed the best existing romans in grace and clarity and influenced European punch cutters for 150 years. His Greek type set the pattern for Greek printing until the early 19th century. Modern typefaces bearing his name were patterned after other faces mistakenly attributed to Garamond.

**Garand, John C.**, in full *JOHN CANTIUS GARAND* (b. Jan. 1, 1888, St. Rémi, Quebec, Can.—d. Feb. 16, 1974, Springfield, Mass., U.S.), Canadian-born U.S. firearms engineer, inventor of the M1 semiautomatic rifle, with which U.S. infantrymen fought in World War II and the Korean War.

In 1898 Garand's family moved to Connecticut, where he learned the machinist's trade in textile mills. As a young man he worked in precision-tool factories in Providence, R.I., and New York City. During World War I he designed a lightweight, fully automatic machine rifle; it was rejected by the U.S. Army but earned Garand a position in 1918–19 as a gun designer with the National Bureau of Standards. He was then transferred to the Springfield (Mass.) Armory, where he was put to work designing a semiautomatic replacement for the Springfield bolt-action repeater. In 1920 he became a U.S. citizen.

After 17 years of working under exacting and often contradictory military specifications, Garand came up with a gas-operated weapon of .30-inch calibre that was 43 inches (109 cm) long yet weighed only 9.5 pounds (4.3 kg). His rifle was fed from an eight-round clip. Adopted in 1936, the M1 became the first standard-issue autoloading infantry rifle in the world. Millions of the accurate, efficient, and durable weapons were produced in World War II, giving U.S. troops such an advantage in firepower that General George S. Patton called the M1 "the greatest battle implement ever devised." Signing over all patents of his invention to the U.S. government, Garand worked on other experimental rifles until he retired in 1953.

**Garanhuns**, city, eastern Pernambuco *estado* ("state"), northeastern Brazil. The city lies in the Serra Garanhuns, at 2,841 feet (866 m) above sea level. It was elevated to city status in 1874. Garanhuns is a trade and manufacturing centre serving its coffee- and cotton-producing municipality. It is also a popular resort, known for its cool climate and mineral waters. Roads link Garanhuns to Recife, the state capital, to the northeast and to other urban centres in Pernambuco and Alagoas states. Pop. (1991 prelim.) 86,593.

**Garašanin, Ilija**, original name *ILIJA SAVIĆ* (b. Jan. 16 [Jan. 28, New Style], 1812, Garaši, Serbia—d. June 16 [June 28], 1874, Belgrade), statesman and administrator of Serbia who was twice prime minister (1852, 1861–67).

The son of a prominent merchant, Garašanin became a customs official in 1834 and joined the army in 1837, where he served as colonel and commander. Changing sides in the rivalry between the two dynastic families—the Obrenović and the Karađorđević—he went into exile when Prince Miloš Obrenović abdicated (1839), but then he helped to depose Prince Michael Obrenović to pave the way for the accession of Prince Alexander Karađorđević (1842). Garašanin was rewarded with the posts of home secretary (1843) and prime minister and foreign secretary (1852). In 1844 he wrote a memorandum called the "Draft Plan," in which he called for a general rising of Christians under Turkish rule and

the unification of all Serbs in their restored medieval empire. During the Hungarian revolution of 1848, he hoped to liberate the South Slavs of the Austrian Empire, but Alexander decided to remain neutral. Considered unfriendly by the Russians because of his pro-Western views, Garašanin was dismissed in 1853 by Alexander under Russian pressure. He was mainly responsible for the abdication of Prince Alexander (1858) but took no part in politics during the second reign of Miloš Obrenović (1858–60).

When Prince Michael Obrenović succeeded Miloš, Garašanin became prime minister and foreign secretary (1861–67). As during his first term as prime minister, he worked to modernize Serbia through enlightened legislation administered by an efficient bureaucracy. In foreign policy he sought to implement his "Draft Plan." Though he was not in office during the Congress of Paris (1856), he is credited with the collective guarantee of Serbia's autonomy by the Great Powers at Paris. By 1867 he had managed to gain the withdrawal of all Turkish civil officials and garrisons from Serbia. Meanwhile, he helped to create the first Balkan League by negotiating alliances with Montenegro (1866), Greece (1867), and Romania (1868). With a Greater Serbia in mind, he also secretly entered into arrangements with the Albanians and with Serbs in Bosnia.

Garašanin was dismissed in 1867 because of his opposition to Michael's wish to marry his cousin Katarina Konstantinović. When Prince Milan Obrenović came to the throne in 1868, Garašanin retired from politics.

**garbā** (dance): *see* garabā.

**garbanzo:** *see* chick-pea.

**Garbett, Cyril Forster** (b. Feb. 6, 1875, Tongham, Surrey, Eng.—d. Dec. 31, 1955, York, Yorkshire), archbishop of York and ecclesiastical writer who promoted a social conscience among the membership of the Church of England by his reports on the human misery in the areas he administered as bishop, particularly London's Southwark district (1919–32).

Educated at Keble College, Oxford, Garbett was curate (1900–09) and vicar (1909–19) of a then-important Portsmouth parish before becoming bishop of Southwark (1919–32). There he restored discipline, built churches, and drew public attention to the evils of slums. Transferred to Winchester (1932–42), he felt the scope inadequate to his energies and chief interests. In 1942 he became archbishop of York, in which office his common sense, careful preparation of speeches, and gift for expressing in simple language the thoughts of laymen on matters of social, political, and religious interest made him a national figure. His books of this period, *The Claims of the Church of England* (1947), *Church and State in England* (1950), *In an Age of Revolution* (1952), and *The Church of England Today* (1953), provided a balanced account of his church.

**Garbo, Greta**, original name *GRETA LOVISA GUSTAFSSON* (b. Sept. 18, 1905, Stockholm, Sweden—d. April 15, 1990, New York, N.Y., U.S.), one of the most glamorous and popular stars of the motion pictures of the 1920s and '30s and later a legendary recluse.

Garbo was born in Stockholm to poor parents. She went to work at age 14, first as a lather girl in a barbershop, then as a clerk in a department store and as a model. In her first motion picture, *Luffar-Petter* (*Peter the Tramp*; 1922), she played a bathing beauty. From 1922 to 1924 she studied at the Royal Dramatic Theatre, Stockholm. During that period she met Mauritz Stiller, the foremost Swedish director, who gave her an important role in *Gösta Berlings Saga* (1924; "The Story of Gösta Berling"), gave her the stage name

Greta Garbo in *Camille*, 1936  
Culver Pictures

Greta Garbo, and trained her in cinema-acting techniques. In 1925, when Stiller went to the United States to work for Metro-Goldwyn-Mayer, he insisted that Garbo be given a contract also. In all, she appeared in 27 films (two in Sweden, one in Germany, and the remainder in Hollywood); the most important were *The Torrent* (1926); *Flesh and the Devil* (1927) and *Love* (1927), both with the popular leading man John Gilbert, whose name was linked with hers in a much-publicized romance; *Wild Orchids* (1929); *Anna Christie* (1930), the talking picture in which her rich, low voice was first heard; *Mata Hari* (1932); *Grand Hotel* (1932); *Queen Christina* (1933); *Anna Karenina* (1935); *Camille* (1936); and *Ninotchka* (1939), in which she displayed a surprising gift for comedy.

Garbo had, in the opinion of her directors and most critics, a perfect instinct for doing the right thing before the camera. Her talent, her great beauty, and her indifference to public opinion made her career unique in the history of the cinema.

At age 36 Garbo withdrew from the entertainment field and retired to a secluded life in New York City. In 1954 she was awarded a special Academy Award for unforgettable performances.

**BIBLIOGRAPHY.** Biographies include John Bainbridge, *Garbo* (1971); and Alexander Walker, *Garbo: A Portrait* (1980), based on MGM archives.

**Garborg, Arne Evensen**, Arne also spelled ADNE (b. Jan. 25, 1851, Time, Nor.—d. Jan. 14, 1924, Asker), novelist, poet, playwright, and essayist, one of the first great writers to show the literary possibilities of Nynorsk, which many writers wished to establish in place of the standard Dano-Norwegian literary medium. The demand for social reform was central to Garborg's life and work.

Garborg was the son of a farmer, and his father's suicide, the result of an overstrained religious conscience, made him a permanent enemy of orthodox religion, especially his narrow Pietist heritage. Like Tolstoy, he understood Christianity to mean a social and spiritual revolution. Later he moved ever further to the left and became interested in socialism, anarchism, and free love, though he attacked each when it threatened to become dogmatic.

Educated at a teachers' seminary, he taught school and edited newspapers before studying at King Frederick's University. An unusually versatile and prolific writer, Garborg established himself as one of the great writers of his time with his second novel, *Bondestudentar* (1883; "Peasant Students"), a depiction of the cultural clash between country and city life as embodied in the struggles of a peasant student living in the capital. The naturalis-

tic approach of this novel was developed in *Hjaa ho mor* (1890; "At Mother's"), winner of a German literary prize, and several further works. Garborg's masterpiece is a poetic cycle in Nynorsk, *Haugtussa* (1895; "Woman of the Underground People"), which describes a young girl's belief in the supernatural and was set to music by Edvard Grieg. Other works include translations of the *Odyssey* (1918) and of a section of the *Mahābhārata* (1921), and, for presentation in the Nynorsk theatre that he and his wife had founded, Baron Ludvig Holberg's classical comedy *Jeppe på bjerget* (1921).

**Garção, Pedro António Correia** (b. April 29, 1724, Lisbon, Port.—d. Nov. 10, 1772, Lisbon), one of Portugal's principal Neoclassical poets.

Garção studied law at Coimbra but apparently took no degree. His marriage in 1751 brought him a rich dowry, and he had a moderately lucrative government post in the India House as an administrator, but later a lawsuit reduced him to poverty. From 1760 to 1762 he edited the *Gazeta de Lisboa*. In 1756 he became a member of Arcádia Lusitana, a literary society founded to rid Portuguese poetry of the archaisms, conceits, and windy rhetoric still persisting from the 17th century. For reasons that are still obscure, Garção was arrested in April 1771 and imprisoned but was never brought to trial. He died on the day of his release.

Taking the ancient Latin poet Horace as his model, Garção adopted a classical simplicity. His sonnets and epistles reveal him as a man of good taste and good sense, devoted to his friends and possessing high ideals of conduct and of art. The *Teatro Novo* (1766; "New Theatre") attacked foreign influences in the theatre, especially Italianate ones, and the *Assembleia ou Partida* ("Meeting or Parting") satirized the social life of Lisbon. In the "Cantata de Dido," included in the latter play, he combined the spirit of classical art with perfection of form to produce one of the most celebrated 18th-century Portuguese poems.

**Garcés, Francisco (Tomás)** (b. April 12, 1738, Villa Morata del Conde, Aragon [Spain]—d. July 18, 1781, near the junction of the Colorado and Gila rivers [U.S.]), Spanish Franciscan missionary-explorer, who from 1768 to 1775 explored, alone and with Juan Bautista de Anza, commandant of the presidio at Tubac (now in Nogales, Arizona, U.S.), the Gila and Colorado rivers and sought a route from the province of Sonora to California. His attempt with Juan Díaz to found Indian missions ended in their death.

**García**, name of rulers grouped below by country and indicated by the symbol ●.

#### GALICIA

● **García II** (b. 1042?—d. March 22, 1090, Luna Castle, Aragon [Spain]), king of Galicia from 1065 to 1071. His father, Ferdinand I the Great, divided his lands among his three sons: Alfonso VI received Leon; Sancho II received Castile; and García II, the youngest, received Galicia with a portion of Portugal (1065). Despotism and suspicious, García was deprived of his kingdom by his brother Sancho II and sent into exile to the Moorish court at Seville. When Sancho II was assassinated during a fratricidal struggle with Alfonso VI and their sister Urraca, García returned from Seville. Alfonso VI, then in control, had him arrested and imprisoned in the castle at Luna (1073), never to be released. García became a figure of Castilian poetry and romance, popular in the European Middle Ages.

#### NAVARRÉ (PAMPLONA)

● **García (I)** (d. c. 860), self-styled king or chief of the Navarrese, centred in Pamplona. He is partly legendary, perhaps originally a

count and vassal of Asturias, and is said to have reconquered many towns from the Moors. His son Fortún (or Fortunio) was captured and imprisoned by the Moors in 860, and not until about 880 was he free to proclaim himself king of Pamplona. On Fortún's death (905), Sancho I Garcés reigned as the first indisputable king of Pamplona.

● **García I (or II) Sanchez** (b. 919/921—d. 970), king of Pamplona (Navarre) from 925 to 970, son of Sancho I Garcés and Queen Toda Aznar. He owed his throne to the support of his cousin 'Abd ar-Rahman III, the Umayyad caliph of Cordoba. The end of his reign was taken up with wars against the count of Castile, Fernán González. Sancho I of Leon, deposed by the Castilian, took refuge in Navarre; García took to the field and in 960 managed to capture the famous Castilian, holding him prisoner for many years. García was succeeded by his son, Sancho II Garcés.

● **García II (or III)**, byname GARCÍA THE TREMBLER, Spanish GARCÍA EL TRÉMULO (d. 1005), king of Pamplona (Navarre) and of Aragon from about 994 to about 1000, son of Sancho II Garcés. Coming to the aid of besieged Castile, García fought against the Muslim forces of Abū 'Amir al-Manšūr. Manšūr then turned his armies against Navarre (1002), burning the monastery of San Millán de la Gollá before dying unexpectedly. García died three years later and was succeeded by Sancho III Garcés, the Great.

● **García III (or IV)** (d. Sept. 1, 1054, Atapuerca, Castile [Spain]), king of Pamplona (Navarre) from 1035 to 1054. Following an old custom, Sancho III the Great divided his Spanish lands among his four sons: Ferdinand I received Castile; Gonzalo received Sobrarbe and Ribagorza (modern Huesca); Ramiro I received Aragon; and García III received the ancient patrimony of Pamplona enlarged by portions of Castile. Although García helped his brother Ferdinand I of Castile against the Leonese, Ferdinand made war on him to recover the territories of Castile, and García was killed in the Battle of Atapuerca. He was succeeded by his son Sancho IV.

● **García IV (or V)**, byname GARCÍA THE RESTORER, Spanish GARCÍA EL RESTAURADOR (d. Nov. 21, 1150, Lorca, Navarre [Spain]), king of Pamplona (Navarre) from 1134 to 1150, grandson of Sancho IV and son of El Cid's daughter Cristina and Ramiro Sánchez, lord of Monzón.

When Alfonso I of Aragon and Navarre died in 1134 and the Aragonese proclaimed the succession for his brother Ramiro II, the Navarrese rebelled and restored their own ancient line in the person of García Ramirez. García IV broke the union of Aragon and Navarre by declaring himself a vassal of Alfonso VII of Castile, "emperor" of Spain, but a year later he broke with Castile and allied himself with the Portuguese against Castile and Aragon. After Ramiro's abdication (1137), there ensued a period of warfare and intrigue among the kingdoms of Spain, ending in 1149. In spite of these wars García IV collaborated with Alfonso VII against the Muslim Almohads and took part in the conquest of Almería (1147). On his death, he was succeeded by his son Sancho VI.

**García, Anastasio Somoza**; see Somoza family.

**García, Carlos Polestico** (b. Nov. 4, 1896, Talibon, Phil.—d. June 14, 1971, Quezon City), fourth president of the Republic of the Philippines. After graduating from law school in 1923, he became, successively, a schoolteacher, representative in the Philippine Congress, governor of his province (Boh-

ol), and then (1941–53) senator. During the Japanese occupation of the Philippines in World War II, García was active in the resistance movement. He was elected vice president on the ticket of the Nacionalista Party in 1953 and was also minister of foreign affairs (1953–57). He became president of the Philippines in March 1957, upon the death of Pres. Ramon Magsaysay, and was elected to a full four-year term the same year. He maintained the strong traditional ties with the United States and sought closer relations with non-Communist Asian countries. In the election of November 1961 he was defeated by Vice Pres. Diosdado Macapagal.

**García de la Huerta, Vicente (Antonio)** (b. March 9, 1734, Zafrá, Spain—d. March 12, 1787, Madrid), playwright, poet, and critic whose Neoclassical tragedy *Raquel* (1778) was once considered the most distinguished tragic drama of 18th-century Spain.

García held a position in the Royal (later National) Library and was a political prisoner in Oran, where *Raquel* was performed. Although he was learned and translated Sophocles and Voltaire, his critical ability was not very sound. His 16-volume *Teatro español* (1785–86; "Spanish Theatre"), a collection of Spanish drama from the Golden Age (c. 1500–1650), was personal in its outlook, reflecting his particular interest in classical drama; Lope de Vega, Juan Ruiz de Alarcón, and several other important dramatists of the Golden Age were omitted from the work.

**García Gutiérrez, Antonio** (b. July 5, 1813, Chiclana, Spain—d. Aug. 26, 1884, Madrid), dramatist whose play *El trovador* (1836; "The Troubadour") was the most popular and successful drama of the Romantic period in Spain. It formed the basis for the Italian composer Giuseppe Verdi's opera *Il trovatore* (performed 1853).

**García Lorca, Federico** (b. June 5, 1898, Fuente Vaqueros, Spain—d. Aug. 18 or 19, 1936, between Vízcar and Alfacar), Spanish poet and playwright who, in a career that spanned just 19 years, resurrected and revitalized the most basic strains of Spanish poetry

and theatre. He is known primarily for his Andalusian works, including the poetry collections *Romancero gitano* (1928; *Gypsy Ballads*) and *Llanto por Ignacio Sánchez Mejías* (1935; "Lament for Ignacio Sánchez Mejías," Eng. trans. *Lament for a Bullfighter*), and the tragedies *Bodas de sangre* (1933; *Blood Wed-*

*ding*), *Yerma* (1934; Eng. trans. *Yerma*), and *La casa de Bernarda Alba* (1936; *The House of Bernarda Alba*). In the early 1930s Lorca helped inaugurate a second Golden Age of the Spanish theatre. He was executed by a Nationalist firing squad in the first months of the Spanish Civil War.

**Early years.** The eldest of four children born to a wealthy landowner and his schoolteacher wife, Lorca grew up in rural Andalusia. At about age 10 he moved with his family to Granada. He eventually enrolled in the University of Granada but took nine years to complete a bachelor's degree. Lorca's first experiments in prose, poetry, and drama reveal an intense spiritual and sexual malaise along with an adolescent devotion to such authors as Shakespeare, Goethe, and the Nicaraguan poet Rubén Darío.

In 1919 Lorca moved to the Residencia de Estudiantes in Madrid, a prestigious and socially progressive men's residence hall. It remained his home in the Spanish capital for the next decade. His fellow residents included the filmmaker Luis Buñuel and the artist Salvador Dalí, who later became a close companion.

**Early poetry and plays.** A consummate stylist, Lorca sought throughout his career to juxtapose and meld genres. His poems, plays, and prose often evoke other, chiefly popular, forms of music, art, and literature. His first book, *Impresiones y paisajes* (1918; *Impressions and Landscapes*), chronicled Lorca's sentimental response to a series of journeys through Spain, as a university student. *Libro de poemas* ("Book of Poems"), an uneven collection, followed in 1921. Both efforts disappointed Lorca and reinforced his inherent resistance to publication. Lorca preferred to perform his poems and plays, and his histrionic recitations drew innumerable admirers.

Lorca's first full-length play, *El maleficio de la mariposa* (written 1919; *The Butterfly's Evil Spell in Five Plays: Comedies and Tragi-Comedies*), a symbolist work about a lovesick cockroach, premiered in Madrid in 1920. Critics and audiences ridiculed the drama, and it closed after four performances. Lorca's next full-length play, the historical verse drama *Mariana Pineda* (written 1923; Eng. trans. *Mariana Pineda*), opened in 1927 in a production with sets by Dalí and received mixed notices.

In the early 1920s, Lorca began experimenting with short, elliptical verse forms inspired by Spanish folk song, Japanese haiku, and contemporary avant-garde poetics. He wrote a prodigious series of brief poems arranged in thematic "suites," later collected and published in 1983 under the title *Suites*. (Virtually all of Lorca's poetry—that contained in the volume under discussion and in the other Spanish volumes mentioned in this biography—has been translated in *Collected Poems*, 1991.) In 1922 Lorca collaborated with the eminent Andalusian composer Manuel de Falla on a festival of *cante jondo* ("deep song") in Granada. In a blaze of inspiration he wrote a series of poems based on songs of the Andalusian Gypsies, *Poema del cante jondo* (written 1921–25, published 1931; *Poem of the Deep Song*).

From 1925 to 1928, Lorca was passionately involved with Salvador Dalí. The intensity of their relationship led Lorca to acknowledge, if not entirely accept, his own homosexuality. At Dalí's urging, the poet began to experiment more boldly with avant-garde currents in the art world, notably surrealism. In poems such as "Oda a Salvador Dalí" (1925–26; "Ode to Salvador Dalí"), *Canciones* (written 1924, published 1926; *Songs*), and a series of abstruse prose poems, Lorca sought to create a poetry devoid of private sentiment and the "planes of reality." He joined his contemporaries in exalting Don Luis de Góngora, a 16th-century Spanish poet known for his dispassionate,

densely metaphorical verse. Lorca and his fellow poets commemorated the tricentennial of Góngora's death in 1927 and became known thereafter as the "Generation of 1927."

Meanwhile, Lorca continued to mine the popular Spanish tradition in his plays *La zapatera prodigiosa* (written 1924, premiered 1930; *The Shoemaker's Prodigious Wife*), a classic farce, and *El amor de don Perlimplín con Belisa en su jardín* (written 1925, premiered 1933; *The Love of Don Perlimplín with Belisa in Their Garden in Five Plays: Comedies and Tragi-Comedies*), a "grotesque tragedy" partially drawn from an 18th-century Spanish comic strip. Both plays reveal themes common to Lorca's work: the capriciousness of time, the destructive powers of love and death, the phantoms of identity, art, childhood, and sex.

In 1928, with Dalí's encouragement, Lorca publicly exhibited his drawings. A gifted draughtsman blessed with a startling visual imagination, Lorca produced hundreds of sketches in his lifetime.

**Romancero gitano.** The publication in 1928 of *Romancero gitano* (written 1921–27; *Gypsy Ballads*), a poetry sequence inspired by the traditional Spanish romance, or ballad, catapulted Lorca into the national spotlight. The book's first edition sold out within a year. Throughout the work's 18 ballads, Lorca combines lyrical and narrative modes in fresh ways to form what he described as a tragic "poem of Andalusia." Formally, the poems embrace the conventions of medieval Spanish balladry: a nonstanzaic construction, in medias res openings, and abrupt endings. But in their wit, objectivity, and metaphorical novelty, they are brazenly contemporary. One of the collection's most famous poems, "Ballad of the Spanish Civil Guard," reads, in part:

Los caballos negros son.  
Las herraduras son negras.  
Sobre las capas relucen  
manchas de tinta y de cera.  
Tienen, por eso no lloran,  
de plomo las calaveras.  
on el alma de charol  
vienen por la carretera.

Black are the horses,  
the horseshoes are black.  
Glistening on their capes  
are stains of ink and of wax.  
Their skulls—and this is why  
they do not cry—are cast in lead.  
They ride the roads  
with souls of patent leather.

("Ballad of the Spanish Civil Guard," excerpt. Reprinted by permission of Farrar, Straus and Giroux, LLC, from *Collected Poems by Federico García Lorca*. Translated by Will Kirkland. Translation © 1991 by Will Kirkland. Introduction and notes © 1991 by Christopher Maurer. Spanish texts © by Herederos de Federico García Lorca.)

**Later poetry and plays.** Lorca's stay in the United States and Cuba in 1929–30 yielded *Poeta en Nueva York* (published 1940; *Poet in New York*), a series of poems whose dense, at times hallucinatory images, free-verse lines, and thematic preoccupation with urban decay and social injustice mark an audacious departure from Lorca's previous work. The collection is redolent of Charles Baudelaire, Edgar Allan Poe, T.S. Eliot, and Stephen Crane and pays homage to Walt Whitman:

... hermosura viril  
que en montes de carbón, anuncios y  
ferrocarriles,  
soñabas ser un río y dormir como un río  
con aquel camarada que pondría en tu pecho  
un pequeño dolor de ignorante leopardo.  
... virile beauty,  
who among mountains of coal, billboards, and  
railroads,  
dreamed of becoming a river and sleeping like  
a river

with that comrade who would place in your breast  
the small ache of an ignorant leopard.

("Ode to Walt Whitman," excerpt, printed by permission of Farrar, Straus and Giroux, LLC, from *Poet in New York* by Federico García Lorca. Translation © 1988 by The Estate of Federico García Lorca, and Greg Simon and Steven F. White. Introduction, notes, and translation of letters © 1988 by Christopher Maurer.)

In Cuba, Lorca wrote *El público* ("The Audience"), a complex, multifaceted play, expressionist in technique, that bravely explores the nature of homosexual passion. Lorca deemed the work, which remained unproduced until 1978, "a poem to be hissed." On his return to Spain, he completed a second play aimed at rupturing the bounds of conventional dramaturgy, *Así que pasen cinco años* (1931; *Once Five Years Pass*), and he assumed the directorship of a traveling student theatre group, La Barraca (the name of makeshift wooden stalls housing puppet shows and popular fairs in Spain), sponsored by the country's progressive new Republican government.

With the 1933 premiere of his first Andalusian tragedy, *Blood Wedding*, an expressionist work that recalls ancient Greek, Renaissance, and Baroque sources, Lorca achieved his first major theatrical success and helped inaugurate the most brilliant era of Spanish theatre since the Golden Age. In 1933–34 he went to Buenos Aires, Arg., to oversee several productions of his plays and to give a lecture series. While there he befriended the Chilean poet Pablo Neruda, with whom he collaborated on a tribute to Rubén Darío. Despite his new focus on theatre, Lorca continued to write poetry. With others in the Generation of 1927, he embraced a "rehumanization" of poetry, as opposed to the "dehumanization" José Ortega y Gasset had described in his 1925 essay "The Dehumanization of Art." Eloquent evidence of Lorca's return to the personal are *Divan del Tamarit* (written 1931–1934, published 1940; "The Divan at Tamarit"), a set of love poems inspired by Arabic verse forms; *Seis poemas galegos* (written 1932–1934, published 1935; "Six Galician Poems"); and *Sonetos del amor oscuro* (written 1935, published 1984; "Sonnets of Dark Love"), an 11-sonnet sequence recalling a failed love affair. The three collections underscore Lorca's abiding insistence on the interdependence of love and death. *Divan del Tamarit* also expresses Lorca's lifelong interest in Arab-Andalusian (frequently referred to as "Moorish") culture, which he viewed as central to his identity as an Andalusian poet. He regarded the Catholic reconquest of Granada in 1492 as a tragic loss.

In 1934 Lorca responded to the goring and death of a bullfighter friend with the majestic *Lament for a Bullfighter*, a work famous for its incantatory opening refrain, "A las cinco de la tarde" ("At five in the afternoon"). The four-part poem, his longest, confirms Lorca as the greatest of Spain's elegiac poets.

A las cinco de la tarde.  
Eran las cinco en punto de la tarde.  
Un niño trajo la blanca sábana  
a las cinco de la tarde.  
Una espuerta de cal ya prevenida  
a las cinco de la tarde.  
Lo demás era muerte y sólo muerte  
a las cinco de la tarde.

At five in the afternoon.  
It was exactly five in the afternoon.  
A boy brought the white sheet  
at five in the afternoon.  
A frail of lime ready preserved  
at five in the afternoon.  
The rest was death, and death alone  
at five in the afternoon.

Lorca was at work on the unfinished *Los sueños de mi prima Aurelia* ("The Dreams of My Cousin Aurelia") and *The House of Bernarda Alba* in the summer of 1936 when

the Spanish Civil War broke out. On August 16, he was arrested in Granada by Nationalist forces, who abhorred his homosexuality and his liberal views, and imprisoned without a trial. On the night of August 18 or 19 (the precise date has never been verified), he was driven to a remote hillside outside town and shot. In 1986 the Spanish government marked the 50th anniversary of Lorca's death by erecting a monument on the site of his murder. The gesture bears witness to Lorca's stature as the most important Spanish poet and playwright of the 20th century, a man whose work continues to influence writers and artists throughout the world and to speak to readers everywhere of all that is most central to the human condition.

**BIBLIOGRAPHY.** Biographies of Lorca include Leslie Stainton, *Lorca: A Dream of Life* (1998); and Ian Gibson, *Federico García Lorca: A Life* (1989), both of which utilize primary sources and interviews. Perceptive overviews of his oeuvre are provided in Federico García Lorca, *Collected Poems*, ed. by Christopher Maurer (1991); *Poet in New York*, rev. ed., edited by Christopher Maurer, trans. by Greg Simon and Steven F. White (1998); and *Three Plays: Blood Wedding, Yerma, The House of Bernarda Alba*, trans. by Michael Dewell and Carmen Zapata (1992). Brian Morris (C.B. Morris), *Son of Andalusia: The Lyrical Landscapes of Federico García Lorca* (1997), is a brilliant study of the myriad ways the region of Andalusia infused Lorca's writing. Andrew A. Anderson, *Lorca's Late Poetry: A Critical Study* (1990), provides an astute analysis of Lorca's poetic output in the 1930s.

(L.St.)

**García Márquez, Gabriel** (b. March 6, 1928, Aracataca, Colom.), Latin-American author of novels and short stories, a central figure in the magic realism movement in Latin-American literature. He was awarded the Nobel Prize for Literature in 1982.

García Márquez, 1982  
© Lutfi Ozkok

Although born into poverty, García Márquez studied law and journalism at the National University of Colombia in Bogotá and at the University of Cartagena. He began his career as a journalist in 1948, working in Cartagena, Barranquilla, and Bogotá. In the late 1950s he was a foreign correspondent for the Bogotá daily *El Espectador* in Rome and Paris, returning to Colombia and then to Caracas as a journalist in 1958. From 1959 to 1961 he worked for the Cuban news agency La Prensa in Colombia, Havana, and New York City, and in the 1960s he worked as a screenwriter, journalist, and publicist in Mexico City. He moved to Barcelona in 1973 and in the later 1970s returned to Mexico. In the early 1980s, periodic restrictions on his travel in his native Colombia and in the United States were attributed to his avowed left-wing political views.

García Márquez began writing short stories in the late 1940s. His first major publication was *La hojarasca* (1955; *Leafstorm and Other Stories*). In this story first appears the fictional Colombian village of Macondo—the setting

of much of his later work—and his characteristic combination of realism and fantasy.

*El coronel no tiene quien le escriba* (1961), which first appeared in the Colombian magazine *Mito* in 1958, relates the story of an aged war veteran whose service remains unrecognized by the country for which he fought. It was translated together with a collection of short stories, *Los funerales de la Mamá Grande* (1962), under the title *No One Writes to the Colonel and Other Stories* (1968). During this period García Márquez also published *La mala hora* (1962; *In Evil Hour*), a story of political repression in Macondo.

It was during his first stay in Mexico that García Márquez wrote his best-known novel, *Cien años de soledad* (1967; *One Hundred Years of Solitude*), which recounts the history of Macondo and its founders, the Buendía family. It is also a history of Colombia and, on its highest level, a presentation of the myth and legend of human experience. The dense, convoluted style of this and other works recalls that of the American novelist William Faulkner.

With Mario Vargas Llosa, García Márquez produced a volume of literary criticism, *La novela en América Latina* (1968). An episode in *Cien años* gave rise to the collection of short stories titled *La increíble y triste historia de la cándida Eréndira y de su abuela desalmada* (1972; *Innocent Eréndira and Other Stories*). Another series of stories was published as *Ojos de perro azul* (1972; "Eyes of a Blue Dog"). He later wrote *El otoño del patriarca* (1975; *The Autumn of the Patriarch*), a satire on Latin-American military dictators; and *Crónica de una muerte anunciada* (1981; *Chronicle of a Death Foretold*), which examines the events surrounding a murder for honour in a Latin-American town.

García Márquez's subsequent novels were *El amor en los tiempos del cólera* (1985; *Love in the Time of Cholera*), a meditation on fidelity in romantic love; and *El general en su laberinto* (1989; *The General in His Labyrinth*), a fictional account of the Latin-American liberator Simón Bolívar during the last months of his life.

**García Moreno, Gabriel** (b. Dec. 24, 1821, Guayaquil, Ecuador—d. Aug. 6, 1875, Quito), initiator of a church-oriented dictatorship in Ecuador (1861–75). His rule, oppressive but often effective in its reformist aims, eventually cost him his life.

García Moreno early took an active role in Ecuador's turbulent politics. He became convinced that the remedy for his nation's political and economic plight was the application of moral principles by a powerful leader.

Aided by a general and former president of Ecuador, Juan José Flores, he seized power in 1860. During his two terms as president (1861–65, 1869–75), he centralized the government, reduced corruption, maintained relative peace, strengthened the economy, placed education under the Roman Catholic church, signed a concordat with the Vatican (1863), and officially dedicated Ecuador to the Sacred

García Moreno

Heart. He was assassinated by a group of young liberals.

**García Robles, Alfonso** (b. March 20, 1911, Zamora, Michoacán, Mex.—d. Sept. 2, 1991, Mexico City), Mexican diplomat and advocate of nuclear disarmament, corecipient with Alva Reimer Myrdal of Sweden of the Nobel Prize for Peace for 1982.

García Robles entered Mexico's foreign service in 1939 and was a delegate to the 1945 San Francisco Conference, at which the United Nations was founded. He subsequently worked in the UN Secretariat for several years. As director general in the Mexican Ministry of Foreign Affairs during the late 1950s, García Robles played a central role at the Law of the Sea conferences.

While serving as ambassador to Brazil, he first encountered the proposition of excluding nuclear armaments from Latin America, and, after the Cuban Missile Crisis of 1962, he persuaded the Mexican government to support such a policy. His unremitting efforts eventually led to the Treaty of Tlatelolco (1967), which committed 22 nations of Latin America to bar nuclear weapons from their territories. A year later he helped draft the Treaty on the Non-proliferation of Nuclear Weapons. He was appointed permanent representative to the Disarmament Conference in Geneva in 1977. In 1978 he served as chairman of the Mexican delegation to the UN General Assembly's special session on disarmament.

**Garcilaso DE LA VEGA** (b. 1503, Toledo, Spain—d. Oct. 14, 1536, Nice, duchy of Savoy [now in France]), the first major poet in the Golden Age of Spanish literature (c. 1500–1650).

Garcilaso was born into an aristocratic family that had been prominent in Spanish letters and politics for several centuries. Entering court life at an early age, he distinguished himself as a soldier, serving Emperor Charles V in Rhodes, Tunis, and Pavia. After a brief imprisonment in 1532 for conspiring to marry his brother's son to a prominent lady-in-waiting against the emperor's wishes, he was released into the service of the viceroy, the Marqués de Villafranca. Serving under the viceroy in southern France, he was mortally wounded in an assault on a fortified position and died several days later.

After writing poetry in rather conventional Spanish metres for a short period, Garcilaso had become acquainted with the poet Juan Boscán Almagáver, who quickly introduced him to Italianate metres, to the use of which he was further attracted by his close study of such Italian Renaissance poets as Petrarch, Giovanni Boccaccio, and Jacopo Sannazzaro. Garcilaso transformed the Italianate metres into Spanish verse of high lyric quality. His most important innovations in this regard were the verse stanzas of the *silva* and *lira* (both using combinations of 7- and 11-syllable lines), which allowed him a new concern with the analytical expression of thought and emotion. Garcilaso's major theme is the melancholy laments and misfortunes of romantic love as conventionally portrayed in pastoral poetry. He continually rewrote and polished his poetry, lifting his work high above that of his contemporaries and profoundly influencing the development of Spanish verse.

Garcilaso's small body of work—38 sonnets, 5 canciones, 3 eclogues, 2 elegies, 1 epistle, and 8 coplas (songs)—was published with that of Boscán, by the latter's widow, in 1543. These works were soon accepted as classics and largely determined the course of lyric poetry throughout Spain's Golden Age.

**Garcinia**, genus in the family Clusiaceae, with about 200 species of tropical trees found

in Asia and Australia. The best known of these species is a tropical fruit, the mangosteen (*q.v.*; *G. mangostana*). Imbe (*G. livingstonei*) has stiff leaves and small, thick-skinned, orange fruits with a juicy, acid, fragrant pulp. Rata (*G. tinctorea*) produces a peach-sized, yellow fruit with a pointed end and acid-flavoured, buttery yellow flesh. *G. spicata* is planted as an ornamental in tropical salt-spray oceanfront areas. Orange dyes are extracted from the bark of *G. xanthoehymus* and *G. cowa*.

**Gard, département**, Languedoc-Roussillon région, southern France. It is bounded on the east by the Rhône River and on the south by 10 miles (16 km) of Mediterranean coastline. The département was created from an eastern part of the historic province of Languedoc. Gard is divided into three distinct regions: (1) the northwest, on the eastern border of the Massif Central, in which the humid, wooded Cévennes heights reach 5,141 feet (1,567 m) at Aigoual Mountain; (2) the southeast, in which cereals, olives, and vines grow in the dry, hilly Garrigues region; and (3) the south, in which the summers are hot and dry and the best arable land is found, including the plain of Nîmes and some of the marshlands of the Rhône River delta. The Gard, or Gardon, River, a tributary of the Rhône, forms gorges through the Garrigues region.

Roman civilization brought economic prosperity and a wealth of monuments to the region before it was conquered by the Visigoths in the 5th century AD and ravaged by the Saracens in the 8th century. Louis IX acquired land from local monks in the 13th century and built the fortified harbour town of Aigues-Mortes (*q.v.*), from which he set out on two crusades. Other points of interest include Villeneuve-lès-Avignon, on the Rhône opposite Avignon, and Beaucaire, on the Rhône opposite Tarascon.

The département produces good wines (Côtes-du-Rhône, Tavel), and some of its ewe milk goes to Roquefort cheese factories in neighbouring Aveyron département. Industries (steel, aluminum, textiles, and electrical equipment) have been established mainly in the Nîmes area and around Alès, a former mining centre on the Gard, which is also a tourist centre. The oldest of France's atomic energy stations is in Marcoule. The département has three *arrondissements*—Nîmes, Alès, and Le Vignac—and is in the educational division of Montpellier. Area 2,260 square miles (5,853 square km). Pop. (1999) 623,125.

**Gard, Pont du** (French: "Bridge of the Gard"), giant bridge-aqueduct, a notable an-

Pont du Gard, Nîmes, Fr.

Ewing Galloway

cient Roman engineering work constructed about 19 BC to carry water to the city of Nîmes over the Gard River in southern France. Augustus' son-in-law and aide, Marcus Vipsanius Agrippa, is credited with its conception. Three tiers of arches rise to a height of 155 feet (47 m). The first tier is composed of 6 arches, from 51 to 80 feet (15 to 24 m) wide, the largest spanning the river; the second tier is composed of 11 arches of the same dimensions; the third, carrying the conduit, is composed of 35 smaller (15-foot) arches. Like many of the best Roman constructions, it was built without mortar. The structure was severely damaged in the 5th century but was restored in 1743. A highway bridge has since been added to the structure alongside its base.

Articles are alphabetized word by word,  
not letter by letter

**Garda, Lake**, Italian LAGO DI GARDA, also called **BENACO**, the largest (area 143 square miles [370 square km]) of the Italian lakes, bordering Lombardy (southwest and west), Veneto (east and southeast), and Trentino-Alto Adige (north). It is surpassed in area in the Alpine region only by Lakes Geneva and Constance. Lying at an elevation of 213 feet (65 m), the lake is 34 miles (54 km) long and 2–11 miles (3–18 km) wide, with a shoreline of 77.5 miles (125 km) and a maximum depth of 1,135 feet (346 m). Separated from the Adige River valley by the narrow ridge of Mount Baldo, the lake is fed by the Sarca River at its northern end, while the Mincio flows out toward the Po River at the southern end.

The lake was called Lacus Benacus by the classical writers Virgil, Horace, and Catullus; its name was changed when the city of Garda, elevated to a county in the early 9th century by the emperor Charlemagne, acquired dominion over the lake. The northern end belonged to Austria until 1919. Well sheltered by the Alps to the north, Lake Garda has a temperate Mediterranean climate, which makes it a popular resort area. Citrus fruits, olives, vines, laurels, oleanders, cypresses, and palms are grown on the southern and western shores, and there is fishing for eels, carp, and trout.

**Gardel, Carlos** (b. either Dec. 11, 1887, Tacuarembó, Uruguay, or Dec. 24, 1890, Toulouse, Fr.—d. June 24, 1935, Medellín, Colom.), Argentine singer and actor, celebrated throughout Latin America for his espousal of tango music.

By different accounts Gardel was the illegitimate son of a Frenchwoman or a native of Uruguay, but he was certainly in Buenos Aires by the age of six. His first formal acting roles were at the Nacional Corrientes Theatre, which also listed Don José Razzano, with whom Gardel formed a duo for many years. They played in various theatre companies, touring Argentina and other Latin-American countries and Spain. Gardel's huge popularity as an interpreter of the melancholy ballads of the tango was confirmed in the 1920s and '30s in nightclubs and motion pictures. One early picture, *Lucas de Buenos Aires* (1931; "Lights of Buenos Aires"), was filmed in Paris; but later ones were made by Paramount Pictures for the Spanish-speaking market. They include *Esperame* (1933; "Wait for Me"), *La Casa es seria* (1933; "The House Is Somber"), *Melodia de Arrabal* (1933; "Melody of Arrabal"), *Cuesta abajo* (1934; "Downhill"), *El Tango en Broadway* (1934; "The Tango on Broadway"), *Tango-Bar* (1935), *El Día que me quieras* (1935; "The Day That You Love Me"), and *Cazadores de estrellas* (1935; "Hunters of Stars").

Gardel died in a plane crash while on tour. In Buenos Aires his funeral and funeral procession in a horse-drawn carriage were wit-

nessed by tens of thousands of Argentines. Like Rudolf Valentino's, his tomb became an object of popular pilgrimage.

**Garden, Mary** (b. Feb. 20, 1874, Aberdeen, Scot.—d. Jan. 3, 1967, Aberdeen), soprano famous for her vivid operatic portrayals. She was noted for her acting as well as her singing, and was an important figure in American opera.

Garden studied voice as a child in Chicago and was later sent to Paris to study under the noted teacher Mathilde Marchesi. Her spur-of-the-moment debut as a last-minute replacement in Gustave Charpentier's *Louise* (Paris, 1900) established her reputation. She made her American debut in New York City in 1907 as Massenet's *Thaïs*.

Garden began a long association with Chicago opera in 1910 and was influential in retaining French opera in the repertory there. She was director of the Chicago Opera Association in 1921–22, a financially disastrous season. She retired from the stage in 1930 but remained active in musical circles until the mid-1950s.

Debussy chose her to create the part of *Mélisande* in his *Pelléas et Mélisande* (1902), and this ethereal role became permanently identified with her. Massenet rewrote the tenor lead in *Le Jongleur de Notre Dame* (*The Juggler of Notre Dame*) for her; this portrayal probably inspired the role of Octavian in Richard

Mary Garden as *Mélisande*  
The Bettmann Archive

Strauss's *Der Rosenkavalier*. Strauss's *Salome* was one of her most celebrated roles, and her performance of the "dance of the seven veils" caused a scandal in Chicago. With Louis Biancolli she wrote an autobiography, *Mary Garden's Story* (1951).

**Garden carpet**, floor covering designed as a Persian garden seen from directly above. The design consists of a central watercourse, with tributary canals of various sizes, interrupted by islands or by tanks containing waterfowl and fishes, lined by avenues of stylized small trees and shrubs that surround flower plots, and often shaded by great plane trees.

The earliest, best examples of Garden carpets, dating from the late 16th or early 17th century, are in museums at Jaipur in India and at Glasgow. They were apparently made at Kerman and share characteristics of weave and colour with Vase carpets. A later, simplified group of Garden carpets shows the bold, varied coloration of Kurdistan, together with small Kurdish details. In the early 19th century the design in certain Kurdish pieces degenerated into a mere checkerboard of flower beds. The most celebrated Persian Garden carpet, the Spring of Khosrow Carpet, made for the palace of a 6th-century Sāsānian king, is little more than a legend, for the carpet itself has not survived, and descriptions of it

Persian Garden carpet, 18th century; in the Metropolitan Museum of Art, New York City

by Arab writers do not disclose its technique. Certain Turkmen or Shirvan rugs have also been described as Garden rugs. In a broad sense, every Near Eastern floral carpet or rug actually represents, in its own fashion, a garden—especially if it is filled with prancing animals.

**Garden City**, city, seat (1883) of Finney county, southwestern Kansas, U.S., lying on the Arkansas River. Founded in 1878, it acquired its name through the suggestion of a visitor who admired a local flower garden. The city is the centre of an irrigated agricultural area of the Arkansas River Valley known for its alfalfa, wheat, grain sorghums, sugar beets, and livestock. The city's chief industries include meat-packing, food processing, machine shops, and the manufacture of brick and tile. Natural gas and oil are produced in the vicinity. Garden City Community College was established in 1919. Finnup Park includes the state's largest zoo and other recreational facilities; a state game refuge nearby protects a large buffalo herd. Inc. city, 1883. Pop. (1990) 24,097.

**Garden City**, residential village in Hempstead town (township), Nassau county, New York, U.S., on western Long Island. One of the nation's first planned communities, it was the aspiration of Alexander T. Stewart, who bought a 7,000-ac (2,800-ha) tract of land there in 1869. His heirs founded the Garden City Company, which developed and guided the community until its incorporation as a village in 1919. Distinguished for its handsome residential areas and garden atmosphere, it is the site of the English Gothic Cathedral of the Incarnation (seat of the Episcopal diocese of Long Island) and of the George Mercer Jr. Memorial School of Theology. Adelphi University (founded 1896 in Brooklyn) was relocated there in 1929. The village has established a reputation as a publishing and printing centre. Nearby Roosevelt Field, now a shopping centre, was the starting point for Charles A. Lindbergh's historic transatlantic flight in 1927. Nassau Community College (founded 1959) is in Garden City. Pop. (1990) 21,686.

**garden city**, the ideal of a planned residential community, as devised by the English town planner Ebenezer Howard (q.v.) and

promoted by him in *Tomorrow: A Peaceful Path to Social Reform* (1898). Howard's plan for garden cities was a response to the need for improvement in the quality of urban life, which had become marred by overcrowding and congestion due to uncontrolled growth since the Industrial Revolution.

Howard's solution to the related problems of rural depopulation and the runaway growth of great towns and cities was the creation of a series of small, planned cities that would combine the amenities of urban life with the ready access to nature typical of rural environments. The main features of Howard's scheme were: (1) the purchase of a large area of agricultural land within a ring fence; (2) the planning of a compact town surrounded by a wide rural belt; (3) the accommodation of residents, industry, and agriculture within the town; (4) the limitation of the extent of the town and prevention of encroachment upon the rural belt; and (5) the natural rise in land values to be used for the town's own general welfare.

Howard's ideal garden city would be located on a 6,000-acre tract of land currently used for agriculture purposes only. It would be privately owned by a small group of individuals; this company, in retaining ownership, would retain control of land use. Revenue, to pay off the mortgage and to fund city services, would be raised solely by rents. Private industry would be encouraged to rent and to use space in the town. Only a fraction of the tract's land would be built upon by the town's 30,000 inhabitants; the rest would be used for agricultural and recreational purposes.

At the centre of the city would lay a garden ringed with the civic and cultural complex including the city hall, a concert hall, museum, theatre, library, and hospital. Six broad main avenues would radiate from this centre. Concentric to this urban core would be a park, a combination shopping centre and conservatory, a residential area, and then, at the outer edge, industry. Traffic would move along avenues extending along the radii and concentric boulevards.

Howard stressed that the actual placement and planning of such a town would be governed by its site. In 1903 he had the pleasure of seeing his plan realized. A garden city called Letchworth was developed about 30 miles north of London in Hertfordshire, Eng. It succeeded according to the guidelines that he had laid down, and in 1920 a second, Welwyn Garden City, was established nearby. Howard's concept of interrelating country and city in a planned city of predetermined size has enjoyed wide popularity in the planning of subsequent new towns. His emphasis on greenbelt areas and controlled population densities has become an integral part of suburban and city planning as well.

Aerial view of Letchworth, Hertfordshire, the first garden city in England, founded in 1903.

Aerofilms Limited

**garden cress**, also called UPLAND CRESS (*Lepidium sativum*), North African annual herb, of the mustard family (Brassicaceae), often cultivated as a salad plant for the peppery basal leaves of the young plants. Some varieties have golden leaves. Garden cress bears

Garden cress (*Lepidium sativum*)  
Roger & Joy Spurr—Bruce Coleman Inc

white, occasionally reddish, flowers. The flattened seedpod is deeply notched, has a narrow wing, and contains one seed.

**Garden Island**, Australian island in the Indian Ocean, just off the southwest coast of Western Australia, 30 mi (48 km) southwest of Perth. With Green and Penguin islands, it shelters Cockburn Sound (east) and the approaches to the ports of Fremantle, Kwinana, and Rockingham. Measuring 6 mi by 1 mi, it has an area of 2,338 ac (946 ha) and is generally sandy and thickly wooded, rising to 211 ft (65 m) in hills along its western shore. It was sighted in 1801 by the French navigator Capt. J. Hamelin, who called it Île de Bauche. In 1829 a British colony expedition, prevented from landing on the mainland by rough seas, landed on the island instead and there proclaimed the colony. In that same year, Lieut. Gov. Capt. James Stirling planted seeds for a garden, whence the island's name. This settlement was short-lived, and the island was abandoned for Fremantle. Later in the century, a large bay on its southeast coast was utilized for careening (beaching ships for repairs). During World War II the island was a secret military training base, and in 1978 a naval support facility, HMAS "Stirling," was commissioned. There has been extensive resort development, with ferry services from Perth and Rockingham. A causeway (1972) joins the island with the mainland.

**Garden of** —: see *under* substantive word (e.g., Eden, Garden of).

**garden pepper** (*Capsicum*): see *pepper*.

**garden spider**, also called CROSS SPIDER (*Araneus diadematus*) member of the family Araneidae (suborder Labidognatha), characterized by white marks arranged in the form of a cross on the abdomen. A fairly common species, the garden spider occurs throughout the Northern Hemisphere and is often found in grassy areas and gardens, where it builds an orb-shaped web on low shrubs. The adult

spider lives in a retreat, usually a curled up leaf connected to the web by a "signal" thread, which vibrates when prey lands in the web. In general, garden spiders mature in the summer. Eggs laid in the autumn hatch the following spring, and the newly emerged spiderlings spin an irregular mass of silk in which they cluster in a ball for several days. When disturbed they rush out in all directions but soon recluster if left alone. They overwinter as juveniles and mature the following summer. See also orb weaver.

**garden tapestry**: see *verdure tapestry*.

**Gardenia**, genus of ornamental shrubs and trees of the madder family (Rubiaceae), containing about 200 species native to tropical and subtropical Africa and Asia. Gardenias

Cape jasmine (*Gardenia jasminoides*)  
A to Z Botanical Collection—EB Inc

have white or yellow tubular flowers, evergreen leaves, and large, berrylike fruits containing a sticky, orange pulp.

Cape jasmine (*G. jasminoides*), native to China, is the fragrant species sold by florists.

**gardening**, the laying out and care of a plot of ground devoted partially or wholly to the growing of plants such as herbs, fruits, flowers, or vegetables. Gardening can be considered both as an art, concerned with arranging plants harmoniously in their surroundings, and as a science, encompassing the principles and techniques of plant cultivation.

A brief treatment of gardening follows. For full treatment, see MACROPAEDIA: Gardening and Horticulture.

Planting and tending a garden next to a dwelling place is practiced not only for the spot of beauty, repose, and seclusion it creates, or for the food it provides, but also for the feelings of relaxation, anticipation, and contentment gained from the work involved. Many garden plants are grown in conditions widely different from their natural environments and have been selectively bred for generations. Gardening therefore requires protecting them from naturally growing weeds and cultivating them according to methods derived both from science and from practical experience under local conditions.

Small home gardens became prevalent in the 19th century. Individual plants and flowers attracted increasing interest, and growers started to specialize, introduce exotic species, and compete in exhibitions. Private gardens have become smaller and less formal than those of earlier times. They may occupy extensive areas surrounding the house or may be as small as a window box or some pots on a windowsill. Labour-saving tools and new discoveries in plant physiology and pest control have encouraged the spread of horticulture both as a profession and as a relaxation and hobby.

Designs for a garden area often incorporate a boundary (for example, a fence, wall, or

hedge), paths, seats, and some focal point, such as a pool or piece of sculpture. The more or less permanent elements of a garden may include lawn, shrubs, vines, and trees. The lawn usually consists of grass, kept shorn close to the ground. Nongrass lawns may be planted with some variety of low-growing creeping plant. Shrubs and bushes growing up to about 20 feet (6 metres) require little labour, and some flowering varieties bloom for extended periods. Vines can soften the sharp lines of buildings and fences, provide shade over arbours, or cover slopes and terraces. Trees, furnishing protection and interest, have a range of sizes, shapes, and colours broad enough to suit any garden scheme. Transitory elements in a garden include the herbaceous plants—annuals, biennials, and perennials—which die down each year, and the bulbous plants, which survive seasons unfavourable for growth and from which a new stem arises annually.

The style of a garden depends on how it is laid out, where it is situated, and what plants are grown. A well-designed flower garden displays blends and contrasts of colours and forms. Shrubs and trees are placed first and the spaces for herbaceous plants and bulbs arranged around them. The design may include areas of blooms for both the summer and the spring. Woodland gardens have a less formal style. Trees are thinned but left in irregular groups; paths are winding; plants are those that grow naturally in the woods.

Rock gardens are planned to look like a natural part of a rocky slope. The rocks, mainly of sandstone or limestone, are arranged to provide various exposures for sun-tolerant and shade-tolerant plants. A water garden may have a formal pool and fountains, or it may consist of an irregular-shaped pool containing water lilies and other vegetation surrounded by boggy soil for moisture-tolerant plants. Vegetable and herb gardens require sunny locations, and vegetable crops are most successful when they are rotated every three years or so. Rooftop gardens, window boxes, and indoor plants are increasingly popular in urban areas and can thrive well with the right choice of plants.

Soil is the basic factor in plant cultivation. It consists largely of mineral particles derived from the breakdown of rocks and other substances and also contains organic matter. Plant roots penetrate spaces between the particles where air, water, and microorganisms circulate. Ideal garden soil is a clay and sand mixture, rich in organic materials and of the proper degree of acidity or alkalinity for the plants to be grown.

The three chief elements that plants need for growth (other than light and water) are nitrogen, potassium, and phosphorus. Animal manures or composts of decayed plant matter can supply most growth requirements to the soil. Thorough watering is essential, furnishing the plants with needed moisture and making minerals available in solution. Many plants can withstand temperatures below freezing, but less hardy plants may have to be protected from cold weather by wrapping them or covering them with a mulch of leaves, soil, or ashes. Glass frames provide greater protection, and heated greenhouses permit plants to grow throughout the winter.

Trees and shrubs sometimes require pruning—cutting off branches or shoots—to restrict the plant to a desired size and shape. Shrubs may flower more abundantly after pruning, and pruned fruit trees often yield larger and better fruit. New plants can be propagated either from seeds or from a part of the parent plant. Seeds of vegetables and annual plants are usually sown in the spring. Trees and bushes can be produced by a variety of propagation methods from parent shoots or buds.

Two essential gardening tasks are the control of weeds and the protection of plants from

pests and diseases. Chemical and biological weed killers can be effective, but hoeing and hand weeding are often necessary. Garden pests include some insects and mites as well as a number of mammals; diseases may be caused by fungi, bacteria, or viruses. Keeping a clean, well-ventilated garden and rotating crops can help to prevent some of these problems. Chemical control is widely used, though with some long-term environmental risks.

Gardens in the world's temperate zones are generally more varied and successful than those of the tropics. Tropical gardens are able to maintain fewer herbaceous plants, and their dominant features tend to be flowering trees, shrubs, and climbers. In cooler climates the winter resting season enables many different plants and trees to thrive year after year.

**Gardeyz**, also spelled GARDĒZ, town, eastern Afghanistan, located on a high plain at an elevation of 7,550 feet (2,300 m), near the Jolgeh-ye Janūbi River. Gardeyz is a trade centre for lumber produced in the area and is connected by roads with Kābul, the nation's capital, 60 miles (100 km) north, and Ghazni. Old trade routes lead from the town to northwestern Pakistan. Pop. (1982 est.) 10,040.

**Gardie, Jacob Pontusson, Greve De la:** see De la Gardie, Jacob Pontusson, Greve.

**Gardie, Magnus Gabriel, Greve De la:** see De la Gardie, Magnus Gabriel, Greve.

**Gardiner**, city, Kennebec county, southwestern Maine, U.S., on the Kennebec River (head of navigation), just south of Augusta and bounding Farmingdale, West Gardiner, and Richmond. Founded in 1754 by Sylvester Gardiner as Gardinerstown Plantation, it was set off from Pittston in 1760. Incorporated as a town in 1803, it had by 1850, when it became a city, acquired shoe factories, paper mills, and woodworking shops. One of the first workable steam automobiles in America was built there in 1858. It was the boyhood home of the poet Edwin Arlington Robinson (1869–1935) and is considered to be the "Tilbury Town" of his poems. Laura E. Richards (1850–1943) lived in Gardiner, where she wrote many of her novels including *Captain January* (1890). Pop. (1990) 6,746.

**Gardiner, James Garfield** (b. Nov. 30, 1883, Farquhar, Ont., Can.—d. Jan. 12, 1962, Balcarres, Sask.), Canadian statesman who twice served as premier of Saskatchewan (1926–29 and 1934–35).

After working on a farm in Manitoba from 1901, Gardiner in 1904 moved to Saskatchewan, where he became a schoolteacher and principal. He became a Liberal member of the Saskatchewan Legislative Assembly in 1914 and sat until 1935. After being appointed to the provincial Cabinet in 1922, he succeeded C.A. Dunning as premier in 1926. His party lost the 1929 election but returned in 1934, with Gardiner again as premier.

He resigned as premier the following year to become federal minister of agriculture and was elected to the dominion House of Commons for Melville. Gardiner was minister of agriculture during W.L. Mackenzie King's and Louis Saint Laurent's ministries. He dealt with federal agricultural assistance during the Great Depression of the 1930s and with problems relating to World War II (1939–45). In 1947 he was appointed to the Imperial Privy Council and made an unsuccessful attempt to replace King as Liberal leader. Re-elected to the House in 1957, Gardiner resigned his portfolio when the Liberal ministry resigned.

**Gardiner, Samuel Rawson** (b. March 4, 1829, Ropley, near Alresford, Hampshire, Eng.—d. Feb. 23, 1902, Sevenoaks, Kent), English historian, whose career was dedicated to the study of the English Civil Wars.

He was educated at Winchester and Christ

Church, Oxford, and for some years was a member of the Irvingite Church. From 1871 to 1885 he taught at King's College, London, becoming professor of modern history there in 1876. He was elected fellow of All Souls College, Oxford, in 1884 and of Merton College in 1892 but declined the regius professorship in 1894.

His researches among manuscript collections at Simancas, Venice, Rome, Brussels, and Paris, as well as in England, gave unrivalled authority to the monumental undertaking that took shape between 1863 and 1900. Its principal stages were the *History of England From the Accession of James I to the Outbreak of the Civil War, 1603–1642*, 10 vol. (1883–84); *History of the Great Civil War, 1642–1649*, 3 vol. (1886), 4 vol. (1893); and *History of the Commonwealth and Protectorate, 1649–1660*, 4 vol. (1903). In analyzing the cause of the Civil War, he showed keen perception of individual motives as well as broad understanding of the material factors underlying political conduct. He was ready to credit England with a sense of nationhood wider and deeper than any provided for by the mere forms of government, and this gave drama to his otherwise unadorned chronicle. Inconsistencies and misinterpretations may be found, but the authority of his *History of England* continues to command respect little short of that usually reserved for original sources.

Among the most noteworthy of his separate works are *Prince Charles and the Spanish Marriage*, 2 vol. (1869); *Outline of English History* (1st ed., 1881; later ed., 1919); *Student's History of England*, 2 vol. (1st ed., 1890–91; later ed., 3 vol., 1920); *What Gunpowder Plot Was* (1897); and *Oliver Cromwell* (1901). His edition of *Constitutional Documents of the Puritan Revolution 1628–1660* (1889) continues to be widely used. He also edited collections of papers for the Camden Society and from 1891 was editor of the *English Historical Review*.

**Gardiner, Stephen** (b. c. 1482, Bury St. Edmunds, Suffolk, Eng.—d. Nov. 12, 1555, London), English bishop and statesman, a leading exponent of conservatism in the first generation of the English Reformation. Although he supported the antipapal policies of King Henry VIII (ruled 1509–47), Gardiner rejected Protestant doctrine and ultimately backed the severe Roman Catholicism of Queen Mary I (ruled 1553–58).

The son of a clothmaker, he obtained his doctorate in civil and canon law from the University of Cambridge in 1520–21. Throughout a busy public life he maintained ties to Cambridge, serving as master of Trinity 1525–49 and 1553–55. Gardiner became, in 1525, secretary to Henry VIII's chief minister, Cardinal Wolsey, and in 1528–29 he was sent on missions to Pope Clement VII to negotiate for the annulment of Henry's marriage to Catherine of Aragon—the issue that was to cause Henry to break with Rome and declare himself head of the English Church. As a reward for his services Gardiner was made Henry's principal secretary in 1529 and bishop of Winchester, the wealthiest see in England, in September 1531.

Gardiner, however, failed to earn the King's trust; in 1532 Henry bypassed him to appoint as his archbishop of Canterbury the obscure Thomas Cranmer, who was to become a renowned Protestant reformer. Two years later Henry's chief adviser, Thomas Cromwell, eased Gardiner out of his secretaryship. Thus the Bishop became the inveterate enemy of both Cromwell and Cranmer. Gardiner recovered some favour at court by publishing his *Episcopi de vera obedientia oratio* (1535; "Bishop's Speech on True Obedience"), a treatise attacking the papacy and upholding royal supremacy over the Church of England. In

1539, however, he led the conservative reaction that, through the Act of Six Articles, required all Englishmen to abide by the main tenets of Roman Catholic doctrine. Gardiner and his sometime colleague Thomas Howard, 3rd duke of Norfolk, had a hand in bringing about Cromwell's downfall in June 1540, and he then succeeded Cromwell as chancellor of Cambridge. Thereafter Henry kept Gardiner on his royal council in order to counter the Protestant sympathies of some of his other advisers, but he would not allow the Bishop to bring Cranmer to trial on charges of heresy. Gardiner was also frustrated in his campaign to destroy Queen Catherine Parr, and Henry did not name him to the council of regency for his son Edward.

During the rapid advance toward Protestantism that took place upon the accession of Edward VI, Gardiner was sent to prison for refusing to enforce Cranmer's Reformist injunctions. Although released in January 1548, he was imprisoned in the Tower of London in June and remained there until Edward's death (on July 6, 1553), being deprived of his bishopric late in 1550.

After the Catholic Mary I ascended the throne, Gardiner was restored to his see in August 1553 and appointed lord chancellor. Although he had become, in effect, chief minister of the realm, he was in a difficult position because he felt out of step in a court increasingly oriented toward Rome and—after Mary wed the Holy Roman emperor Charles V's son Philip (King Philip II of Spain, 1556–98)—by Spain. Gardiner approved the severe persecution of Protestants that began early in 1554, but to his credit he tried unsuccessfully to save Cranmer and others from the stake. He died two years before the persecutions ended. Gardiner had earned distinction for his legal and administrative talents; he was a powerful churchman but not a great spiritual leader. See J.A. Muller, *Stephen Gardiner and the Tudor Reaction* (1926).

**Gardner, Alexander** (b. Oct. 17, 1821, Paisley, Renfrew, Scot.—d. 1882, Washington, D.C.), photographer of the American Civil War and of the American West during the latter part of the 19th century.

Gardner probably came to the United States in 1856, when he was hired by the photographer Mathew B. Brady as a portrait photographer. Two years later, Gardner opened a portrait studio for Brady in Washington, which was so successful that it helped to support Brady's more extravagant New York studio.

When the American Civil War erupted in 1861, Gardner assisted Brady in his effort to make a complete photographic record of the conflict. Brady, however, refused to give Gardner public credit for his work. Gardner, therefore, left Brady in 1863, opened a portrait gallery in Washington, and continued to photograph the hostilities on his own. His photographs "President Lincoln on the Battlefield of Antietam" (1862) and "Home of a Rebel Sharpshooter, Gettysburg" (1863) and his portraits of Abraham Lincoln are among the best known photographs of the war period. *Gardner's Photographic Sketch Book of the Civil War*, a two-volume collection of 100 original prints, was published in 1866. When Brady petitioned Congress to buy his photographs of the war, Gardner presented a rival petition, claiming that it was he, not Brady, who had originated the idea of providing the nation with a photographic history of the conflict. Congress eventually bought both collections.

In 1867 Gardner became the official photographer for the Union Pacific Railroad. Pri-

marily active in Kansas, he photographed the building of the railroad and the new settlements that grew up near it. He also compiled

"Home of a Rebel Sharpshooter, Gettysburg," by Alexander Gardner, 1863  
George Eastman House Collection

valuable photographic documentation of the Indians of the Great Plains. Returning to Washington, he gradually lost interest in photography and devoted the rest of his life to philanthropy.

**Gardner, Ava (Lavinia)** (b. Dec. 24, 1922, Smithfield, N.C., U.S.—d. Jan. 25, 1990, London, Eng.), American motion-picture actress of the 1940s and '50s.

The daughter of a poor Southern sharecropper, Gardner attended local school and at age 18 went to New York City, where she took a screen test. Her extraordinary beauty won her a contract with Metro-Goldwyn-Mayer studios. In Hollywood she received acting and diction lessons while playing bit roles in a score of minor motion pictures in the 1940s. Her first important role was opposite Burt Lancaster in *The Killers* (1946), and she went on to starring roles in such films as *The Hucksters* (1947), *One Touch of Venus* (1948), *Show Boat* (1951), *The Snows of Kilimanjaro* (1952), and *The Barefoot Contessa* (1954). Her husky voice and seductive personal presence had made her one of the best-known American actresses by the early 1950s. But Gardner was not content to be typecast as a "sex symbol," and her sensitive characterizations in such pictures as *Mogambo* (1953), *Bhowani Junction* (1956), *On the Beach* (1959), and *The Night of the Iguana* (1964) received critical praise. She was nominated for an Academy Award in 1953 for her performance opposite Clark Gable in *Mogambo*.

Gardner left Metro-Goldwyn-Mayer in 1958 and became an independent actress. She continued to appear in films through the 1960s and '70s, though usually in less-important roles than before. Gardner's typical screen persona was that of an earthy, free-spirited, and irreverent woman of the world. She was married three times, to the actor Mickey Rooney, the bandleader Artie Shaw, and the singer Frank Sinatra.

**Gardner, Erle Stanley** (b. July 17, 1889, Malden, Mass., U.S.—d. March 11, 1970, Temecula, Calif.). American author and lawyer who wrote nearly 100 detective and mystery novels that sold more than 1,000,000 copies each, making him easily the best-selling American writer of his time. His best-known works centre on the lawyer-detective Perry Mason.

The son of a mining engineer, Gardner

traveled extensively with his family throughout childhood. He dropped out of Valparaiso University, Valparaiso, Ind., after a brief time and settled in California, where he worked as a typist in a law firm. After three years he was admitted to the California bar (1911) and

began defending poor Chinese and Mexicans as well as other clients. His interest in the friendless and unjustly accused was lifelong and led to his founding of The Court of Last Resort in the 1940s, an organization dedicated to helping men imprisoned unjustly.

While practicing trial law in Ventura, Calif., he began writing for the pulp magazines popular at that time, creating accurate courtroom scenes and brilliant legal maneuvers resembling his own legal tactics. By 1932 he was writing more than 200,000 words a month while still working two days a week in his

Erle Stanley Gardner  
Brown Brothers

law practice. With the successful publication of the first Perry Mason detective stories, *The Case of the Velvet Claws* (1933) and *The Case of the Sulky Girl* (1933), however, he gave up the law. Eighty Perry Mason novels followed. Gardner later supervised the adaptation of the Perry Mason stories for radio, television, and motion pictures.

A second series of books, built around Doug Selby, a virtuous crusading district attorney, all had titles beginning "The D.A. . . .": *The D.A. Calls It Murder* (1937) and *The D.A. Goes to Trial* (1940). A third series, written under the pseudonym A.A. Fair, dealt with the adventures of the fat, middle-aged, greedy private detective Bertha Cool and the knowledgeable legalist Donald Lam.

**Gardner, Percy** (b. Nov. 24, 1846, London, Eng.—d. July 17, 1937, Oxford, Oxfordshire), English archaeologist who was noted for his contributions to the study of Greek numismatics.

Gardner was a prolific writer and lecturer on numismatics, Greek art, and religious subjects,

as well as a gifted teacher. He was educated at Christ's College, Cambridge, and while a member of the department of coins and medals at the British Museum, London, he contributed several volumes to the museum's *Catalogue of Greek Coins*. In 1880 he became a professor of archaeology at the University of Cambridge and the first editor of the *Journal of Hellenic Studies*, which he cofounded. In 1887 he transferred to the University of Oxford, where he taught for 38 years.

Among his best-known works are *The Types of Greek Coins* (1883), important for demonstrating the ways in which coinage reflects the history of Greek cities and the development of Greek art, *Samos and Samian Coins* (1882), and *New Chapters in Greek Art* (1926). His *Principles of Greek Art* (1913), an elaboration of *Grammar of Greek Art* (1905), became a standard introduction.

**Gardner Museum**, in full ISABELLA STEWART GARDNER MUSEUM, home and art collection, located in Fenway Court, Boston, Mass., U.S. The building, designed in the style of a 15th-century Venetian palace and built between 1899 and 1903, houses a collection that includes Oriental art and Classical, medieval, and Renaissance sculpture and decorative arts, as well as masterpieces of European painting from the Middle Ages to the late 19th century. Many of the art objects in the collection were acquired for Isabella Stewart Gardner by the famed connoisseur Bernard Berenson. The arrangement of the rooms has remained unchanged, and there have been no additions to the collection since Mrs. Gardner's death in 1924, in accordance with the terms of her will.

**garefowl** (bird): *see* great auk.

**Garfield, James A(ram)** (b. Nov. 19, 1831, near Orange, Ohio, U.S.—d. Sept. 19, 1881, Elberon, N.J.), 20th president of the United States (March 4–Sept. 19, 1881). When he was shot and rendered unconscious soon after taking office, serious constitutional questions arose concerning who should properly perform the functions of the presidency.

Garfield's father died in 1833, leaving the family in poverty. His mother continued to run the family's small farm and to see that her children went to the neighbourhood school.

James Garfield, 1880

By courtesy of the Library of Congress, Washington, D.C.

Garfield attended Western Reserve Eclectic Institute at Hiram, Ohio, and was graduated from Williams College (1856). He then returned to the academy in Ohio as a teacher and later as principal.

An advocate of free-soil principles, Garfield soon became a supporter of the newly organized Republican Party, and in 1859 he was elected to the Ohio legislature. During

the American Civil War he helped recruit the 42nd Ohio Volunteer Infantry and became its colonel. He fought at Shiloh (April 1862), served as chief of staff in the Army of the Cumberland, saw action at Chickamauga (September 1863), and emerged as a major general of volunteers.

In 1862 he was elected to the U.S. House of Representatives, where he served until 1880. As chairman of the House Committee on Appropriations, he became an expert on fiscal matters, advocated a high protective tariff, and, as a Radical Republican, sought a firm policy of Reconstruction for the South. In 1880 the Ohio legislature elected him to the U.S. Senate.

At the Republican presidential convention the same year in Chicago, the delegates were sharply divided between supporters of James G. Blaine and Ulysses S. Grant. Garfield, present as the chairman of the Ohio delegation, led a coalition of anti-Grant delegates who succeeded in rescinding the unit rule, by which a majority of delegates from a state could cast the state's entire vote. This rule change doomed Grant's candidacy. He led all other candidates for 35 ballots, but failed to command a majority; and on the 36th ballot the nomination went to Garfield. In November, with a popular plurality of less than 50,000 votes, Garfield was elected.

On July 2, 1881, after only four months in office, Garfield was shot at the railroad station in Washington, D.C., by Charles J. Guiteau, a disappointed office seeker. For 80 days the president lay ill and performed only one official act—the signing of an extradition paper. It was generally agreed that, in such cases, the vice president was empowered by the Constitution to assume the powers and duties of the office of president. But should he serve merely as acting president until Garfield recovered, or would he receive the office itself and thus displace his predecessor? Because of an ambiguity in the Constitution, opinion was divided, and, since Congress was not in session, the problem could not be debated there. On Sept. 2, 1881, the matter came before a Cabinet meeting where it was finally agreed that no action would be taken without first consulting Garfield. But in the opinion of the doctors this was impossible, and no further action was taken before the death of the president on September 19.

**garfish**, European species of needlefish (*q.v.*).

**Gargallo (y Catalán), Pablo** (b. 1881, Mailla, Spain—d. Dec. 28, 1934, Reus), 20th-century Spanish sculptor, among the first to work in iron; he introduced Pablo Picasso to metal sculpture. Although he used the Cubist concepts that he learned from Picasso to focus attention on the human figure, he never adopted complete abstraction.

After studying drawing and sculpture in Barcelona, Gargallo won a scholarship to continue his studies in Paris but was forced to return shortly thereafter to support his widowed mother and her family. Returning to Paris in 1911, he met Amedeo Modigliani, Juan Gris, Guillaume Apollinaire, and other French artists and saw Picasso's Cubist paintings. He returned to Barcelona in 1914 and in 1917 began to teach at the Academy of Arts, only to return once more to Paris, in 1924. After his death he was honoured with four major posthumous exhibitions, in 1935 at Madrid and in Paris, in 1947 in Paris, and in 1955 at the Venice Biennale.

Gargallo achieved recognition in the 1920s for his figure sculptures, constructed of thin leaves of metal. Works such as "The Prophet" (1930) and "Picador" (1928) are examples of

"The Prophet," bronze statue by Pablo Gargallo, 1930; in the National Museum of Modern Art, Paris

his emphasis on the human figure and his use of Cubist techniques to achieve realism rather than abstraction.

**Gargano, Italian PROMONTORIO DEL GARGANO**, also called MONTE GARGANO, mountainous promontory jutting into the Adriatic Sea from the east coast of Italy, in Foggia province, Puglia (Apulia) region. Called the "spur" of the Italian "boot" (peninsula), it is 40 miles (65 km) long and 25 miles (40 km) at its widest, with an area of 778 square miles (2,015 square km). The peninsula is composed entirely of limestone, surrounded by terraces of various geologic periods, and rises to 3,494 feet (1,065 m) at Mount Calvo. The north coast has splendid citrus and olive groves and vineyards along the shore; the southern slopes, facing the Foggia plain, are known for their heavy red wines. The oak forests, famous in ancient times, have largely been cut, and only naked bedrock remains over much of the interior of the Gargano; the Umbra Forest (mainly beech) is the most famous of the few surviving forest preserves.

Vieste, on the eastern tip, and Manfredonia (*q.v.*), on the south coast, are the main seaside settlements. Monte Sant'Angelo (*q.v.*), an ancient pilgrimage centre, and San Giovanni Rotondo, near which bauxite is mined, are the largest towns of the interior.

**Gargas**, cave in southern France containing important examples of Late Paleolithic mural art, paintings and engravings dating from the Aurignacian Period, the oldest phase of European Stone Age art. The cave and its decoration were discovered in 1887. Many "macaroni," or finger tracings, appear on the clay walls and ceiling of the cave; some are simply tangled lines, representing the most ancient attempts at art, and some are primitive but lively outlines of animal forms. From a somewhat later stage are a number of engraved animal pictures cut with a sharp tool into the rock of the cave: wild horses, ibex, stags, oxen, bison, and mammoths were rendered in a vigorous naturalism that is typical of Aurignacian art and probably functioned as magical images relating to hunting and animal fertility. The distinctive feature of the decoration at Gargas, however, is the large number of silhouettes of human hands painted on the walls of the cave. These are "negative imprints" of real hands, achieved by blowing paint around and between the fingers while the hand is held pressed to the wall surface. Hand

silhouettes of this type are the oldest form of painting known, the earliest examples dating from about 30,000 bc. They occur throughout the cave art of France and Spain, both as "negative" and as "positive" prints made by hands dipped in paint and pressed on the wall, but they are most numerous at Gargas, where more than 150 have been found. At Gargas, red and black pigments were used, the red being earlier, and the prints are often arranged in horizontal rows, revealing, even at this early stage, a feeling for artistic composition and rhythmic repetition of motif. A curious feature of these handprints is that many are representations of mutilated hands with one or more finger joints missing, most frequently the last two joints of the last four fingers. Often the same mutilated hand is stenciled repeatedly over an area. This mutilation may have been the result of voluntary sacrificial amputation or, more likely, of disease associated with malnutrition and exposure to cold.

The significance of these handprints is unknown. The motif is widespread in Stone Age art, appearing not only in Ice Age Europe but also in the art of primitive hunter cultures in Africa, Australia, and America. It may have served primitive man as a sort of personal signature, defining his relationship with his tribe or with supernatural powers or perhaps sealing some promise made to his companions or to the gods. The imprinted hand may also have been a symbol of possession.

**gargoyle**, in architecture, waterspout designed to drain water from the parapet gutter. Originally the term referred only to the carved lions of classical cornices or to terra-cotta spouts, such as those found in the Roman structures at Pompeii. The word later became restricted mainly to the grotesque, carved spouts of the European Middle Ages. It is often, although incorrectly, applied to other grotesque beasts, such as the *chimères* (chimeras) that decorate the parapets of Notre-Dame at Paris. The

Gargoyle on the Parthenon, the Acropolis, Athens, 5th century bc

Alison Frantz

gargoyle of the developed Gothic period is usually a grotesque bird or beast sitting on its haunches on the back of a cornice molding and projected forward for several feet in order to throw the water far from the building.

**gargolism** (hereditary disorder): see Hurler's syndrome.

**Garian** (Libya): see Gharyān.

**Garibaldi, Giuseppe** (b. July 4, 1807, Nice, French Empire [now in France]—d. June 2, 1882, Caprera, Italy), Italian patriot and soldier of the Risorgimento, a republican who, by his conquest of Sicily and Naples with his guerrilla "Redshirts," contributed to the achievement of Italian unification under the royal House of Savoy.

*Early life.* Garibaldi's family was one of fishermen and coastal traders, and for more than 10 years he himself was a sailor. In 1832 he acquired a master's certificate as a merchant captain. By 1833–34, when he served in the navy of the Kingdom of Piedmont–Sardinia, he had come under the influence of Giuseppe Mazzini, the great prophet of Italian nationalism, and the French Socialist thinker, the Comte de Saint-Simon. Garibaldi, in 1834, took part in a mutiny intended to provoke a republican revolution in Piedmont, but the plot failed; he himself escaped to France and in his absence was condemned to death by a Genoese court.

Deutsche Fotothek, Dresden

*Exile in South America.* From 1836 to 1848 Garibaldi lived in South America as an exile, and these years of turmoil and revolution in that continent strongly influenced his career. He volunteered to serve the Rio Grande do Sul republic as a naval captain in the unsuccessful attempt by that small state to break free from the Brazilian Empire. Actually, he did little more than prey on Brazilian shipping. In the course of often harrowing adventures on land and sea, he managed to elope with Anna Maria Ribeiro da Silva (Anita), a married woman, who remained his companion in arms until her death. After a succession of victories by the Brazilians in 1839–40, he finally decided to leave the service of Rio Grande. Driving a herd of cattle, he made the long trek to Montevideo with Anita and their son. There he tried his hand as commercial traveller and teacher but could not accustom himself to civilian life. In 1842 he was put in charge of the Uruguayan Navy in another liberation war—this time against Juan Manuel de Rosas, the dictator of Argentina. The following year, again in the service of Uruguay, he took command of a newly formed Italian Legion at Montevideo; these men formed the first of the “Redshirts,” with whom his name became associated. After he won a small but heroic engagement at the Battle of Sant’Antonio in 1846, his fame reached even to Europe, and in Italy a sword of honour, paid for by subscriptions, was donated to him. For a short time in 1847 he was in charge of the defense of Montevideo. On this occasion he first came to the attention of Alexandre Dumas *père*, who later did much to foster his reputation. He also greatly impressed other foreign observers as an honest and able man. His South American experiences gave him invaluable training in the techniques of guerrilla warfare that he was later to use with great effect against French

and Austrian armies, which had not been taught how to counter them. These first exploits in the cause of freedom cast him in the mold of a professional rebel, an indomitable individualist who all his life continued to wear the gaucho costume of the pampas and to act as if life were a perpetual battle for liberty.

*War of liberation.* In April 1848 Garibaldi led 60 members of his Italian Legion back to Italy to fight for the Risorgimento, or resurrection, of Italy in the war of independence against the Austrians. He first offered to fight for Pope Pius IX, and—when his offer was refused—for Charles Albert, the king of Piedmont–Sardinia. The King, too, rebuffed him, for Garibaldi’s conviction as a rebel in 1834 was still remembered; moreover, the regular army despised this self-taught guerrilla leader. Garibaldi went, therefore, to the aid of the city of Milan, where Mazzini had already arrived and had given the war of liberation a more republican and radical turn. Charles Albert, after his defeat at the hands of the Austrians at Custoza, agreed to an armistice, but Garibaldi continued in the name of Milan what had become his private war, and emerged creditably from two engagements with the Austrians at Luino and Morazzone. But at the end of August, heavily outnumbered, he had to retreat across the frontier to Switzerland.

For a time Garibaldi settled down at Nice with Anita (whom he had married in 1842) and their three children, but his resolve to help free Italy from foreign rule was now stronger than ever. He was confirmed in his purpose by his belief—which he and only a handful of others shared with Mazzini—that the many Italian states, though often engaged in internecine warfare, could nonetheless be unified into a single state. When Pius IX, threatened by liberal forces within the Papal States, fled from Rome toward the end of 1848, Garibaldi led a group of volunteers to that city. There, in February 1849, he was elected a deputy in the Roman Assembly, and it was he who proposed that Rome should become an independent republic. In April a French army arrived to restore papal government, and Garibaldi was the chief inspiration of a spirited defense that repulsed a French attack on the Janiculum Hill. In May he defeated a Neapolitan army outside Rome at Velletri, and in June he was the leading figure in the defense of Rome against a French siege. There was no chance at all of holding the city, but the gallantry of the resistance became one of the most inspiring stories of the Risorgimento. Refusing to accept defeat, in July 1849 Garibaldi led a few thousand men out of Rome and through central Italy, manoeuvring to avoid French and Austrian armies, until he reached neutral territory in the republic of San Marino.

*Retreat.* There he found himself surrounded and decided to disband his men. Soon afterward, he himself was pursued by the Austrians as he tried to escape. Although Anita died during this escape, Garibaldi successfully crossed the Apennines to the Tuscan coast. The retreat through central Italy, coming after the defense of Rome, made Garibaldi a well-known figure wherever newspapers were read. From then on he was the “hero of two worlds.” Some people criticized his military skill in this campaign, but his qualities as a leader had proved to be extraordinary, and his courage and determination not to surrender were a lesson in patriotism to his fellow countrymen.

The Piedmontese monarchy, however, was too frightened to let this rebel return to his mother and his children, and soon he was in exile a second time, first at Tangier, then on Staten Island, then in Peru, where he returned to his original trade as a ship’s captain. Only in 1854 was he allowed to return to Italy; Conte di Cavour, the prime minister of Piedmont, believed that by this act he could pry

Garibaldi away from the republican Mazzini. In the following year Garibaldi bought part of the island of Caprera off the Sardinian coast, which remained his home for the rest of his life. In 1856 he tried to lead an expedition to release political prisoners held by the Bourbon kings of Naples, but it came to nothing. In 1858 he received an invitation from the Conte di Cavour to help prepare for another war against Austria. His task was to lead an army of volunteers collected from other provinces of Italy, and for this purpose he was given the rank of major general in the Piedmontese Army. When war broke out in April 1859, he led his Cacciatori delle Alpi (Alpine Huntsmen) in the capture of Varese and Como and reached the frontier of the south Tirol. This war ended with the acquisition of Lombardy by Piedmont.

In September 1859, after peace had returned to northern Italy, Garibaldi transferred his attention to central Italy, where a revolutionary government had established itself at Florence. There, on several occasions, he had private meetings with King Victor Emmanuel II of Piedmont–Sardinia, when it was agreed that he should prepare to invade the Papal States; the King would support his venture if it succeeded or disown him if it failed. At the last moment, however, the King realized that this was too dangerous and asked him to give up the idea. Garibaldi agreed, though reluctantly. He was ready at any moment to revive this kind of unwritten agreement with Victor Emmanuel, but it became increasingly clear that their aims were not entirely identical. Though both men were patriots, Garibaldi was already working for the unification of Italy; the King was more prudent and was concerned rather with expanding Piedmont as far as seemed feasible. Garibaldi was especially furious when, early in 1860, Cavour and Victor Emmanuel gave his hometown of Nice back to France (it had become Piedmontese in 1814), and he made one of his rare appearances in Parliament to protest this violation of the national principle. In January 1860 he married Giuseppina, the daughter of the Marchese Raimondi, but abandoned her, within hours of the marriage, when he discovered she almost certainly was five months pregnant by one of his own officers. Twenty years later, he was able to obtain the decree of nullity that enabled him to legitimize his children by Francesca Armosino.

*Conquest of Sicily and Naples.* In May 1860 Garibaldi set out on the greatest venture of his life, which was to result in the conquest of Sicily and Naples. This time he had no government backing, but Cavour and Victor Emmanuel did not dare to stop him, for he had become a popular hero. They stood ready to assist, but only if he proved successful, and he accepted this unwritten arrangement, confident that he could thus force Cavour to support a new move toward the unification of the Italian peninsula. Sailing from near Genoa on May 6 with about 1,000 men, he reached Marsala in Sicily on the 11th and in the name of Victor Emmanuel proclaimed himself dictator. A popular revolution in Sicily gave him considerable help, for his personal charm was irresistible, and many of the peasants thought him a god come to deliver them from slavery and feudalism. The decisive moment for his forces was a small engagement at Calatafimi, when he gave convincing proof that he could defeat the regular soldiers of the king of Naples’ army. Immediately there was a great popular movement in his support; and this helped him, at the end of May, to capture Palermo.

The seizure of Palermo was one of Garibaldi’s most remarkable military successes, and it convinced Cavour that this volunteer army should now be strongly, if still secretly, supported by Piedmont. Moving across the island, Garibaldi won the Battle of Milazzo in July, helped by reinforcements from northern

Italy. On August 18–19 he crossed over the Strait of Messina and landed on the mainland in Calabria. As always, his strategy was to deny the enemy a moment's pause. After a lightning campaign, he moved up through Calabria and on Sept. 7, 1860, entered Naples, Italy's largest city, where he proclaimed himself "Dictator of the Two Sicilies" (the name of the territories of the king of Naples, comprising most of southern Italy and Sicily). He then fought another battle on the Volturno River north of Naples. This was the biggest battle of his career, Garibaldi commanding about 30,000 men. After his victory he held plebiscites in Sicily and Naples, which allowed him to hand over the whole of southern Italy to King Victor Emmanuel. When the two met, he was the first person to hail Victor Emmanuel as king of a united Italy. The King made a triumphal entry into Naples on November 7, and Garibaldi sat beside him in the royal carriage. But immediately afterward the former dictator returned to Caprera, refusing all the rewards thrust on him. He had asked for only one thing—to be allowed to continue governing Naples as the King's viceroy until conditions returned to normal; but this was refused him, for in the eyes of the conservatives he was still a dangerous radical—an anticlerical who moreover professed to hold advanced ideas on social reform. He was also a man who was known to want to reconquer Rome from the pope and make it into Italy's capital. This was too dangerous a scheme for Victor Emmanuel, for there was a French garrison defending the papal temporal power in Rome. There was also another, more insidious danger: Garibaldi was more popular than the King himself. Furthermore, the regular army of Piedmont was deeply jealous of his successes and determined that he should not be permitted to score fresh ones. Finally, it was feared that Mazzini and the republicans might recapture Garibaldi's allegiance and make him desert the monarchical cause.

**Kingdom of Italy.** In 1861 a new kingdom of Italy came into existence, but from the start it found Garibaldi virtually in opposition. Many people regarded him as an embarrassment. He opposed Cavour in Parliament and he accused the government of shabby treatment of the volunteer soldiers who had conquered half the country and given it to the King. Also, he condemned the inefficient administration of the provinces that he had conquered and for which he felt especially responsible. In many ways he showed that he considered himself almost an independent power in his own right, both in his dealings with his own government and with foreign powers. So much admired was he outside the country that Pres. Abraham Lincoln in July 1861 offered him a command in the American Civil War; the offer was declined, partly because Lincoln would not make a sweeping enough condemnation of slavery, but also because he would not give Garibaldi supreme command of the Federal troops. Another sign of Garibaldi's reputation was the rapturous reception that he later received in England in April 1864. Perhaps never before in history had there been such a large spontaneous gathering as the one that cheered him through the streets of London.

**Last campaigns.** Early in 1862 Victor Emmanuel again persuaded Garibaldi to lead a revolutionary expedition, this time to attack Austria in the Balkans. He was allowed to recruit another volunteer army, and munitions were collected for him in Sicily; but he then decided to use this army to attack the Papal States. The Italian government did not want to jeopardize its relations with the French, who garrisoned the Papal States, and at this point ordered its own forces to stop Garibaldi. At the ensuing Battle of Aspromonte he was badly wounded and taken prisoner. He was freed, however, and now the King's complicity

with him could no longer be denied. His wound left him lame, but this did not prevent the government from using him more openly when war broke out with Austria in 1866. He was given an almost independent command in the Tirol, and once again he emerged from the war with a good deal more credit than any of the regular soldiers. This war led to the acquisition of Venice. In 1867 Garibaldi led another private expedition of his own into the Papal States. This, too, was secretly subsidized by the government, though, of course, the King pretended otherwise; but political mismanagement of the whole incident forced the French to intervene, and French troops defeated Garibaldi's volunteers at Mentana. Once more he was arrested by the Italian government in order to cover up its complicity, but he was soon released and taken back to Caprera. Garibaldi led one final campaign in 1870–71, when he went to assist the French Republic against Prussia. Again he distinguished himself, though on a small scale, and he was subsequently elected a member of the French National Assembly at Bordeaux.

During the last decade of his life he was crippled by rheumatism and by his many wounds. Though he had become something of a recluse on his island, he kept abreast of affairs through the numerous deputations that called on him, and he habitually made pronouncements on affairs of the day. Toward the end he called himself a Socialist, but both Karl Marx and the anarchist Mikhail Bakunin disowned him. He also became something of a pacifist, for his own experience had taught him that wars were seldom either righteous or effective in achieving their ends. He was a recognized champion of the rights of labour and of women's emancipation. He also showed himself a religious freethinker and ahead of his time in believing in racial equality and the abolition of capital punishment.

**Assessment.** Garibaldi was responsible for most of the military victories of the Risorgimento, not least because he was one of the great masters of guerrilla warfare. Almost equally important was his contribution as a propagandist to the unification of Italy. Himself a man of the common people, he knew far better than Cavour or Mazzini how to reach the masses with the new message of patriotism. Furthermore, the fact that he used his military and political gifts for liberal or nationalist causes coincided well with current fashion and brought him great acclaim. In addition, he attracted support by being a truly honest man who asked little for himself.

But his forthright innocence coloured his politics. Not interested in power for himself, he believed in dictatorship because of his South American experiences. He distrusted parliaments because he saw them to be ineffective and corrupt. Actually, his own dictatorship of southern Italy in 1860, though much criticized, compares surprisingly well with the subsequent administration by the Kingdom of Italy. There was little of the intellectual about Garibaldi, yet his simpleminded radicalism for the first time created some kind of political awareness in many of his fellow countrymen and brought home to them what nationality signified. Notwithstanding his turn toward Socialism, he remained primarily a nationalist—but the object of his nationalism was always the liberation of peoples and not patriotic aggrandizement. To his embodiment of this aim he owes his eminent place in Italian history. (De.M.S.)

**BIBLIOGRAPHY.** Garibaldi's memoirs are most easily available in the 2-volume edition by A. Werner, *Autobiography of Giuseppe Garibaldi* (1889), with an interesting supplementary volume about him by his friend Jessie White Mario. Another version of the memoirs was partially ghosted by Alexandre Dumas, trans. by R.S. Garnett, *The Memoirs of Garibaldi* (1931). Some other of Garibaldi's writings, and many comments on him by

contemporaries, may be found in *Garibaldi*, ed. by D. Mack Smith (1969). Three excellent studies are G.M. Trevelyan, *Garibaldi's Defense of the Roman Republic* (1907, reprinted 1971), *Garibaldi and the Thousand* (1909, reprinted 1979), and *Garibaldi and the Making of Italy* (1911). The shortest modern biography is D. Mack Smith, *Garibaldi: A Great Life in Brief* (1956); more substantial are Jasper Ridley, *Garibaldi* (1974), and John Parris, *The Lion of Caprera* (1962). On his private life, by friends of his, there should be noted Marie Esperance von Schwartz, *Garibaldi: Recollections of His Public and Private Life* (1887); and Augusto Vecchi, *Garibaldi at Caprera*.

**Garibaldi, Mount,** peak in southern British Columbia, Canada, in the Coast Mountains east of the Cheakamus River. Glacier-capped, it is 8,787 ft (2,678 m) high and is the focus of Garibaldi Provincial Park (area 760 sq mi [1,968 sq km]), established in 1927 and now a popular year-round recreational district. The park includes a nature conservancy (area 69 sq mi) and is 40 mi (64 km) north of Vancouver. Capt. George H. Richards of the survey ship "Plumper" named the peak c. 1860 for the Italian patriot.

**Garis, Howard R(oger)** (b. April 25, 1873, Binghamton, N.Y., U.S.—d. Nov. 6, 1962, Amherst, Mass.), author, creator of the Uncle Wiggily series of children's stories, who began his career as a newspaperman on the *Newark Evening News* in 1896. Shortly after, he began writing a daily bedtime story about Uncle Wiggily—a rabbit hero—and his friends. He averaged a story a day (except Sunday) until he retired in 1947. In all, he turned out more than 15,000 stories and about 500 books.

**Garissa,** town, headquarters of Garissa district, and capital of North-Eastern Province, east central Kenya, East Africa. The town is a market centre situated on the Tana River, and its industries process food and tobacco products; manufactures include plastic containers and beverages. It is located about 215 mi (350 km) east of Nairobi and is linked by road with Nairobi, Mombasa, and Alanga Arba. Pop. (1989) 31,319.

**Garland,** city, Dallas county, northern Texas, U.S. Adjacent to Dallas (west), it was founded when two rival railroad communities, Duck Creek and Embrce, were consolidated in 1887 by an act of the U.S. Congress and named for Attorney General Augustus H. Garland. Its economy is industrialized and supplemented by the farm crops grown on the nearby Blacklands Belt. A wide variety of manufactures includes electronic equipment, chemicals, and scientific instruments. A branch of Abilene Christian University is there. Pop. (2000) 215,768.

**garland,** a band, or chain, of flowers, foliage, and leaves; it may be joined at the ends to form a circle (wreath), worn on the head (chaplet), or draped in loops (festoon or swag). Garlands have been a part of religious ritual and tradition from ancient times: the Egyptians placed garlands of flowers on their mummies as a sign of celebration in entering the afterlife; the Greeks decorated their homes, civic buildings, and temples with garlands and placed them crosswise on banquet tables; in ancient Rome, garlands of rose petals were worn, and carved wooden festoons (a craft revived in the 17th and 18th centuries) decorated homes. These garlands are a recurrent motif in classical and Renaissance paintings and relief sculptures. In the Byzantine culture a spiral garland made with foliage and tiny flowers was popular as were those of narrow bands of alternating fruit or flowers and foliage. During the 15th and 16th centuries garlands of fruits and flowers, especially of roses, were worn in pageants, festivals, and at weddings, a custom echoed in

the folk festivals of Europe in which cattle are decked with flowers and dances are performed with chains of flowers linking the participants (garland dance). The religious significance of

Garland of leaves and fruit arranged over a throne, "Madonna della candelletta" by Carlo Crivelli, in the Brera, Milan

SCALA—Art Resource/EB Inc

garlands was evident in the European Middle Ages (c. 5th–15th centuries) when they were hung on religious statues. The Hindus in India also attach a spiritual meaning to flowers, wearing and adorning their statues with blessed garlands. *See also* wreath.

**Garland, (Hannibal) Hamlin** (b. Sept. 14, 1860, West Salem, Wis., U.S.—d. March 4, 1940, Hollywood, Calif.), American author perhaps best remembered for his short stories and his autobiographical "Middle Border" series of narratives.

As his farming family moved progressively westward from Wisconsin to Iowa and then to the Dakotas, Garland rebelled against the vicissitudes of pioneering and went to Boston for a career in 1884. Self-educated there, he gradually won a place for himself in the literary set of Boston and Cambridge and was influenced by the novelist William Dean Howells. Garland recorded the physical op-

pression and economic frustrations of pioneer life on the Great Plains in the short stories that were collected in *Main-Travelled Roads* (1891), one of his best works. The short stories he published in *Prairie Folk* (1892) and *Way-side Courtships* (1897) were later combined in *Other Main-Travelled Roads* (1910). In 1892 Garland published three lacklustre novels. His next novel, *Rose of Ducher's Coolly* (1895), tells the story of a sensitive young woman who rebels against the drudgery of farm life and goes to Chicago to pursue her talent for literature. Garland's critical theory of "veritism," set forth in the essay collection *Crumbling Idols* (1894), called for the use of socially conscious realism combined with more individualistic and subjective elements.

Garland next turned to the "high country" of the American West and to romantic melodrama for materials, producing a series of mediocre novels that were serialized in the popular "slick magazines." He grew increasingly critical of the "excesses" of the naturalists, and in 1917 in a mellow autobiographical mood wrote *A Son of the Middle Border*, in which he described his family background and childhood as the son of pioneer farmers. This book won immediate and deserved acclaim. Its sequel, *A Daughter of the Middle Border* (1921), was less successful, as were *Trail-Makers of the Middle Border* (1926) and his last historical and autobiographical novels.

**Garland, John**, also called JOHANNES DE GARLANDIA (b. c. 1180, England—d. c. 1252), English grammarian and poet whose writings were important in the development of medieval Latin. Though much of his life was spent in France, his works were influential mainly in England.

Garland went to Paris (1202) to complete his studies and remained there as a teacher until 1229, when he went to the University of Toulouse. He fled Toulouse, however, in 1232 or 1233 because of conflicts ensuing from the defeat of the heretical Cathari, or Albigenses.

Among his grammatical works were *Compendium grammaticae* ("Outline of Grammar"), *Liber de constructionibus* ("Book on Constructions"), and a Latin vocabulary. Two of his best-known poems are *De triumphis ecclesiae* ("On the Triumphs of the Church"), which gives a detailed account of the crusade against the Cathari, and *Epithalamium beatae Mariae Virginis* ("Bridal Song of the Blessed Virgin Mary"). *Scolarium morale* covers topics such as general behaviour, table manners, virtue, and the defense of the pope against charges of simony.

**Garland, Judy**, original name FRANCES GUMM (b. June 10, 1922, Grand Rapids, Minn., U.S.—d. June 22, 1969, London, Eng.), American motion-picture singer and actress.

The daughter of vaudeville performers, Garland made her stage debut at the age of three. She toured the United States with her sisters (The Gumm Sisters) in a musical act until her screen debut in the short film *Every Sunday* (1936). Achieving critical notice for the musical *Broadway Melody of 1938* (1937), she followed with *Thoroughbreds Don't Cry* (1937), a film that initiated her partnership with the juvenile star Mickey Rooney. They appeared together in such films as *Love Finds Andy Hardy* (1938), *Babes in Arms* (1939), *Babes on Broadway* (1941), and *Girl Crazy* (1943). *The Wizard of Oz* (1939), based on the novel by L. Frank Baum, brought Garland international stardom and became a film classic, for which she was honoured with a special Academy Award. Musical hits, such as *For Me and My Gal* (1942), *Meet Me in St. Louis* (1944), *The Harvey Girls* (1946), *Easter Parade* (1948), and *Summer Stock* (1950) followed.

The last 15 years of Garland's life were troubled by a growing reliance on drugs, repeated

Judy Garland

Brown Brothers

suicide attempts, and nervous breakdowns. She made spectacular comebacks, however, and her personal singing appearances in London and New York broke box-office records. Many of her fans saw suggestions of her personal misfortunes in her masterly performance in the film *A Star Is Born* (1954), and her dramatic portrayal in *A Child Is Waiting* (1963) was also acclaimed. She died from an overdose of sleeping pills.

Liza Minnelli (b. 1946), the daughter of Garland and the motion-picture director Vincente Minnelli (married 1945, divorced 1951), also became a singer and actress.

**garland flower** (plant): *see* ginger lily.

**garlic** (species *Allium sativum*), bulbous perennial plant of the lily family (Liliaceae). The plant's bulbs are used as a flavouring. A classic ingredient in many national cuisines, garlic has a powerful, onionlike aroma and pungent taste; its wide use in the United States originated among European immigrant groups. In ancient and medieval times garlic was prized for its medicinal properties and was carried as a charm against vampires and other evils. Garlic bulbs are used either sliced or ground to flavour tomato sauces, stews, and salad dressings in southern European and Asian cuisines.

Garlic (*Allium sativum*)

A-Z Botanical Collection—EB Inc

Garlic is native to central Asia but also grows wild in Italy and southern France. The membranous skin of the garlic bulb encloses up to 20 edible bulblets called cloves. Flower stalks sometimes arise bearing tiny bulblets and blossoms without seeds. Garlic is propagated by planting cloves or top bulblets. Garlic is grown as an annual crop by methods similar to those used in growing onions. Garlic contains about 0.1 percent essential oil, the principal components of which are diallyl disulfide, diallyl trisulfide, and allyl propyl disulfide.

**garment industry**, the manufacture of clothing. *See* dress; textile.

**Garmisch-Partenkirchen**, market town, Bavaria *Land* (state), southern Germany. It lies at the junction of the deep Loisach and Partnach valleys, in the Bavarian Alps at the foot of the Zugspitze (9,718 feet [2,962 m]), which is the highest mountain in Germany. The town, a union of the two ancient villages of Garmisch and Partenkirchen, was chartered in 1935 and retains much of its rural character.

Notable buildings are the medieval Old Church of St. Martin (Alte Kirche), the Baroque parish New Church of St. Martin in Garmisch, and the 18th-century Pilgrimage Church of St. Anton in Partenkirchen. Scene of the 1936 Winter Olympics, the town is a health and winter sports resort, with ski facilities, an Olympic skating rink, rack and cable railways, and summer mountain-climbing facilities. Pop. (1995 est.) 26,992.

**Garneau, François-Xavier** (b. June 15, 1809, Quebec, Lower Canada [now Quebec, Can.]—d. Feb. 3, 1866, Quebec), first outstanding French-Canadian historian, known as the father of Canadian historiography.

The son of a carriage maker, Garneau left school at the age of 14 and entered the court clerk's office and two years later a notary's firm, becoming a notary himself in 1830. He was in London from 1831 to 1833 as secretary to D.B. Viger, a Canadian political delegate.

Garneau, detail from a lithograph

By courtesy of the Public Archives of Canada

Back in Quebec he wrote poetry, started two short-lived periodicals, dabbled in history, and in 1837 became a bank cashier. Active in local politics, Garneau was appointed translator to the legislative assembly (1843) and was the city clerk of Quebec (1844–64).

Garneau's *Histoire du Canada* (1845–48), predominantly a political and military account of early Quebec, includes tales of pioneering men and women and descriptions of the major civil, political, and religious leaders. An attempt to conserve Quebec's religion, language, and laws, the work met with great success and inspired a reawakening of interest by poets, novelists, and other historians in French-Canadian culture.

**Garneau, Hector de Saint-Denis** (b. June 13, 1912, Sainte-Catherine-de-Fossambault, Que., Can.—d. Oct. 24, 1943, Sainte-Catherine-de-Fossambault), poet who was the cofounder of the important French-Canadian literary journal *La Relève* (1934; "The Relief"). His intense and introspective verse, filled with images of death and suicide, set him apart from the prevailing regionalism of Canadian literature and strongly influenced the poets who followed.

Garneau was the great-grandson of the historian François-Xavier Garneau. In his early 20s, he suffered a heart attack and lived thereafter in increasing solitude, writing poetry that reflects the despair he felt over his joyless life. He published only one volume of poetry, *Regards et jeux dans l'espace* (1937; "Glances and Games in Space"), in his lifetime. His *Poésies complètes* (1949; "Complete Poetry")

and *Journal* (1954), an intimate record of his life between 1935 and 1939, appeared posthumously.

**Garner, John Nance**, byname CACTUS JACK GARNER (b. Nov. 22, 1868, Red River county, Texas, U.S.—d. Nov. 7, 1967, Uvalde, Texas), U.S. Democratic vice president (1933–41) who maintained his conservatism despite his position within the New Deal administration of President Franklin D. Roosevelt.

Admitted to the Texas bar in 1890, Garner served two terms in the state legislature (1898–1902) before being elected to the U.S. House

Garner

Encyclopaedia Britannica, Inc.

of Representatives, where he remained for 30 years (1903–33). As a congressman, Garner was especially expert at backstage maneuvering to expedite legislation. He supported the graduated income tax and the federal reserve system and came to be regarded by 1917 as one of the most influential politicians in Congress. After serving successively as Democratic whip and floor leader, he was elected speaker of the House (1931).

At the 1932 Democratic National Convention, Garner was himself a candidate for the presidency, but he released his delegates from Texas and California to ensure the nomination of Roosevelt. The choice of Garner for the vice presidency assuaged party conservatives. He in fact never felt comfortable in the New Deal, which he deemed "too liberal." Although reelected in 1936, he broke with the administration in 1937 over efforts to "pack" (enlarge) the Supreme Court. At the end of his second term he retired to his Texas ranch.

**Garnerin, André-Jacques** (b. Jan. 31, 1769, Paris, France—d. Aug. 18, 1823, Paris), French aeronaut, the first person to use a parachute regularly and successfully. He perfected the parachute and made jumps from greater altitudes than had been possible before.

As a young man Garnerin studied physics. In 1793 he became an inspector in the French army, where he encouraged the use of balloons for military purposes, but he was captured during hostilities with England and was imprisoned for two years. On his return to France he began to make balloon ascents, giving his first exhibition of parachuting in Paris in 1797, when he jumped from a height of about 3,200 feet (1,000 m). Garnerin continued his exhibitions in cities throughout northern Europe, making a spectacular jump from 8,000 feet (2,440 m) in 1802, in England. His white canvas parachute was umbrella-shaped and approximately 23 feet (7 m) in diameter. In most of his aeronautical enterprises, he worked with his brother Jean-Baptiste-Olivier Garnerin (1766–1849).

**garnet**, any member of a group of common silicate minerals that have similar crystal structures and chemical compositions. Garnets are most commonly found in metamorphic rocks, but also in certain types of igneous rocks, and, usually in minor amounts, in clastic sediments and sedimentary rocks. They may be

colourless, black, and many shades of red and green. The garnet is the birthstone associated with the month of January.

A brief treatment of garnets follows. For full treatment, see MACROPAEDIA: Minerals and Rocks.

Use of garnets as gems began with the ancient Egyptians, if not earlier. During the latter part of the 19th century, garnet bracelets and brooches were particularly popular. Most familiar during the peak of popularity were varieties of pyrope, cut either with a convex polished surface (en cabochon) or with facets. Garnet varieties have become known by misleading names, frequently consisting of a locality with the name of another mineral variety, such as Uralian emerald or Cape ruby.

The hardness of garnets and their sharp fracture make them suitable as abrasives. Higher-grade garnets are used in fine sanding and polishing of wood, leather, glass, metals, and plastics. Lower-grade garnets are used as sand-blasting agents and in nonskid surface coatings.

At Gore Mountain, N.Y., U.S., garnet crystals average 13 cm (5 inches) in size but reach a maximum of a metre or so. Consisting principally of almandine and pyrope, they are the hardest of the abrasive garnets (approximately 8 on the Mohs scale). Garnets have also been mined in Maine and Idaho. Outside the United States (the world's leading producer), notable quantities have been produced in Australia, China, and India.

The general formula for the chemical composition of garnets is  $A_3B_2(SiO_4)_3$ , in which the  $A$  may be divalent ions of calcium, magnesium, iron, or manganese, and  $B$  may be trivalent ions of aluminum, iron, chromium, or more rarely manganese, titanium, vanadium, or zirconium. Garnets may contain other metallic atoms in minor amounts as well as nonmetallic constituents other than silicon. Most natural garnets are mixtures of two or more of the following pure species:

pyrope	$Mg_3Al_2(SiO_4)_3$
almandine	$Fe_3Al_2(SiO_4)_3$
spessartine	$Mn_3Al_2(SiO_4)_3$
uvarovite	$Ca_3Cr_2(SiO_4)_3$
grossular	$Ca_3Al_2(SiO_4)_3$
andradite	$Ca_3Fe_2(SiO_4)_3$

The first three (pyrope, from *pyrope*, almandine, and spessartine) form solid solutions with one another, as do the last three (ugrandite, from *uvarovite*, *grossular*, and *andradite*). Pyrope and ugrandite do not mix. For detailed physical properties, see silicate mineral (table). For gem varieties, see also pyrope; almandine; spessartine; uvarovite; grossular; andradite; and hessonite.

INDEX  
first

**Garnet, Henry Highland** (b. 1815, New Market, Md., U.S.—d. Feb. 13, 1882, Liberia), leading black Abolitionist and clergyman.

Born a slave, Garnet escaped in 1824 and made his way to New York. There he pursued an education and eventually became a Presbyterian minister. Garnet became associated with the American Anti-Slavery Society, and his career in the late 1830s and early '40s joined preaching with agitation for emancipation. A nationally known figure, he shocked his listeners at the 1843 national convention of free people of colour when he called upon slaves to murder their masters. The convention refused to endorse Garnet's radicalism, and he gradually turned more to religion as Frederick Douglass assumed the role of premier black Abolitionist.

During the next two decades, Garnet served as pastor in a number of Presbyterian pulpits. While at his post in Washington, D.C., in 1864, he aided the war-related displaced and distressed. Later, he assisted government workers in developing programs to help former slaves.

In 1881 Garnet was appointed minister to Liberia. In his younger, more radical days, he had vigorously opposed plans to solve America's slavery problem by sending blacks back to Africa. Toward the end of his life, however, he favoured U.S. blacks' emigration back to Africa. Within two months of his arrival in the African nation, though, he died.

**Garnett, Constance (Clara)**, *née* BLACK (b. Dec. 19, 1861, Brighton, East Sussex, Eng.—d. Dec. 17, 1946, Edenbridge, Kent), English translator who made the great works of Russian literature available to English and American readers in the first half of the 20th century. The first to render Dostoyevsky and Chekhov into English, she also translated the complete works of Turgenev and Gogol and major works of Tolstoy.

In 1879, when advanced education for women was unusual, she won a scholarship to Newnham College, Cambridge. After her marriage to the critic Edward Garnett and the birth of their son David, the future novelist, in 1892, she began her career as a translator with Ivan Goncharov's *Obyknovennaya istoriya* (1847), which she rendered as *Common Story* (1894). Altogether she produced about 70 volumes of translations from Russian literature.

**Garnett, David** (b. March 9, 1892, Brighton, East Sussex, Eng.—d. Feb. 17, 1981, Le Verger Charry, Montcuq, Fr.), English novelist, son of Edward and Constance Garnett, who was the most popularly acclaimed writer of this literary family.

A prolific writer, he is best known for his satirical fantasies *Lady into Fox* (1922), the tale of a man whose wife is suddenly transformed into a fox, and *A Man in the Zoo* (1924), concerned with a man who is accepted by the London Zoo to be exhibited as an example of *Homo sapiens*. Later novels, not fantastic, were not so successful. In *The Golden Echo* (1953), *The Flowers of the Forest* (1955), and *The Familiar Faces* (1962) Garnett described his memories of the English literary coterie—including the Bloomsbury group—of which he was a member during the period of World War I and the 1920s. *Great Friends: Portraits of Seventeen Writers* (1980) continued in the same vein. His other novels include *Aspects of Love* (1955), *Two by Two* (1963), and *A Clean Slate* (1971). He edited several collections of correspondence, including *The Letters of T.E. Lawrence* (1938) and *Carrington: Letters and Extracts from Her Diaries* (1978).

**Garnett, Edward (William)** (b. Feb. 19, 1868, London—d. Feb. 21, 1937, London), influential English critic and publisher's reader who discovered, advised, and tutored many of the great British writers of the early 20th century.

The son of the writer and librarian Richard Garnett, he was more influenced by his family's literary interests than by his slight formal education. Through extensive reading Garnett developed a nearly unerring ability to recognize genuine and original literary talent. Among the authors he discovered or befriended were Joseph Conrad, D.H. Lawrence, John Galsworthy, Ford Madox Ford, W.H. Hudson, and Stephen Crane. Garnett's own fiction, which he produced in quantity, was unsuccessful. He was the husband of the translator Constance Garnett and father of the novelist David Garnett.

**Garnett, Henry** (b. 1555, Heanor, Derbyshire, Eng.—d. May 3, 1606, London), English Jesuit superior implicated in the Gunpowder Plot, an abortive conspiracy to destroy the Protestant king James I of England and Parliament while in assembly on Nov. 5, 1605, in retaliation for stricter penal laws against Roman Catholics.

Garnett was raised in the Anglican faith but became converted to Roman Catholicism and in 1575 went to Rome, where he joined the Society of Jesus and became a professor of Hebrew at the Roman College. He returned to England as a missionary in 1586, becoming Jesuit superior in England the following year. The extent of his role in the Gunpowder Plot is disputed. He was not an active conspirator but associated with the plotters on a number of occasions. When arrested and tried in 1606, he at first denied all knowledge of the plot but

Garnett, engraving by Jan Wierix, early 17th century

By courtesy of the Trustees of the British Museum, photograph, J.R. Freeman & Co. Ltd.

later admitted having learned of it under the seal of confession. He protested his innocence but was executed.

**Garnett, Richard** (b. Feb. 27, 1835, Lichfield, Staffordshire, Eng.—d. April 13, 1906, London), English writer, librarian, and the head of the Garnett family, which exerted a formative influence on the development of modern British writing. From the age of 15 until his retirement in 1899 he was in the employ of the British Museum.

After initially working as a clerk, Garnett served as keeper of the printed books, the position his philologist father, Richard, had previously held. He later became chief keeper of the museum and received an honorary LL.D. degree from Edinburgh. Largely through his efforts, a general catalog of the British Museum was published in 1905, after 25 years of preparation. In 1862 Garnett published some previously undiscovered poetry of Shelley. Garnett's other published works were biographical and historical, in addition to poetry, translations, and essays. Best known among his fiction is *The Twilight of the Gods, and Other Tales* (1888), a collection of fables in the style of Lucian. In the British Museum, he became a legend to generations of readers and researchers for his extensive scholarship and prodigious memory.

**Garnier, Bernard** (counter-antipope): *see* Benedict (XIV).

**Garnier, (Jean-Louis-) Charles** (b. Nov. 6, 1825, Paris—d. Aug. 3, 1898, Paris), French architect of the Beaux-Arts style, famed as the creator of the Paris Opera House. He was admitted to the École des Beaux-Arts in 1842 and was awarded the Grand Prix de Rome in 1848 to study in Italy.

He won the 1860 competition for the new Paris Opera House. One of the most famous buildings of the century, the Opéra (completed 1875) became a symbol of Second Empire taste, and its eclectic neo-Baroque style became characteristic of late 19th-century Beaux-Arts design. Garnier's command of the sweeping

Opera House, Paris, by Charles Garnier, begun 1861  
Michel Serrailleur—Rapho/Photo Researchers

interiors was equalled by his mastery of balance, punctuation, and termination of mass and surface.

Garnier also influenced the style of resort architecture for the wealthy with his small theatre for the casino of Monte-Carlo (1878), the casino and baths at Vittel, and the villas he built in Bordighera, notably his own (1872-73). Among his other works were the observatory at Nice, an apartment house, and the Hôtel du Cercle de la Librairie in Paris.

For the Paris Exposition of 1889 he conceived the Exposition des Habitations Humaines, which became the subject of his book *L'Habitation humaine* (with A. Ammann, 1892). He also published, in 1871, *Le Théâtre* and, in 1876-81, *Le Nouvel Opéra de Paris*, a monumental description and defense of his work.

**Garnier, Francis**, French in full MARIE-JOSEPH-FRANÇOIS GARNIER (b. July 25, 1839, Saint-Étienne, Fr.—d. Dec. 21, 1873, outside Hanoi, Vietnam), French naval officer, colonial administrator, and explorer.

Garnier, the son of an army officer, overcame parental opposition to enter the naval school at Brest in 1856. Upon completion of his training he was posted as an ensign aboard a ship forming part of the French expeditionary force sent to China in 1860. He accompanied Adm. Léonard Charner to Saigon in 1861 and took part in the Battle of Chi Hoa that marked the end of effective Vietnamese resistance to the French advance into southern Vietnam (Cochinchina). In 1863 Garnier joined the newly formed colonial administration in Cochinchina, while still retaining his naval rank, and was appointed prefect of Cho Lon, the twin city to Saigon.

An enthusiastic believer in France's imperial destiny, Garnier vigorously advocated the expansion of French power in Vietnam and the commercial benefits he believed would flow from the exploration of the Mekong River. Largely as the result of his advocacy, a French expedition led by Doudart de Lagrée, with Garnier as second in command, left Saigon to explore the Mekong in June 1866. The mission was a failure in commercial terms, and the river was found to be unnavigable by boats of any size. But the explorers, despite great hardships and frequent sickness that finally took Lagrée's life, accomplished a major task in mapping unknown territory, and they were the first Europeans to enter Yunnan province by a southern route. Garnier, who assumed command of the expedition after Lagrée's death three months before its completion in June 1868, was honoured by the award of several medals.

Garnier was in France supervising the publication of an account of the Mekong River expedition when the Franco-German War broke out. He served with distinction during the siege of Paris but was passed over for promotion because of his public criticism of the peace terms imposed on France. Disappointed by this development and resentful of suggestions

that he had denigrated Doudart de Lagrèe's role in the exploration of the Mekong, Garnier travelled to China in the hope of combining exploration with commercial success.

He was called to Saigon from Shanghai in August 1873, when the French governor of Cochinchina, Adm. Marie-Jules Dupré (q.v.), sought to take advantage of an unauthorized attempt by a French trader, Jean Dupuis (q.v.), to open the Red River for commerce with China. Although Garnier's formal orders instructed him to extricate Dupuis from the Hanoi region of northern Vietnam, he appears to have received secret instructions from Dupré to establish a French position in the area. Such a plan was contrary to French government policy, but both Dupré and Garnier seem to have believed that a successful seizure of territory would result in approval from Paris.

Garnier reached Hanoi on Nov. 5, 1873, and forced a confrontation with Vietnamese officials. On November 20 he led an attack against the Hanoi citadel and was able, with his small band of well-equipped troops, to overcome a numerically superior Vietnamese force. This action was followed by Garnier's troops seizing other positions in the Red River Delta. By mid-December, however, the Vietnamese authorities had enlisted the aid of the Chinese Black Flag bandits led by Liu Yung-fu. In attempting to repel the Black Flag forces that attacked the Hanoi citadel on Dec. 21, 1873, Garnier was killed. His actions were disavowed by Governor Dupré, and, despite the opposition of Dupuis and others, a French envoy, Paul-Louis-Félix Philastre (q.v.), negotiated a withdrawal from northern Vietnam in early 1874.

Garnier, impetuous and headstrong, held a chauvinist vision of France's role in Asia that appealed to many of his contemporaries. He was at the same time a man of wide accomplishments in history, languages, and general science, in addition to his skills as a navigator and cartographer. The account he prepared of the Mekong River expedition, *Voyage d'exploration en Indo-Chine, 1866-68* (1873; "Voyage of Exploration in Indochina, 1866-68"), is a most valuable record of the political and economic situation of the countries through which the explorers passed in the 1860s.

**Garnier, Robert** (b. c. 1545, La Ferté Bernard, Fr.—d. Sept. 20, 1590, Le Mans), outstanding French tragic dramatist of his time.

While a law student at Toulouse, Garnier won two prizes in the *jeux floraux*, or floral games (an annual poetry contest held by the

Robert Garnier, detail of an engraving  
H. Roger-Viollet

Académie des Jeux Floraux). He published his first collection of lyrical pieces, now lost, *Plaintes Amoureuses de Robert Garnier*, in 1565. After practice at the Parisian bar he became *conseiller du roi* in his native district and later *lieutenant-général criminel*.

In his early plays Garnier was a follower of the Senecan school. His pieces in this style are *Porcie* (1568), *Hippolyte* (1573), and *Cor-*

*nèlie* (1574). His next group of tragedies—*Marc-Antoine* (1578), *La Troade* (1579), *Antigone* (1580)—shows an advance in technique beyond the plays of Étienne Jodelle, Jacques Grévin, and his own early plays, since the rhetoric is accompanied by some action.

In 1582 and 1583 he produced his two masterpieces, *Bradamante* and *Les Juives*. In *Bradamante*, the first important French tragicomedy, which alone of his plays has no chorus, he turned from Senecan models and sought his subject in Ariosto. The romantic story becomes an effective drama in Garnier's hands. Although the lovers, Bradamante and Roger, never meet on the stage, the conflict in the mind of Roger supplies a genuine dramatic interest. *Les Juives* is the story of the barbarous vengeance of Nebuchadnezzar on King Zedekiah and his children. This tragedy, almost entirely elegiac in conception, is given unity by the personality of the prophet.

Garnier was a Catholic and a patriot; he used his tragedies to convey moral and religious arguments to his contemporaries, who were then suffering in the Wars of Religion. His fine verse reflects the influence of his friend Pierre de Ronsard. His plays, which contain many affecting emotional scenes, were performed to the end of the 16th century.

**Garnier, Tony** (b. Aug. 13, 1869, Lyon—d. Jan. 19, 1948, Roquefort-la Bédoule, Fr.), a forerunner of 20th-century French architects, notable for his *Cité Industrielle*, a farsighted plan for an industrial city. He is also remembered, along with Auguste Perret, for the pio-

Tony Garnier, 1920  
AIGLES

neering use of reinforced concrete.

On his Prix de Rome grant Garnier developed plans (beginning in 1898, exhibited in 1904, and published in 1917) for an entire industrial city, embracing new concepts in city planning: long, narrow lots running east-west, buildings separated by wide open spaces, separate levels provided for pedestrians, and houses with roof gardens. The plan called for the extensive use of reinforced concrete.

In 1905 Garnier was appointed architect of Lyon, a position he held until 1919. The most important work in Lyon to emerge from his *Cité Industrielle* was the large stockyards complex of 1908-24. Other works include the stadium (1913-18), the Grange Blanche Hospital with its 22 pavilions (started in 1911, completed in 1927), the War Memorial (1924), and the housing project known as Les États Unis (1920-35; The United States).

Dora Wiebenson, *Tony Garnier: The Cité Industrielle* (1969), is well illustrated.

**Garnier-Pagès, Louis-Antoine** (b. Feb. 16, 1803, Marseille, Fr.—d. Oct. 31, 1878, Paris), republican political figure prominent in the opposition to France's monarchical regimes from 1830 to 1870.

Garnier-Pagès was an active participant in the antiroyalist uprising of 1830, but he did not formally enter politics until 1842, when

he was elected to the Chamber of Deputies from the Eure region. In 1842-48 he sat with the republican left and devoted himself to financial and commercial questions.

In 1848, as the Orleanist regime of King Louis-Philippe began to topple, Garnier-Pagès

Garnier-Pagès, lithograph  
H. Roger-Viollet

emerged as a leader of the "banquets campaign," a series of anti-regime political rallies. When Louis-Philippe abdicated, Garnier-Pagès became mayor of Paris and then minister of finance in a new republican government. Faced with a desperate financial situation, he enacted a series of stringent fiscal measures, including a surcharge on direct taxation, which caused great public dissatisfaction and brought about his defeat in a bid for election to the Legislative Assembly (1849). His *Histoire de la révolution de 1848*, 11 vol. ("History of the Revolution of 1848"), appeared in 1864.

During the Second Empire (1852-70) Garnier-Pagès remained in private life until 1864 and then became a member of the Corps Législatif. He opposed the Franco-German War (1870-71) but joined the republican Government of National Defense when Emperor Napoleon III abdicated in 1870. Once again, however, unpopularity cost him a seat in the legislature in 1871, and he retired from public life. He wrote an account of his experiences during the Second Empire, *L'Opposition et l'empire*, 2 vol. (1872; "The Opposition and the Empire").

**garnish**, an embellishment added to a food to enhance its appearance or taste. Simple garnishes such as chopped herbs, decoratively cut lemons, parsley and watercress sprigs, browned breadcrumbs, sieved hardcooked eggs, and broiled tomatoes are appropriate to a wide variety of foods; their purpose is to provide contrast in colour, texture, and taste, and to give a finished appearance to the dish.

In the classic cuisine of France, garnishes comprised any accompaniment to a principal dish—vegetables and starch dishes fell under this definition. Further, basic dishes could be varied by the selection of one of a codified array of garnishes. Under this system a chicken, for example, could be served *à la archiduc*, with a sauce of paprika and cream; *à la forestière*, with morels and potatoes; *à la bouquetière*, with an array of individually cooked, decoratively cut vegetables, and so on into hundreds of formulations.

**garnishment** (from Middle French *garnir*, meaning "to warn"), a process by which a creditor can obtain satisfaction of an indebtedness of the debtor by initiating a proceeding to attach property or other assets. A common form of garnishment involves a creditor attaching the wages of an employee owed to him by his employer. The creditor instituting the proceedings is the garnisher, the person indebted is the debtor-employee, and the party holding the property (the employer) is the garnishee. The result of a garnishment of salary

proceeding, if successful, is an order of the court requiring the employer to deduct and pay to the creditor a percentage of the debtor's salary until the debt is satisfied.

The remedies of garnishment and attachment are traceable to Roman law and were a recognized practice of medieval merchants. The availability and scope of the remedy today depends on statutory authorization; statutory provisions differ among the various countries having garnishment statutes.

**Garo Hills**, physical region, western Meghalaya state, northeastern India. It comprises the western margin of the Shillong Plateau (*q.v.*) and rises to an elevation of 4,600 feet (1,400 m). Drained by various tributaries of the Brahmaputra River, it has extremely high rainfall and is heavily forested.

The region has an agricultural economy, with rice, cotton, sal, bamboo, and lac as the principal products. Large quantities of coal and limestone and some petroleum have been found. Its clans practice a complex matrilineal social system. The population is mainly Gāro.

**Garofalo, Benvenuto do**, also called **BENVENUTO TISI**, or **TISIO** (b. 1481—d. 1559), Italian painter, who was the most prolific 16th-century painter of the Ferrarese school.

Garofalo's first apprenticeship was with Domenico Panetti. The Cremonese painter Boccaccio Boccaccino and Garofalo's two visits to Rome in the first and second decades of the century influenced his work, as did the work of Dosso Dossi, especially in the treatment of landscape backgrounds. This is clearest in several pictures of the Nativity painted before 1520; it is also apparent in the fine "Sacrifice to Ceres" (1526; National Gallery, London). Northern Italian influences, particularly from Andrea Mantegna's "Camera degli Sposi," dominate Garofalo's ceiling paintings in the Seminario at Ferrara (1519). The influence of Raphael and Michelangelo made itself felt from about 1520 onward, and Garofalo, though he seems never to have left Ferrara at this time, kept pace with the developments of Michelangelesque mannerism in Florence and Rome. This is evident in his painting the "Baptist Taking Leave of His Father" (1542) in S. Salvatore, Bologna.

**Garonne River**, Spanish **RÍO GARONA**, most important river of southwestern France, rising in the Spanish central Pyrenees and flowing into the Atlantic by way of the estuary called the Gironde. It is 357 miles (575 km) long, excluding the Gironde Estuary (45 miles in length). Formed by two headstreams in the Maladeta Massif (mountainous mass) in the Aragon region of northeast Spain, which flow from glaciers situated at elevations of more than 10,000 feet (3,000 m), the Garonne flows north for 30 miles (48 km) through Spanish territory, traversing the high mountain Val d'Aran through a gorge before crossing the frontier through the narrow defile of Pont-du-Roi at an elevation of 1,902 feet (580 m). Flowing east around Saint-Gaudens, the river veers northeast across one of the largest alluvial plains of France, receiving a tributary, the Ariège, from the southeast before passing Toulouse and then winding northward to Bordeaux. The Garonne receives the Tarn west of Moissac and is then joined by the Lot River below Aiguillon, southeast of Marmande. About 34 miles above Bordeaux it passes through Castets—its highest tidal point. At Bordeaux the river is 1,800 feet broad. Flowing between the wine-growing Entre-deux-Mers peninsula to the east and the Médoc coastal strip to the west, it unites with the Dordogne 16 miles north of Bordeaux to form the vast Gironde Estuary.

The Garonne, which is regulated by 50 locks,

is subject to sudden floods. The seasonal flow of the river is irregular, with high springtime levels at its source in the snows of the mountains, and its lowest levels in August and September. The Garonne is not navigable; it is accompanied by an old and little used lateral canal from Toulouse to Castets. The Canal du Midi, equally old, connecting the Garonne with the Mediterranean, starts at Toulouse. The river's basin is some 21,600 square miles (56,000 square km) in area.

**Garoua**, also spelled **GARUA**, town, north-eastern Cameroon, west central Africa. The town lies along the right bank of the Benue (Bénoué) River, north-northeast of Yaoundé, the national capital. It is situated at the junction of the Maroua-Ngaoundéré road and the Benue waterway and is the chief commercial centre of the region. The town was founded by Modibbo Adama, the Fulani amir who founded the kingdom of Adamawa in the first half of the 19th century. It developed as a river port. River steamers and barges bring petroleum and cement to Garoua and carry its hides, skins, cotton, and peanuts (groundnuts) 1,200 miles (1,900 km) down the Benue to Burutu, Nigeria, during the brief shipping period (August–September). Ground transportation partially replaced river transport for commerce after the construction of the railway to Douala on the Atlantic coast. Nearby cotton plantations supply Garoua's weaving factory; support its ginning, dyeing, and spinning industries; and motivate the textile research company in the town. Other industries include leatherwork, fishing, and tourism encouraged by the nearby Faro, Bénoué, and Bouba Ndjida game reserves. Garoua is served by an airfield, a hospital, a customs station, several banks and insurance companies, and a junior college. Pop. (1985 est.) 96,186.

**Garrett, João Baptista da Silva Leitão de Almeida, VISCONDE** (viscount) **DE ALMEIDA GARRETT** (b. Feb. 4, 1799, Porto, Port.—d. Dec. 9, 1854, Lisbon), writer, orator, and statesman who was one of Portugal's finest prose writers, an important playwright, and chief of the country's Romantic poets.

Garrett graduated in law from the University of Coimbra in 1820, having already gained a name for himself as a playwright and a fervent liberal. His liberalism forced him into exile in England in 1823, during which time he introduced his countrymen to the new Romantic movement with two patriotic epic poems: *Camões* (1825) and *Dona Branca* (1826).

Garrett returned to Portugal in 1832 and distinguished himself as a liberal statesman as well as a writer. In 1834 he became consul general in Brussels but returned to Portugal the following year. He entered Parliament in 1837 and soon made his mark as an orator. He was asked by the government to draw up proposals for the formation of a national theatre. He found that he had to create theatre, plays, actors, and audience to revive a native tradition that had been moribund for centuries, and to provide material for the project, he wrote a series of historical prose dramas that have become classics. Among these dramas are *Um Auto de Gil Vicente* (1838) and *O Alfageme de Santarém* (1841). Another work, *Frei Luís de Sousa* (1843), is considered one of the greatest Portuguese plays of the 19th century. An excursion Garrett took to Santarém in July 1843 resulted in a prose masterpiece describing his journey, *Viagens na Minha Terra* (1846; "Voyage to My Land"). His historical romance *O Arco de Sant'Ana*, 2 vol. (1845–50), was probably the first Romantic novel produced in Portugal.

Garrett's patriotism and service were rewarded in 1851 when he was created viscount. He served as minister for foreign affairs for a short time in 1852 and remained active in political life until his death. His other works include the verse collection *Romanceiro*, 3

vol. (1843–51), and *Folhas Caidas* (1853), a collection of short love poems whose formal elegance and sensual, melancholy tone make them the best Portuguese lyric poems of the Romantic period.

**Garrett, Pat**, byname of **PATRICK FLOYD GARRETT** (b. June 5, 1850, Chambers County, Ala., U.S.—d. Feb. 29, 1908, near Las Cruces, N.M.), Western U.S. lawman known as the man who killed Billy the Kid (*q.v.*).

Born in Alabama and reared in Louisiana, Garrett left home at about the age of 17 and headed for Texas and the life of a cowboy and buffalo hunter. In 1879 he married and settled in Lincoln County, N.M., where he became first deputy sheriff and then sheriff. In July 1881 he tracked down and shot the escaped murderer Billy the Kid.

Thereafter, Garrett was a rancher near Roswell, N.M. (1882–96), deputy sheriff and then sheriff of Dona Ana County, N.M. (1896–1902), and collector of customs at El Paso, Texas (1902–06). He then bought a horse ranch, leased it, and became involved in a heated dispute over the lease. Garrett was fatally shot on the road from the ranch to Las Cruces, N.M. The man who had leased the ranch, Wayne Brazel, alleged that Garrett had drawn a gun on him and that the killing was self-defense. A witness agreed, and Brazel went free. A suspicion lingered that Brazel or someone else conspired to execute Garrett, a lawman with many enemies.

**Garrick, David** (b. Feb. 19, 1717, Hereford, Herefordshire, Eng.—d. Jan. 20, 1779, London), English actor, producer, dramatist, poet, and comanager of the Drury Lane Theatre.

*Early years.* Garrick was of French and Irish descent, the son of Peter Garrick, a

Garrick, detail of an oil painting by Robert Edge Pine, c. 1762; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

captain in the English Army, and Arabella Clough, the daughter of a vicar choral at Lichfield cathedral who was of Irish extraction. David was born at Hereford, where his father was on recruiting duty. In the family home at Lichfield, the seven children were reared on the highest moral principles in conditions of strict economy. To obtain full pay, after several years on half pay, Captain Garrick joined an infantry regiment at Gibraltar, and David, then 14, as eldest son at home, reported family progress in lively letters that, on the whole, did credit to the Lichfield grammar school. In 1736 Gilbert Walmesley, registrar of the ecclesiastical court of Lichfield, who lived in the bishop's palace and lent his premises for private theatricals organized by his young protégé, advised that "Little Davy" should be sent to the academy opened in that year by Samuel Johnson at Edial, near Lichfield. This venture lasted only a few months, and on

March 2, 1737, Johnson and Garrick set out for London; according to Johnson, he had two-pence-halfpenny in his pocket and David three halfpence.

Garrick entered his name as a law student at Lincoln's Inn and prepared to study with a friend of Walmesley's at Rochester, Kent, but his father's death in March 1737 and a legacy of £1,000 from an uncle made possible a change of plan. David had spent some months at Lisbon as apprentice to his uncle, a vintner, and he and his elder brother set up as Garrick & Co., wine merchants—Peter at Lichfield and David in London, in Durham Yard, off the Strand. His business took him into places of entertainment, where he soon had a large acquaintance, including the actor Charles ("Wicked Charlie") Macklin, with whom he conferred on modern theories of acting, and the elegant but unreliable Charles Fleetwood, manager of Drury Lane Theatre, one of the two theatres authorized by the 1737 Licensing Act, the other being Covent Garden. In April 1740, Drury Lane produced Garrick's first comedy, *Lethe, or Esop in the Shades*.

*Beginning of career as an actor.* Garrick entered the acting profession anonymously, in a mask. In March 1741, upon the illness of the actor billed to take the part, he dashed onto the stage as Harlequin at a small, unlicensed theatre in Goodman's Fields. Soon afterward the proprietor took a company to Ipswich for the summer season, and Garrick appeared there in Thomas Southerne's *Oroonoko* as Aboan, a noble savage, with his face blackened, and later played Captain Duretête, in George Farquhar's *The Inconstant*. He was thereafter well received in several parts, but when he applied at Drury Lane and Covent Garden, neither Fleetwood nor old John Rich, manager of Covent Garden, wanted him. He had to return to Goodman's Fields. His mother had died in 1740, but he still dared not tell his family that he had entered a profession then generally held in low esteem. Not until the night after his astounding first appearance as Richard III in 1741 did he break the news to Peter.

The instant success of a young, unknown actor in a major tragic Shakespearean part remains one of the romances of theatrical history. The Garrick legend was founded in a single night. Audiences, weary of the pompous recitative and stately attitudinizing imposed by French tradition, were ready for the naturalistic new style, and they soon perceived that this bright young man could do anything. He was equally good in *Pamela*, a dramatization of Samuel Richardson's novel; in Thomas Otway's *The Orphan and Venice Preserv'd*; in Colley Cibber's *Love Makes a Man*; or *The Pop's Fortune*; in *King Lear*; and in a farce he himself wrote, *The Lying Valet*. He wrote to Peter: "Mr. Pit, who is reckon'd ye Greatest Orator in the house of Commons, said I was ye best actor ye English stage had produc'd." Alexander Pope had pronounced: "That young man never had his equal an actor, and he will never have a rival." Thomas Gray wrote to Horace Walpole that a dozen dukes a night attended Goodman's Fields. So much adulation, so easily won, might have demoralized a less stable character, but Garrick, though highly strung and sensitive, had a strong vein of common sense and remarkable staying power.

Fleetwood was now eager to secure him for Drury Lane and offered a salary larger than ever proposed to any performer. Before the season of 1742–43 Garrick went over to Dublin where he played at the theatre in Smock Alley with the captivating Peg Woffington, with whom he was already in love, and whom he hoped to marry. There, his success was tremendous, and he continued to triumph at Drury Lane from 1742–45, playing such diverse roles as Hamlet; the

simple-minded Abel Drugger in Ben Jonson's *The Alchemist*; and the voluble Francis Archer in George Farquhar's *The Beaux' Stratagem*. But Fleetwood's patent of the theatre was running out, and he was a ruined man. In 1743 Garrick sued him for £600 arrears of salary and led an actor's strike against him, one side effect of which was a quarrel with Macklin. A reconciliation was arranged in 1747, but Macklin's senile mutterings, noted down by his biographer, became the fountainhead of the anti-Garrick legends of vanity, avarice, meanness, and arrogance.

In the winter of 1745–46 Garrick was in Dublin, sharing with Thomas Sheridan, the playwright and actor-manager, in the direction of the Theatre Royal. During this time negotiations began for Garrick to become part owner and manager of Drury Lane Theatre. In the season of 1746–47 Garrick made his only appearances at Covent Garden. John Rich had also secured James Quin, the outstanding exponent of the old style of acting, and the season became a duel between them.

*Reforms of Drury Lane Theatre.* In April of 1747 friends in the city helped Garrick to raise £8,000, his share of the purchase money for the lease and furnishings of Drury Lane Theatre and renewal of the patent, in partnership with one James Lacy, a failed actor with a flair for the entertainment trade, who had been stage manager at Covent Garden. Garrick was to perform and to choose plays and players; Lacy, assisted by a weakish, devoted younger Garrick, "Brother George," dealt with the business side. Drury Lane, redecorated, reopened in September 1747 with Macklin as Shylock and a prologue by Johnson that set forth Garrick's principles, as a producer, of devotion to Shakespeare and reform of plays and players and ending with the famous appeal:

The drama's laws the drama's patrons give,  
For we, who live to please, must please to live.  
... 'Tis yours this night to bid the reign commence

Of rescued nature and reviving sense.

Garrick was unwell, however. He had endured many minor ailments, indicative of overstrain, in the past months, during which he had never acted more poignantly. The infidelities and extravagance of Peg Woffington had convinced him that they had better not marry. He had announced to his brilliant new troupe that they would find his rule stricter than any to which they were accustomed. Among his stars were Macklin, Woffington, and Kitty Clive, the only actress of whom he was said to be afraid, but one who was to become a dear friend.

He had made plans for reforming audiences as well as actors. He was going to try refusing admittance behind the scenes and on the stage and discontinuing the practice of reduced entry fees for those who left early or came late. He planned to bring down the orchestra from the gallery and to enlarge the auditorium. The apron, a forestage in front of the curtain onto which players marched, struck a pose, and took up their stances for lengthy soliloquies, became obsolete with the new, natural style of acting. Garrick hoped to introduce new lighting, but not until 1765 did he get his footlights and sidelights, which were oil lamps with reflectors.

Most important was to be his choice of plays and manner of production. He was going to produce much more Shakespeare, purged of the coarse language and effects of Restoration drama: the name of Garrick should be remembered with that of Shakespeare. He would add a death scene between Romeo and Juliet but restore much of the original text lost in adaptations by the Restoration playwrights, Thomas Otway and Colley Cibber. He would present Nahum Tate's 1681 adaptation of *King Lear*, without the Fool and with a happy ending,

and give *The Fairies (A Midsummer Night's Dream)* without the clownish artisans and *Hamlet* without the gravediggers and the tragic fate of Ophelia. *Florizel and Perdita* (adapted from *The Winter's Tale*) and Dryden's version of *The Tempest* would make charming light operas. He would rewrite *The Taming of the Shrew*, adapting the role of Katherina for Kitty Clive. In general, his audiences, accustomed to rewritings of Shakespeare, accepted his "improvements" with docility: they at least had the merit of keeping the plays on the stage by suiting them to the taste of the time. Moreover, Garrick's acting and casting often succeeded in interpreting character in a way closer to Shakespeare and new to the audience.

On June 22, 1749, Garrick married Eva Maria Veigel, a Viennese opera dancer who spoke little English and was a devout Roman Catholic. Under the stage name of La Violette, she had enchanted audiences at the Opera House in the Haymarket in 1746, and, although she had refused to dance for Garrick at Drury Lane in 1748, the following year she consented to retire and thereafter to attempt only one role, that of Mrs. Garrick. The marriage, though childless, was happy, and the Garricks' hospitality became famous.

*Successes and setbacks.* At Drury Lane, Garrick went from strength to strength. He had already appeared in most of the parts in which he was best liked, and he realized with good humour that, as he was slightly below middle height and had put on weight, he had better give up youthful characters and add to his fame in the more mature roles—Abel Drugger, King Lear, Macbeth, Richard III. His mobile features, dark complexion, and eyes—widely praised for their lustre, expressiveness, and piercing brilliance—were famous on and off stage. In search of "copy," he frequented the law courts and House of Commons and would even visit the scene of a family tragedy. Critics disagreed as to whether he excelled in tragedy or comedy. He himself once told a young aspirant that comedy called for the greater skill.

Though he raised Drury Lane Theatre from penury to astounding financial success and, by his improvements in 1747–48 and 1762 and by the acting of his company, had made it London's most flourishing theatre, he had his setbacks. He burdened his players with some deadly historical and classical tragedies. He could turn disaster to success, however. When his theatre was wrecked by hooligans in November 1755, he faced a hostile house with courage. When in 1769 preternaturally wet weather washed out his cherished Shakespeare Jubilee at Stratford-on-Avon, he refurbished both costumes and script for London, played *The Jubilee* to packed houses, and emerged with a profit. He was accused of avarice—though his inconspicuous charities were many—and was laughed at for his vanity and love of staying at great houses. He was involved in a succession of "paper wars" with touchy and even slanderous disappointed writers and players, such as Charles Churchill, who praised and attacked him, and Samuel Foote, who ridiculed the extravagant Shakespeare Jubilee. Garrick's caricatures of fellow actors in the Duke of Buckingham's *The Rehearsal* in his early days gave wide offense. His rivalry with Rich, at Covent Garden, was sometimes acrimonious; sometimes it led to new success. Rich had prided himself on his Christmas pantomimes; Garrick's, with superb effects and lighting by Philip James de Louthborough, a young expert in scenic design of Polish descent, far surpassed them. For his own spectacular "Christmas gambol," *Harlequin's Invasion* (1759), with music by William

Boyce, he wrote the patriotic song, "Heart of Oak."

Though "Heart of Oak" is perhaps the only poem by which he is remembered, his quality as a poet is shown by songs added to plays and by verses to Peg Woffington (the early ones those of a young man deeply in love, the bitter "Epistle to Mrs. Woffington" of 1745 exposing "the naked truth") and to his wife. As a dramatist (he wrote more than 20 plays and "entertainments" and adapted many more), he suffers from having written for a particular company and audience; and his farces and burlesques, though lively, have not held the stage. Only *The Claretine Marriage* (1766), written with George Colman the Elder, is still successfully revived. His letters, however, have lasting interest. All of his life a prolific letter writer, he wrote as he acted, with ease, spontaneity, and versatility. His letters are a valuable source for the details of his busy life, the tangled theatrical history of his time, and his character and outlook.

*Last years.* In 1763 the Garricks departed for a continental tour. They enjoyed sight-seeing in Italy in aristocratic company, but Mrs. Garrick suffered agonies from what was, apparently, a slipped disk, and Garrick contracted typhoid in Venice and nearly died in Munich. They wintered in Paris, where Garrick enlarged his acquaintance with French literary and theatrical celebrities, Shakespearean enthusiasts, and the philosophes. After returning (spring 1765), he appeared in no new parts, but 10 years passed before he prepared to sell his share of the Drury Lane patent. A series of farewell performances included four Shakespearean parts: Benedick, Hamlet, Richard III, and Lear; Abel Drugger; Sir John Brute from Sir John Vanbrugh's *The Provok'd Wife*; Archer from *The Beaux' Stratagem*; and, for his last performance, Don Felix from Susannah Centlivre's *The Wonder: A Woman Keeps a Secret*.

Garrick's retirement was happy. In London he was a member of Johnson's Literary Club and Brooks's. At Hampton he had his duties as squire, his library and garden, his dogs, and his nieces and nephews. All of his life a sufferer from kidney trouble, he was taken ill while staying with his old friends Lord and Lady Spencer at Althorp Park, Northamptonshire, for the New Year, 1779, and died at his house in Adelphi Terrace shortly thereafter.

Garrick was buried in the Poets' Corner, Westminster Abbey; a monument in Lichfield cathedral bears Johnson's famous "I am disappointed by that stroke of death that has eclipsed the gaiety of nations, and impoverished the public stock of harmless pleasure."

(C.O.)

**MAJOR WORKS.** *Lethe; or, Esop in the Shades* (1740); *The Lying Valet* (1741); *Miss in Her Teens; or, The Medley of Lovers* (1741); *Lilliput* (1756); *The Male Coquette; or, Seventeen Fifty Seven* (1757); *The Guardian* (1759); *Harlequin's Invasion* (1759); *The Enchanter; or, Love and Magic* (1760); *The Farmer's Return from London* (1762); *The Claretine Marriage* (1766; with George Colman the Elder); *Neck or Nothing* (1766); *Cymon* (1767); *Linco's Travels* (1767); *A Peep Behind the Curtain, or The New Rehearsal* (1767); *The Jubilee* (1769); *The Irish Widow* (1772); *A Christmas Tale* (1773); *The Meeting of the Company; or, Bayes's Art of Acting* (1774); *Bon Ton; or, High Life Above Stairs* (1775); *The Theatrical Candidates* (1775); *May-Day; or, The Little Gypsy* (1775).

**BIBLIOGRAPHY.** For Garrick's life the chief source other than contemporary accounts is his own correspondence: *The Letters of David Garrick*, ed. by David M. Little and George M. Kahrl, 3 vol. (1963), which also includes an excellent short biography by Kahrl. Early biographies include Thomas Davies, *Memoirs of the Life of David Garrick*, 2 vol. (1780; rev. ed. 1808, reprinted

1972), a solemn but popular study by a man who knew Garrick; Arthur Murphy, *The Life of David Garrick*, 2 vol. (1801, reprinted 1969), a racy and anecdotal study; Percy Fitzgerald, *The Life of David Garrick*, 2 vol. (1868, reprinted 1971); Florence Parsons, *Garrick and His Circle* (1906, reprinted 1969); Frank Hedgcock, *A Cosmopolitan Actor* (1912, reprinted 1969); Joseph Knight, *David Garrick* (1912, reprinted 1969); Elizabeth P. Stein, *David Garrick* (1938, reprinted 1967); and Margaret Barton, *Garrick* (1949, reprinted 1978). Carola Oman, *David Garrick* (1958); and George W. Stone, Jr., and George M. Kahrl, *David Garrick* (1979), are more recent full-length biographies. George Pierce Baker and David M. Little edited separately more than 100 unpublished letters, in 1907 and 1930; and R.C. Alexander in 1928, the long-missing Paris 1751 *Diary of David Garrick*.

**Garrison, William Lloyd** (b. Dec. 10/12, 1805, Newburyport, Mass., U.S.—d. May 24, 1879, New York City), U.S. journalistic crusader who published a newspaper, *The Liberator* (1831–65), and helped lead the successful Abolitionist campaign against slavery in the United States.

Garrison

By courtesy of the Library of Congress, Washington, D.C.

Garrison was the son of an itinerant seaman who subsequently deserted his family. The son grew up in an atmosphere of declining New England Federalism and lively Christian benevolence—two sources of the Abolitionist movement, which he joined at the age of 25. As editor of the *National Philanthropist* (Boston) in 1828 and the *Journal of the Times* (Bennington, Vt.) in 1828–29, he served his apprenticeship in the moral reform cause. In 1829, with a pioneer Abolitionist, Benjamin Lundy, in Baltimore, he became co-editor of the *Genius of Universal Emancipation*; he also served a short term in jail for libelling a Newburyport merchant who was engaged in the coastal slave trade. Released in June 1830, Garrison returned to Boston and, a year later, established *The Liberator*, which became known as the most uncompromising of American anti-slavery journals. In the first issue of *The Liberator* he stated his views on slavery vehemently: "I do not wish to think, or speak, or write, with moderation. . . . I am in earnest—I will not equivocate—I will not excuse—I will not retreat a single inch—AND I WILL BE HEARD."

Like most of the Abolitionists he recruited, Garrison was a convert from the American Colonization Society, which advocated the return of free blacks to Africa, to the principle of "immediate emancipation," borrowed from English Abolitionists. "Immediatism," however variously it was interpreted by American

reformers, condemned slavery as a national sin, called for emancipation at the earliest possible moment, and proposed schemes for incorporating the freedmen into American society. Through *The Liberator*, which circulated widely both in England and the United States, Garrison soon achieved recognition as the most radical of American anti-slavery advocates. In 1832 he founded the New England Anti-Slavery Society, the first immediatist society in the country, and in 1833 he helped organize the American Anti-Slavery Society, writing its Declaration of Sentiments and serving as its first corresponding secretary. It was primarily as an editorialist, however, excoriating slave owners and their moderate opponents alike, that he became known and feared. "If those who deserve the lash feel it and wince at it," he wrote in explaining his refusal to alter his harsh tone, "I shall be assured that I am striking the right persons in the right place."

In 1837, in the wake of financial panic and the failure of Abolitionist campaigns to gain support in the North, Garrison renounced church and state and embraced doctrines of Christian "perfectionism," which combined Abolition, women's rights, and nonresistance, in the biblical injunction to "come out" from a corrupt society by refusing to obey its laws and support its institutions. From this blend of pacifism and anarchism came the Garrisonian principle of "No Union With Slaveholders," formulated in 1844 as a demand for peaceful Northern secession from a slaveholding South.

By 1840 Garrison's increasingly personal definition of the slavery problem had precipitated a crisis within the American Anti-Slavery Society, a majority of whose members disapproved of both the participation of women and Garrison's no-government theories. Dissension reached a climax in 1840, when the Garrisonians voted a series of resolutions admitting women and thus forced their conservative opponents to secede and form the rival American and Foreign Anti-Slavery Society. Later that year a group of politically minded Abolitionists also deserted Garrison's standard and founded the Liberty Party. Thus, 1840 witnessed the disruption of the national organization and left Garrison in control of a relative handful of followers loyal to his "come-outer" doctrine but deprived of the support of new anti-slavery converts and of the Northern reform community at large.

In the two decades between the schism of 1840 and the Civil War, Garrison's influence waned as his radicalism increased. The decade before the war saw his opposition to slavery and to the federal government reach its peak: *The Liberator* denounced the Compromise of 1850, condemned the Kansas-Nebraska Act, damned the Dred Scott decision, and hailed John Brown's raid as "God's method of dealing retribution upon the head of the tyrant." In 1854 Garrison publicly burned a copy of the Constitution at an Abolitionist rally in Framingham, Mass. Three years later he held an abortive secessionist convention in Worcester, Mass.

The Civil War forced Garrison to choose between his pacifist beliefs and emancipation. Placing freedom for the slave foremost, he supported Abraham Lincoln faithfully and in 1863 welcomed the Emancipation Proclamation as the fulfillment of all his hopes. Emancipation brought to the surface the latent conservatism in his program for the freedmen, whose political rights he was not prepared to guarantee immediately. In 1865 he attempted without success to dissolve the American Anti-Slavery Society and then resigned. In December 1865 he published the last issue of *The Liberator* and announced that "my vocation as an abolitionist is ended." He spent his last 14 years in retirement from public affairs, regularly supporting the Republican Party and

continuing to champion temperance, women's rights, pacifism, and free trade. "It is enough for me," he explained in justifying his refusal to participate in radical equalitarian politics, "that every yoke is broken, and every bondman set free." (J.L.T.)

**BIBLIOGRAPHY.** The standard biography is Wendell P. and Francis J. Garrison, *William Lloyd Garrison, 1805–1879: The Story of His Life Told by His Children*, 4 vol. (1885–89). Still useful are two contemporary accounts by Oliver Johnson, *William Lloyd Garrison and His Times* (1879); and by Samuel J. May, *Some Recollections of Our Antislavery Conflict* (1869); as well as the sympathetic neo-abolitionist essay by John Jay Chapman, *William Lloyd Garrison* (1913). Later estimates include Russell B. Nye, *William Lloyd Garrison and the Humanitarian Reformers* (1955); Walter M. Merrill, *Against Wind and Tide: A Biography of William Lloyd Garrison* (1963); and John L. Thomas, *The Liberator, William Lloyd Garrison* (1963).

**Garrod, Dorothy Annie Elizabeth** (b. May 5, 1892, London, Eng.—d. Dec. 18, 1968, Cambridge, Cambridgeshire), English archaeologist who directed excavations at Mount Carmel, Palestine (1929–34), uncovering skeletal remains of primary importance to the study of human evolution.

Garrod carried out Paleolithic, or Old Stone Age, research in Gibraltar (1925–26) and in southern Kurdistan (1928). From 1929 to 1934 she led joint British and American efforts at Mount Carmel that brought to light the first evidence of Paleolithic and Mesolithic, or Middle Stone Age, cultures in Palestine. During 1931–32 some dozen skeletal remains were found in a cave and rock shelter, including, from the cave, a complete female skeleton now known to be about 41,000 years old. The remains from the rock shelter are about 5,000 years younger. Some authorities believe that these remains represent an intermediate stage between Neanderthal man and modern man. Findings were published in *The Stone Age of Mount Carmel*, 2 vol. (1937–39). She turned to Stone Age studies in Bulgaria in 1938. A leading authority on the Paleolithic for many years, Garrod was the first woman to receive a professorship at the University of Cambridge, serving as professor of archaeology from 1939 to 1952. She conducted research in southern Lebanon in 1958.

**Garros, Pey de** (b. c. 1530, Lectoure, near Agen, France—d. 1585, Pau), Provençal poet whose work raised the Gascon dialect to the rank of a literary language in 16th-century France.

A Protestant, Garros studied law, theology, and Hebrew at the University of Toulouse and later became *avocat-général* of Pau. In the preface to his *Poesias gasconas* (1567; "Gascon Poetry") he chided his fellow countrymen for preferring French to Gascon and pleaded for a restoration of the native dialect. He published a rhymed Gascon translation of the Psalms of David (1565). His *Églogues* go beyond the imitation of classical models, attempting to capture the true flavour of Gascon peasant life.

**garrote**, device used in strangling condemned persons. In one form it consists of an iron collar attached to a post. The victim's neck is placed in the collar, and the collar is slowly tightened by a screw until asphyxiation occurs. Another form of garrote is a length of wire with wooden handles at the ends, held by the executioner.

**Garrya**, genus of about 15 species of shrubs or small trees, constituting the family Garryaceae, and native to the western United States and Mexico, with one species occurring in the West Indies. The young branches of these plants are four-sided. Male and female flowers are on separate plants and grow in catkinlike flower clusters (the only genus in the order Cornales with such a flower cluster). *G. elliptica*,

*Garrya elliptica*  
G.E. Nicholson

*tica*, an early flowering species, is occasionally grown as an ornamental.

**Garshin, Vsevolod Mikhaylovich** (b. Feb. 2 [Feb. 14, New Style], 1855, Bakhmutsy district, Russian Empire—d. March 24 [April 5], 1888, St. Petersburg), Russian short-story writer whose works helped to foster the vogue enjoyed by that genre in Russia in the late 19th century.

Garshin was the son of an army officer whose family was wealthy and landed. The major Russo-Turkish war of the 19th century broke out when Garshin was in his early twenties, and, perhaps feeling obligated by his father's profession, he renounced his youthful pacifism to serve.

He wrote of the plight of injured soldiers in his first story, "Chetyre dnya" (1877; "Four Days"), the title of which refers to the length of time the wounded main character remains unattended on the battlefield. The theme of wartime casualty is continued in his "A Very Short Novel," the story of a soldier whose injury precipitates an emotional crisis when he returns home. In perhaps his most famous story, "Krasny tsvetok" (1883; "The Red Flower"), a madman dies after destroying a flower he believes to contain all of the world's evil. Haunted by similar delusions in his own life, Garshin committed suicide by throwing himself down a stairwell.

**Garstang, John** (b. May 5, 1876, Blackburn, Lancashire, Eng.—d. Sept. 12, 1956, Beirut, Lebanon), English archaeologist who made major contributions to the study of the ancient history and prehistory of Asia Minor and Palestine.

Best known for his excavation of Jericho (1930–36), Garstang entered the field of archaeology by excavating Roman remains in Britain, notably at Ribchester, Lancashire. For about 40 years he successfully combined fieldwork with an academic career. He became a lecturer in Egyptian archaeology at the University of Liverpool (1902), where he served as professor of methods and practice of archaeology from 1907 to 1941.

His work in Egypt, first at Abydos with the famed English archaeologist Flinders Petrie (1900), continued through 1908 and included excavation of a number of sites. During a visit to the excavation of the Hittite capital at Hattusas (now Boğazköy, Turkey), he witnessed the discovery of the Hittite royal archives, and

a major aspect of his career thus was launched. While carrying out research in northern Syria and Anatolia, he decided to excavate a mound near Sakkagöz, Turkey. Between 1907 and 1911 a wealth of discoveries were made there, from architectural remains and sculpture of the late Hittite period to Neolithic pottery and implements of the 5th and 4th millennia BC. In 1910 he published *The Land of the Hittites*. From 1909 to 1914 he directed much attention to the northern Sudan, excavating ancient Meroe and the nearby temple of the sun, analyzing this work in *Meroë: The City of the Ethiopians* (1911).

Garstang became the first director of the British School of Archaeology in Palestine in 1919, where he developed plans for systematic archaeological surveys. He studied a number of sites, including that of Ascalon (present-day Ashqelon), near Gaza, where he found evidence of habitation dating back to 2000 BC. His excavation of places associated with the passing of the Israelites into Canaan aroused considerable interest and support. In 1926, near the Sea of Galilee, he identified Hazor of the Bible. From 1930 to 1936 he worked at Jericho and made the first soundings to reach very early strata that antedated the use of pottery. Though he related some fallen city walls to Joshua's conquest, later research indicated that they date from three centuries earlier. Nevertheless, his book *The Foundations of Bible History: Joshua, Judges* (1931) remains a valuable source of information.

In 1937 he again turned his attention to the land of the Hittites. Choosing Yümük Tepesi, near Mersin, Turkey, as his site, he found many valuable prehistoric remains. He became director of the British Institute of Archaeology in Turkey (1947) and published the results of his last major effort in *Prehistoric Mersin* (1953).

**Garter, The Most Noble Order of the**, English order of knighthood founded by King Edward III in 1348, considered to be the highest British civil and military honour obtainable. Because the earliest records of the order were destroyed by fire, it is difficult for historians to reconstruct its original purposes, the significance of its emblem, and the origin of the order's motto. One theory is that Edward III wished to revive the Round Table of Arthurian legend, thereby creating a fraternity of knights, and that the garter perhaps symbolized the homage paid by knights to ladies.

According to the most picturesque legend, it was established to commemorate an incident in which Edward was dancing with Joan of Kent, Countess of Salisbury, when one of her blue garters dropped to the floor. As bystanders snickered, Edward gallantly picked up the garter and put it on his own leg, admonishing the courtiers in French with the phrase that remains as the order's motto "*Honi soit qui mal y pense*" ("Shame to him who thinks evil of it," or, more popularly, "Evil to him who evil thinks"). The king inaugurated the order with a great feast and a memorable joust.

As one of the most distinguished and exclusive orders of knighthood, the order's roster has contained many illustrious names. The original medieval membership consisted of the British sovereign and the prince of Wales, each with 12 companions, as if at a tournament. In 1805 the number of knights companions was expanded to 25, the number it maintains today. Membership was expanded in the late 18th and early 19th centuries to include supernumeraries such as members of the royal family (known as "royal knights companions"), lineal descendants of George I and George II, and foreigners (known as "extra knights"). The British sovereign and prince of

Wales are always members of the order. Originally, existing knights elected new knights, but now appointment to the order is solely at the discretion of the British monarch. Women have been made ladies of the order, but they are not ranked among the 25 knights companions.

Conferment of the order entails adoption into knighthood and the right to use the title "Sir." Holders of the order can add K.G. (Knight of the Garter) after their names. The order has five officers: prelate (who is always the bishop of Winchester), chancellor, registrar (dean of Windsor since Charles I's reign), Garter king of arms, and gentlemen usher of the Black Rod.

As St. George is the patron saint of the order, April 23 (St. George's Day) is its feast day. The chapel of the order is St. George's Chapel, Windsor Castle. Each knight has a stall assigned to him in this chapel; placed in it are his banner, helmet, and stallplate bearing his coat of arms. The banner and helmet are taken down after the death of a knight, but the stallplate remains permanently fixed in the stall of the chapel (the oldest plate of arms is from c. 1394). As a result of this arrangement, the stalls of St. George's Chapel provide one of the most excellent examples known of the history of heraldic design.

The insignia comprise the garter with the motto emblazoned on it, the star with St. George's cross, and a collar with a badge representing St. George and the dragon. All insignia must be returned on the death of the holder.

**garter snake**, any of more than a dozen species of snakes constituting the genus *Thamnophis*, in the family Colubridae. They have a striped pattern suggesting a garter: typically, one or three longitudinal yellow or red stripes, between which are checkered blotches. Forms in which the stripes are obscure or lacking are often called grass snakes. Authorities differ as to the number of species, since garter snakes show only slight differences in scalation but considerable geographic differences in coloration. From Canada to Central America they are among the commonest serpents: every vacant lot harbours a few, and the name garden snake is appropriate. Western forms are more water-loving than eastern forms.

Garter snakes are small—usually under 60 cm (24 inches) long—and quite harmless. If disturbed they usually hide the head and writhe the tail while discharging a foul secretion from the anal gland; some will strike. Among the more aggressive forms is the common garter snake (*Thamnophis sirtalis*), North America's most widely distributed reptile. The ribbon snake (*T. sauritus*), small and slender, is a strongly striped form. Garter snakes live

Garter snake (*Thamnophis*)  
Leonard Lee Rue III

chiefly on insects, earthworms, and amphibians; the ribbon snake is especially fond of frogs. All are rather gregarious before breeding and before hibernating.

**Gartok**, Chinese (Wade-Giles) KA-ERH-TU, KA-TA-K'O, or (Pinyin) GARYARSA, town in the Tibetan autonomous *ch'ü* (region), western China. It is located at an elevation of 14,630 feet (4,460 m) at the foot of the Kailas Range on the Gar (Ka-erh) River, which is one of the headwaters of the Yin-tu (Indus) River. Gartok is an important route centre on the main road through the southern Tibetan region from Lhasa, the capital of Tibet, to Jammu and Kashmir. Historically Gartok was an important trade centre for traveling merchants from India and Nepal, who attended the great fairs held there.

In the 18th century Gartok, on the frontier of the then-independent kingdom of Ladakh, was a major military garrison. Gartok was formally opened to foreign trade following the Lhasa Treaty (between the United Kingdom and Tibet) of 1904. The ruins of ancient fortifications still survive, but in the 1930s there was no town there, merely the residence of the Tibetan governor and a small temple. Since the Chinese occupation of Tibet in 1959, the area has been the scene of considerable road building to provision the Ladakh border area to the south and west. Pop. (mid-1980s est.) fewer than 10,000.

**Garua** (Cameroon): see Garoua.

**Garuḍa**, in Hindu mythology, the bird and the *vāhana* (mount) of the god Vishnu. In the *R̥gveda* (a collection of Vedic hymns) the sun

Garuḍa carrying Vishnu and Lakṣmi, bronze image from South India, 18th century; in the Guimet Museum, Paris  
Cliche Musees Nationaux, Paris

is compared to a bird in its flight across the sky, and the association of the kitelike Garuḍa with Vishnu is taken by scholars as another indication of Vishnu's early origins as a sun deity. The mythological account of Garuḍa's birth identifies him as the younger brother of Aruṇa, the charioteer of the sun god, Surya. His mother was held in slavery by her co-wife and her sons, who were nagas (serpents), to which is attributed the lasting enmity between the eaglelike kite and the serpents. The nagas agreed to release his mother if he could obtain for them a drink of the elixir of immortality, the *amṛta*. Garuḍa performed this feat with a certain amount of difficulty and on his way back from the heavens met Vishnu and agreed to serve him as his vehicle and also as his emblem.

Garuḍa is described in one text as emerald in colour, with the beak of a kite, roundish eyes, golden wings and four arms, and with breast, knees, and legs like those of the kite. He is also depicted anthropomorphically, with

wings and hawklike features. Two of his hands are folded in adoration (*añjali-mudrā*) and the other two carry an umbrella and the pot of *amṛta*. Sometimes Vishnu rides on his shoulders. Images of Garuḍa are used by devotees of Vishnu to designate their cult affiliations, in which guise they appeared on coins of the Gupta period.

Garuḍa traveled with the spread of Hinduism to Nepal and to Southeast Asia, where he is frequently depicted on monuments. He is also associated with royalty in several Southeast Asian countries.

**Garvey, Marcus (Moziah)** (b. Aug. 17, 1887, St. Ann's Bay, Jamaica—d. June 10, 1940, London, Eng.), charismatic black leader

Garvey, 1922  
UPI

who organized the first important American black nationalist movement (1919–26), based in New York City's Harlem.

Largely self-taught, Garvey attended school in Jamaica until he was 14. After traveling in Central America and living in London from 1912 to 1914, he returned to Jamaica, where, with a group of friends, he founded (Aug. 1, 1914) the Universal Negro Improvement and Conservation Association and African Communities League, usually called the Universal Negro Improvement Association (UNIA), which sought, among other things, to build in Africa a black-governed nation.

Failing to attract a following in Jamaica, Garvey went to the United States (1916) and soon established branches of the UNIA in Harlem and the other principal ghettos of the North. By 1919 the rising "Black Moses" claimed a following of about 2,000,000, though the exact number of association members was never clear. From the platform of the Association's Liberty Hall in Harlem, he spoke of a "new Negro," proud of being black. His newspaper, *Negro World*, told of the exploits of heroes of the race and of the splendours of African culture. He taught that blacks would be respected only when they were economically strong, and he preached an independent black economy within the framework of white capitalism. To forward these ends, he established the Negro Factories Corporation and the Black Star Line (1919), as well as a chain of restaurants and grocery stores, laundries, a hotel, and a printing press.

He reached the height of his power in 1920, when he presided at an international convention in Liberty Hall, with delegates present from 25 countries. The affair was climaxed by a parade of 50,000 through the streets of Harlem, led by Garvey in flamboyant array.

His slipshod business methods, however, and his doctrine of racial purity and separatism (he even approved of the white racist Ku Klux Klan because it sought to separate the races) brought him bitter enemies among estab-

lished black leaders, including labour leader A. Philip Randolph and W.E.B. Du Bois, head of the National Association for the Advancement of Colored People (NAACP). Garvey's influence declined rapidly when he and other UNIA members were indicted for mail fraud in 1922 in connection with the sale of stock for the Black Star Line. He served two years of a five-year prison term, but in 1927 his sentence was commuted by Pres. Calvin Coolidge, and he was deported as an undesirable alien. He was never able to revive the movement abroad, and he died in virtual obscurity. Edmund David Cronon's biography *Black Moses* appeared in 1955.

**Gary**; city, Lake county, extreme northwest Indiana, U.S., at the southern end of Lake Michigan in the Calumet district east of Chicago. In 1906 the town (named for Elbert H. Gary, chief organizer of the United States Steel Corporation) was laid out as an adjunct of the company's vast new manufacturing complex. The site was chosen because it lay on navigable water midway between the iron ore beds to the north and the coal region to the south. Large areas were drained, a meandering river was rerouted, and sand dunes were removed. Steelworks were then built along the lake shore, with the city to the south. The Gary Land Company, a U.S. Steel subsidiary, laid out its part of the city, constructed the streets and sidewalks, installed the sewage system, and built the waterworks and electric plant. The first blast furnace was fired in December 1908, and steel production began early the following year. Although Gary has some diversified manufacturing, it is essentially a one-industry city and has periodically suffered from declines in steel production and labour disputes. During World War I a sizable number of blacks came to work in Gary and comprised one-sixth of the population in the 1930s. World War II drew many more, and in 1967 Richard G. Hatcher was one of the first blacks to be elected mayor of a major U.S. city. Gary was the scene of a significant early 20th-century development in public education when William A. Wirt established the work-study-play school, popularly known as the platoon school, designed to attract underprivileged children. Construction of a new civic centre in the city's downtown area was begun in 1979. Gary is the seat of Indiana University Northwest (1933). Inc. town. 1906; city. 1909. Pop. (1990) city, 116,646; Gary-Hammond PMSA, 604,526.

**Gary, Elbert Henry** (b. Oct. 8, 1846, near Wheaton, Ill., U.S.—d. Aug. 15, 1927, New York City); U.S. jurist and chief organizer of the United States Steel Corporation.

In 1871 Gary entered law practice in Chicago. He served as judge of Du Page County, Ill., from 1882 to 1890 and was president of the Chicago Bar Association from 1893 to 1894.

Elbert H. Gary  
U.S. Steel Photo

A leader and an authority in corporate law and the insurance business, Gary became general counsel and a director in a number of

large railroads, banks, and industrial corporations. In 1898 he became the first president of the newly organized Federal Steel Company, which was backed by the financier J.P. Morgan. Federal Steel merged with the U.S. Steel Corporation in 1901. Gary was elected chairman of the board of directors and was the corporation's chief executive officer during 26 years of remarkable development and growth of the steel industry.

As chairman of U.S. Steel, Gary helped improve the workers' conditions by promoting stock ownership and profit sharing by the employees, higher wages, and safe, sanitary working conditions. He was a firm advocate of the open shop, however, and his unwillingness to negotiate that issue led to the steel strike of 1919–20. The strike forced him to give his support to abolishing the 7-day week and the 12-hour day in the steel mills. The town of Gary, Ind., named in his honour, was laid out in 1906 by U.S. Steel.

**Gary, Romain**, original name ROMAIN KACEW (b. May 8, 1914, Vilnius, Lithuania, Russian Empire—d. Dec. 2, 1980, Paris), French novelist whose first work, *L'Éducation européenne* (1945; *Forest of Anger*, 1944), won him immediate acclaim. Humanistic and optimistic despite its graphic depictions of the horrors of World War II, the novel was later revised and reissued in English as *Nothing Important Ever Dies* (1960).

Gary's novels mix humour with tragedy and faith with cynicism. *Les Couleurs du jour* (1952; *The Colors of the Day*, 1953), set in Nice at carnival, and *La Danse de Genghis Cohn* (1967; *The Dance of Genghis Cohn*, 1968), in which the ghost of a Jewish stand-up comedian takes possession of his Nazi executioner, are comic novels nonetheless informed by serious moral considerations. *Les Racines du ciel* (1956; *The Roots of Heaven*, 1958), winner of the Prix Goncourt, balances a visionary conception of freedom and justice against a pessimistic comprehension of man's cruelty and greed. Other works by Gary include *Le Grand Vestiaire* (1948; *The Company of Men*, 1950), a novel set in postwar Paris; *Lady L* (French and English versions, 1959), a social satire; *La Promesse de l'aube* (1960; *Promise at Dawn*, 1962), an autobiography; *Clair de femme* (1977; "The Light of a Woman"); and *Les Cerf-volants* (1980; "The Kite").

During World War II Gary joined Gen. Charles de Gaulle in London. Already trained as an aviator, he served with the Free French Forces in Europe and North Africa, earning the Croix de Guerre and Compagnon de la Libération. For 20 years following the war, he served in French diplomatic service. From 1956 to 1960 he was French consul general in Los Angeles.

**Garyān** (Libya): see Gharyān.

**gas**, one of the three fundamental states of matter. It has distinctly different properties from the liquid and solid states.

A brief treatment of gas follows. For full treatment, see MACROPAEDIA: Matter: Its Properties, States, Varieties, and Behaviour.

A gas has no definite shape and exhibits high fluidity. It tends to expand indefinitely and readily fills any container into which it is introduced. Gases are highly compressible, and under ordinary conditions they have a density approximately 1,000 times less than that of liquids. A small change in temperature or pressure generally produces a substantial change in the volume of a gas. The relationships between the temperature, pressure, and volume of gases have been deduced and expressed in the form of equations known as the gas laws (see Boyle's law; Charles's law; Avogadro's law).

Gases were studied as early as antiquity, but an understanding of the gaseous state, as of the other basic states of matter, came only

with the development of the kinetic molecular theory in the 19th century. According to this theory, all matter is composed of particles (atoms or molecules or mixtures of both) in constant motion. In a gas, the particles are far enough apart and are moving fast enough to escape each other's influence (e.g., attraction or repulsion due to electrical charges). The freely moving particles constantly collide with one another, but the collisions result in no loss of energy. When a gas is cooled, its particles move more slowly, and those that are slow enough to linger in each other's vicinity tend to coalesce because a force of attraction overcomes their lowered kinetic energy—i.e., energy of motion. Each particle, when it joins the liquid state with others, gives up a measure of heat called the latent heat of liquefaction, but each continues to move at the same speed within the liquid so long as the temperature remains at the condensation point. Warming up a liquid, by contrast, provides constituent particles with heat of evaporation, which enables them to escape each other and form the vapour of the liquid—namely, the gaseous state.

**gas, natural**: see natural gas.

**gas, perfect** (physics): see perfect gas.

**gas burner**, heating device in which natural gas is used for fuel. Gas may be supplied to the burner prior to combustion at a pressure sufficient to induce a supply of air to mix with it; the mixture passes through several long narrow openings or a nozzle to mix with additional air in the combustion chamber. Metal surfaces supply the means of heat transfer to circulating water or air.

**gas chamber**, method of executing condemned prisoners by lethal gas. It was first used in the U.S. state of Nevada in 1924 in an effort to provide a more humane form of capital punishment. The prisoner is strapped in a chair in a sealed chamber in which poisonous fumes, such as cyanide, are released. If the prisoner breathes deeply, death is almost instantaneous and painless. By the second half of the 20th century, 11 U.S. states had adopted the gas chamber as the method of execution.

During the Holocaust (q.v.) in Nazi Germany during World War II, gas chambers were employed for the purpose of killing Jews and other unwanted minorities. They were established at concentration camps and usually disguised as bathhouses. Men, women, and children were herded naked into the chambers after being told that they were going to take showers. The doors were closed, and poison gas was injected.

**gas chromatography**, in analytical chemistry, technique for separating chemical substances in which the sample is carried by a moving gas stream through a tube packed with a finely divided solid that may be coated with a film of a liquid. Because of its simplicity, sensitivity, and effectiveness in separating components of mixtures, gas chromatography is one of the most important tools in chemistry. It is widely used for quantitative and qualitative analysis of mixtures, for the purification of compounds, and for the determination of such thermochemical constants as heats of solution and vaporization, vapour pressure, and activity coefficients. Gas chromatography is also used to monitor industrial processes automatically: gas streams are analyzed periodically, and manual or automatic responses are made to counteract undesirable variations. Many routine analyses are performed rapidly in medical and other fields. For example, by the use of only 0.1 cubic centimetre (0.003 ounce) of blood, it is possible to determine

the percentages of dissolved oxygen, nitrogen, carbon dioxide, and carbon monoxide. Gas chromatography is also useful in the analysis of air pollutants, alcohol in blood, essential oils, and food products.

The method consists of, first, introducing the test mixture or sample into a stream of an inert gas, commonly helium or argon, that acts as carrier. Liquid samples are vaporized before injection into the carrier stream. The gas stream is passed through the packed column, through which the components of the sample move at velocities that are influenced by the degree of interaction of each constituent with the stationary nonvolatile phase. The substances having the greater interaction with the stationary phase are retarded to a greater extent and consequently separate from those with smaller interaction. As each component leaves the column with the carrier, it passes through a detector and then either goes to a fraction collector or is discarded.

**Gas Hills**, district rich in uranium deposits, east-southeast of Riverton, central Wyoming, U.S. Uranium was first discovered there by Neil and Maxine McNeice in 1953 on a knoll, now called Discovery Hill, and since then the area has been the object of intense mineral exploration. The uranium-rich soil is scraped up by huge earth movers to form some of the world's largest open pits and pit well mines. The area's uranium mills crush the ores; uranium salts (leached out by sulfuric acid) are refined and pressed into yellow cakes of crude uranium compound for shipping.

**gas mask**, breathing device designed to protect the wearer against harmful substances in the air. The typical gas mask consists of a tight-fitting facepiece that contains filters, an exhalation valve, and transparent eyepieces. It is held to the face by straps and can be worn in association with a protective hood. The filter elements in the cheeks of the mask remove contaminants from the air that is drawn through the mask by the wearer's inhaling. The filters, which can be replaced, clean the air but do not add oxygen to it (some masks are connected by a hose to a separate tank of oxygen). The most common filters employ fibre screens (to strain out finely divided solid particles) and chemical compounds such as charcoal (to capture or chemically alter poisonous gases in the air). Charcoal absorbs and holds a fairly large volume of poisonous gases.

Gas masks are widely used by the world's armed forces. Although it is possible to design filtering devices that will neutralize almost any specific toxic substance in the air, it is impossible to combine in one mask protection against all toxic substances. Military gas masks are accordingly constructed with a view to counteracting those chemicals that are thought most likely to be used in wartime. Gas masks are effective only against those chemical-warfare agents that are dispersed as true gases and are injurious when breathed. Agents such as mustard gas that are dispersed in liquid form and attack the body through the skin surface necessitate the use of special protective clothing in addition to gas masks.

**gas meter**, device for measuring the quantity or rate of flow of a gas. Types of gas meters (by operating principles) include displacement, velocity, head, thermal, acoustic, and tracer.

An example of the displacement principle is the bellows-and-diaphragm gas meter (shown in the diagram). This type is widely used in commercial and domestic gas service to measure the quantity of gas delivered to a user. Bellows gas meters measure the quantity of gas passing through them by filling and emptying, in a regular sequence, one or more in-

ternal chambers of known capacity. Counting the times each chamber is filled and emptied gives the volume of gas delivered.

In velocity-type gas meters the gas flow moves impeller blades on a rotor. Rotation of the rotor is geared to a dial mechanism that records gas volume delivered. In the velocity

Bellows-and-diaphragm gas meter  
By courtesy of Rockwell Manufacturing Company

vortex meter the rotor is mounted in an offset chamber in a short section of the flow pipe. Only a portion of the total gas flow is fed into this chamber, and total quantity measurements are based on recorded rotor movement. Velocity gas meters also include anemometer-type meters in which rotating cups or vanes either power a small generator or drive a series of recording registers.

Head-type gas meters measure quantity of gas per unit time. The measurement is based on a deliberately produced pressure drop, or head, between two nearby points in a tube in the meter. This pressure differential can be converted to a flow rate. Devices used to produce the pressure head include orifice plates, venturi tubes, flow nozzles, and pitot tubes.

In thermal-type gas meters a heater (such as an electrical heating coil) is placed in the gas stream, and thermometers are installed on its upstream and downstream sides. Gas flow is measured in relation to either the temperature rise of the gas stream or the amount of electrical energy that is necessary to keep the heater at a constant temperature.

Acoustic gas meters measure the rate of gas flow by comparing the frequency shifts of two initially identical signals (one sent upstream, the other downstream) after they are reflected.

A tracer-type gas meter measures flow rate by timing the passage of an injected radioactive material between two fixed detectors.

**gas plant**, also called DITTANY, BURNING BUSH, or FRAXINELLA (*Dictamnus albus*), or-

Gas plant (*Dictamnus albus*)  
A. J. Huxley—EB Inc

namental, gland-covered perennial herb, of the rue family (Rutaceae), native to Eurasia. The flowers (white or pink) and the leaves give off a strong aromatic vapour which can be ignited, hence the names gas plant and burning bush.

**gas reservoir**, in geology, naturally occurring storage area, characteristically a folded rock formation such as an anticline, that traps and holds natural gas. The reservoir rock must be permeable and porous to contain the gas, and it has to be capped by impervious rock in order to form an effective seal that prevents the gas from escaping upward or laterally. Typical reservoir rocks are sedimentary in origin and include sands, sandstones, arkoses, and fissured limestones and dolomites. The natural gas migrates into these from the compact and less permeable source rock (e.g., clays and fine-grained limestones) because of the pressure difference between the source rocks, which are compressed by the weight of overlying rocks, and the reservoir rocks, which are at lower pressures. Recovery from the reservoir is effected principally by the natural expansion of the gas.

In the United States and certain other countries, artificial gas reservoirs are being created from depleted oil and gas fields, particularly near salt domes and in sedimentary basins, to store gas during periods of low consumption for later use.

**Gascogne, Golfe de:** see Biscay, Bay of.

**Gascoigne, George** (b. c. 1525, Cardington, Bedfordshire, Eng.—d. Oct. 7, 1577, Bernack, near Stamford, Lincolnshire), English poet and a major literary innovator.

Gascoigne attended the University of Cambridge, studied law at Gray's Inn in 1555, and thereafter pursued careers as a politician,

George Gascoigne, woodcut, 1576

By courtesy of the trustees of the British Museum, photograph, J. R. Freeman & Co. Ltd.

country gentleman, courtier, soldier of fortune, and man of letters, all with moderate distinction. He was a member of Parliament (1557–59). Because of his extravagance and debts, he gained a reputation for disorderly living. He served with English troops in the Low Countries, ending his military career as a repatriated prisoner of war. In 1575 he helped to arrange the celebrated entertainments provided for Queen Elizabeth I at Kenilworth and Woodstocke and in 1576 went to Holland as an agent in the royal service. Among his friends were many leading poets, notably George Whetstone, George Turberville, and Edmund Spenser.

Gascoigne was a skilled literary craftsman, memorable for versatility and vividness of expression and for his treatment of events based on his own experience. His chief importance, however, is as a pioneer of the English Renaissance who had a remarkable aptitude for domesticating foreign literary genres. He foreshadowed the English sonnet sequences with groups of linked sonnets in his first published

work, *A Hundreth sundrie Flowres* (1573), a collection of verse and prose. In *The Posies of George Gascoigne* (1575), an authorized revision of the earlier work, which had been published anonymously, he included also "Certayne notes of Instruction," the first treatise on prosody in English. In *The Steele Glas* (1576), one of the earliest formal satires in English, he wrote the first original nondramatic English blank verse. In two amatory poems, the autobiographical "Dan Bartholomew of Bathe" (published in *A Hundreth sundrie Flowres*) and *The Complaite of Phylomene* (1576), Gascoigne developed Ovidian verse narrative, the form used by William Shakespeare in *Venus and Adonis* and *The Rape of Lucrece*.

"The Adventures of Master F.J.," published in *A Hundreth sundrie Flowres*, was the first original prose narrative of the English Renaissance. Another prose work, *The Spoyle of Antwerpe* (1576), is an early example of war journalism, characterized by objective and graphic reporting.

Gascoigne's *Jocasta* (performed in 1566) constituted the first Greek tragedy to be presented on the English stage. Translated into blank verse, with the collaboration of Francis Kinwelmersh, from Lodovico Dolce's *Giocasta*, the work derives ultimately from Euripides' *Phoenissae*. In comedy, Gascoigne's *Supposes* (1566?), a prose translation and adaptation of Ludovico Ariosto's *I Suppositi*, was the first prose comedy to be translated from Italian into English. A dramatically effective work, it provided the subplot for Shakespeare's *The Taming of the Shrew*. A third play, *The Glasse of Government* (1575), is a didactic drama on the Prodigal Son theme. It rounds out the picture of Gascoigne as a typical literary man of the early Renaissance.

**Gascony**, French GASCOGNE, historical and cultural region encompassing the southwestern French *départements* of Landes, Gers, and Hautes-Pyrénées and parts of Pyrénées-Atlantiques, Lot-et-Garonne, Tarn-et-Garonne, Haute-Garonne, and Ariège and coextensive with the historical region of Gascony.

During ancient Roman rule in Gaul, the area, which was ethnically more Iberian than Celtic, was detached from Aquitania to form the separate province of Novempopulana. Taken from the Visigoths by the Franks after the Battle of Vouillé (507), the region was overrun from 561 by the Basques, or Vascones; in 602 the Frankish kings recognized Vasconia, or Gascony, as a duchy under the national leader Genialis. In the latter half of the 7th century, the Gascon duke Loup extended his power over adjacent areas, and by the latter half of the 10th century his successors controlled all of Gascony as well as Bordeaux, Bazadais, and Agenais (now Agen).

The duchy of Gascony, c. 1035

From W. Shepherd, *Historical Atlas*, Harper & Row, Publishers (Barnes & Noble Books), New York, revision Copyright © 1964 by Barnes & Noble, Inc.

In 1032 a war of succession broke out, and Gascony was eventually won in 1052 by Guy-Geoffrey (from 1058 William VIII, duke of Aquitaine). But in the meantime, effective power within the duchy had devolved on the greater counts and viscounts (such as those of Armagnac and Lomagne), who were to dominate Gascony for centuries. In the 12th century the ducal title passed with the Aquitanian inheritance to the Plantagenet kings of England. Throughout the years of intermittent warfare between England and France, up to the definitive French reconquest at the end of the Hundred Years' War, Gascony remained the kernel of English royal power in southwestern France. Gascony was merged with Guyenne in the *gouvernement* of Guyenne-et-Gasconne during the ancien régime.

The region consists of the northern foothills of the Pyrenees mountain chain and extends from the Basque Country along the France-Spain border in the extreme southwestern corner of France eastward some 150 miles (240 km) to the vicinity of Toulouse. The traditional farmstead of the Basque Country is built of a mixture of clay and straw and covered with wood shingles; above the portal is a placard that features the date of construction or the name of the proprietor. The patriarch of the Basque family is the *etcheke jaun*; his primary task is to preserve the patrimony intact, and the custom of undivided inheritance has resulted in the emigration of disinherited sons and daughters. Pastures in the Basque Country are often collectively owned.

The Basques, who were not converted to Christianity until the 10th century, are predominantly Roman Catholic. The Basque language continues to be spoken by approximately one-fifth of the Basques living in France. The Gascon dialect is a variant of Occitan and is distinguished by strong Basque influences. French was adopted as the literary language in the 16th century; numerous folkloric poems in the Gascon dialect have been preserved. The stereotyped Gascon of French popular literature is impetuous and hotheaded (e.g., the elder Alexandre Dumas's character d'Artagnan and Edmond Rostand's Cyrano de Bergerac).

**Gascoyne, David (Emery)** (b. Oct. 10, 1916, Harrow, Middlesex, Eng.—d. Nov. 25, 2001, Newport, Isle of Wight), English poet deeply influenced by the French Surrealist movement of the 1930s.

Gascoyne's first book of poems, *Roman Balcony*, appeared in 1932, and his only novel, *Opening Day*, the next year. The royalty advance for *Opening Day* enabled him to visit Paris, which encouraged a passionate interest in Surrealism. His important introductory work, *A Short Survey of Surrealism* (1935), and his verses *Man's Life Is This Meat* (1936) were milestones of the movement in England. *Poems, 1937-42* (1943) marked the beginning of his religious verse and contains his noted good-bye to the '30s—"Farewell Chorus." *Night Thoughts*, a long, semidramatic poem, was broadcast in 1955 and published the next year.

Gascoyne's early poetry bears the Surrealist impress boldly, and, through his translations of works by Salvador Dalí and André Breton and his critical writings, he did much to make the movement known in Britain. Gascoyne's *Collected Poems 1988* (1988) is a revised and enlarged version, with autobiographical introduction, of a volume first published in 1965. His *Collected Verse Translations*, chiefly from the French, was released in 1970. *Paris Journal, 1937-1939* (1978) and *Journal 1936-37* (1980), jointly published as *Collected Journals, 1936-42* in 1991, record the political and artistic movements of the late 1930s.

**Gascoyne-Cecil, James Edward Hubert:** see Salisbury, James Edward Hubert Gascoyne-Cecil, 4th Marquess of.

**Gascoyne-Cecil, (Edgar Algernon) Robert:** see Cecil (of Chelwood), (Edgar Algernon) Robert Gascoyne-Cecil, 1st Viscount.

**Gascoyne-Cecil, Robert:** see Salisbury, Robert Arthur Talbot Gascoyne-Cecil, 3rd Marquess of.

**Gascoyne River**, ephemeral river of west-central Western Australia. It rises in the north-eastern Robinson Ranges west of the Gibson Desert, flows generally westward for 475 miles (760 km) through gold-mining and sheep-raising country, and empties into the Indian Ocean at Carnarvon on Shark Bay. It is joined by the 225-mile- (360-km-) long Lyons River about 100 miles (160 km) above its mouth. Although frequently dry, it is the chief source of water for Carnarvon. Bananas and vegetables are grown along its lower course on land irrigated from wells dug in the riverbed. The wool-producing region along its upper course is known as the Gascoyne. The river was first sighted in 1839 by Captain George Grey, who became governor of South Australia (1841-45), and was named for his friend, one Captain Gascoyne of the Royal Navy.

**gases, kinetic theory of:** see kinetic theory of gases.

**Gash River**, Arabic NAHR AL-QĀSH, river rising in southern Eritrea, near Asmera. After flowing southward, it turns west and forms the border between Eritrea (north) and Ethiopia (south) along its middle course. It then continues into northeastern Sudan to lose itself in the desert. In time of flood it reaches the 'Atbarah River. It is known as the March on its upper course and is used for irrigation around Teseney, in Eritrea, and around Kasalā, in The Sudan. The Gash River has a total course of about 300 miles (480 km).

**Gaskell, Elizabeth Cleghorn, née STEVENSON** (b. Sept. 29, 1810, Chelsea, London, Eng.—d. Nov. 12, 1865, near Alton, Hampshire), English novelist, short-story writer, and first biographer of Charlotte Brontë.

Elizabeth Gaskell, chalk drawing by George Richmond, 1851; in the National Portrait Gallery, London  
By courtesy of the National Portrait Gallery, London

She was a daughter of a Unitarian minister. When her mother died, she was brought up by a maternal aunt in the Cheshire village of Knutsford in a kindly atmosphere of rural gentility that was already old-fashioned at the time. In 1832 she married William Gaskell, a Unitarian minister, and settled in the overcrowded, problem-ridden industrial city of Manchester, which remained her home for the rest of her life. Domestic life—the Gaskells had six children, of whom four daughters lived to adulthood—and the social and charitable obligations of a minister's wife claimed her time but not all her thoughts. She did not begin her literary career until middle life, when the death of her only son intensified her

sense of community with the poor and her desire to "give utterance" to their "agony." Her first novel, *Mary Barton*, reflects the temper of Manchester in the late 1830s. It is the story of a working-class family in which the father, John Barton, lapses into bitter class hatred during a cyclic depression and carries out a retaliatory murder at the behest of his trade union. Its timely appearance in the revolutionary year of 1848 brought the novel immediate success, and it won the praise of Charles Dickens and Thomas Carlyle. Dickens invited her to contribute to his magazine, *Household Words*, where her next major work, *Cranford* (1853), appeared. This social history of a gentler era, which describes, without sentimentalizing or satirizing, her girlhood village of Knutsford and the efforts of its shabby-genteel inhabitants to keep up appearances, has remained her most popular work.

The conflict between Mrs. Gaskell's sympathetic understanding and the strictures of Victorian morality resulted in a mixed reception for her next social novel, *Ruth* (1853). It offered an alternative to the seduced girl's traditional progress to prostitution and an early grave.

Among the many friends attracted by Mrs. Gaskell was Charlotte Brontë, who died in 1855 and whose biography Charlotte's father, Patrick Brontë, urged her to write. The *Life of Charlotte Brontë* (1857), written with warmhearted admiration, disposed of a mass of firsthand material with enforced narrative skill. It is at once a work of art and a well-documented interpretation of its subject.

Among her later works, *Sylvia's Lovers* (1863), dealing with the impact of the Napoleonic Wars upon simple people, is notable. Her last and longest work, *Wives and Daughters* (1864–66), concerning the interlocking fortunes of two or three country families, is considered by many her finest. It was left unfinished at her death.

**gasoline**, also spelled GASOLINE, also called GAS, or PETROL, mixture of volatile, flammable liquid hydrocarbons derived from petroleum and used as fuel for internal-combustion engines. It is also used as a solvent for oils and fats. Originally a by-product of the petroleum industry (kerosene being the principal product), gasoline became the preferred automobile fuel because of its high energy of combustion and capacity to mix readily with air in a carburetor.

Gasoline was at first produced by distillation, simply separating the volatile, more valuable fractions of crude petroleum. Later processes, designed to raise the yield of gasoline from crude oil, split large molecules into smaller ones by processes known as cracking. Thermal cracking, employing heat and high pressures, was introduced in 1913 but was replaced after 1937 by catalytic cracking, the application of catalysts that facilitate chemical reactions producing more gasoline. Other methods used to improve the quality of gasoline and increase its supply include polymerization, converting gaseous olefins, such as propylene and butylene, into larger molecules in the gasoline range; alkylation, a process combining an olefin and a paraffin such as isobutane; isomerization, the conversion of straight-chain hydrocarbons to branched-chain hydrocarbons; and reforming, using either heat or a catalyst to rearrange the molecular structure.

Gasoline is a complex mixture of hundreds of different hydrocarbons. Most are saturated and contain 4 to 12 carbon atoms per molecule. Gasoline used in automobiles boils mainly between 30° and 200° C (85° and 390° F), the blend being adjusted to altitude and season. Aviation gasoline contains smaller proportions of both the less-volatile

and more-volatile components than automobile gasoline.

The antiknock characteristics of a gasoline—its ability to resist knocking, which indicates that the combustion of fuel vapour in the cylinder is taking place too rapidly for efficiency—is expressed in octane number. The addition of tetraethyllead to retard the combustion was initiated in the 1930s but was discontinued in the 1980s because of the toxicity of the lead compounds discharged in the combustion products. Other additives to gasoline often include detergents to reduce the buildup of engine deposits, anti-icing agents to prevent stalling caused by carburetor icing, and antioxidants (oxidation inhibitors) used to reduce "gum" formation.

In the late 20th century the rising price of petroleum (and hence of gasoline) in many countries led to the increasing use of gasohol, which is a mixture of 90 percent unleaded gasoline and 10 percent ethanol (ethyl alcohol). Gasohol burns well in gasoline engines and is a desirable alternative fuel for certain applications because of the renewability of ethanol, which can be produced from grains, potatoes, and certain other plant matter. *See also* petroleum.

**gasoline engine**, any of a class of internal-combustion engines that generate power by burning a volatile liquid fuel with ignition initiated by an electric spark.

A brief treatment of gasoline engines follows. For full treatment, *see* MACROPAEDIA: Energy Conversion.

The gasoline engine is the most widely used form of internal-combustion engine. The majority of automobiles are powered by gasoline engines, as are many motorcycles and small trucks and tractors. A few large systems capable of up to 35,000 horsepower are employed as aircraft engines, while small, lightweight models provide motive power for such machines as lawnmowers and snowblowers.

*Principles of operation.* Although gasoline engines vary significantly in size, weight per unit of power generated, and arrangement of components, they all are basically similar. The principal type of gasoline engine is the reciprocating-piston engine. Such engines can be subdivided into two groups according to whether the operating cycle is completed in two or in four strokes of the piston. In the four-stroke cycle basic to automobile engines, the piston first descends on the intake stroke, during which the inlet valve is held open. Fresh charge (air mixed with gasoline vapour) is drawn into the cylinder by the partial vacuum created by the descent of the piston. The piston then ascends on the compression stroke with both the inlet and exhaust valves closed, and the charge is ignited by an electric spark as the end of the stroke is approached. The power stroke follows, with both valves still closed and gas pressure acting on the piston crown because of the expansion of the burned charge. The exhaust stroke then completes the cycle, with the ascending piston forcing the spent products of combustion past the exhaust valve, now held open by the valve train. The cycle then repeats itself. Each cycle thus requires four strokes of the piston—intake, compression, power (expansion), and exhaust—and two revolutions of the crankshaft.

In a two-stroke cycle the compression and power strokes of the four-stroke cycle are carried out without the inlet and exhaust strokes. In short, the two-stroke cycle is completed in one upstroke and one downstroke of the piston and a single revolution of the crankshaft. Because of this, the size, weight, and cost of the engine per horsepower are reduced. Accordingly, two-stroke-cycle engines are used in a variety of motorcycles and smaller machines (*e.g.*, lawnmowers and power rakes).

A second major type of gasoline engine is the rotary engine. Among the different versions

that have been introduced over the years, the rotary-piston engine designed by Felix Wankel, a German engineer, has proved to be the most practical, though the Tri-Dyne engine (a British design) is thought by some to be superior in certain respects. The Wankel engine is structurally different from the conventional reciprocating-piston engine. The Wankel has a rotor shaped like an equilateral triangle instead of pistons that move up and down in cylinders. The rotor turns in a closed chamber, and the three apexes of the rotor maintain a continuous sliding contact with the curved inner surface of the casing. The curve-sided rotor forms three crescent-shaped chambers between its sides and the wall of the casing. The volume of each chamber varies with the rotor motion. Maximum volume is attained in a chamber when the side of the rotor forming it is parallel with the major diameter. Pockets recessed in the flanks of the rotor control the shape of the combustion chamber and establish the compression ratio of the engine. In turning about its central axis, the rotor has to follow a circular orbit about the geometric centre of the casing. It is guided by fitting its central bore to an eccentric formed on the output shaft that passes through the centre of the stationary pinion. This eccentric also harnesses the rotor to the shaft so that torque is applied when gas pressure is exerted against the rotor flanks as the fuel-and-air mixture burns. A 3-to-1 gear ratio causes the output shaft to turn three times as fast as the rotor turns about the eccentric. Each quarter turn of the rotor completes an expansion or a compression, thereby permitting intake, compression, expansion, and exhaust during one turn of the rotor.

The Wankel engine is lighter and more compact than the conventional reciprocating-piston type, and it is less expensive to manufacture because of its mechanical simplicity. Other advantages include quiet and vibrationless operation and much higher operating speeds, primarily due to the absence of inertial forces from reciprocating parts. The Wankel engine has been employed for automotive and marine applications on a limited scale.

*Development of the gasoline engine.* In 1862 Alphonse Beau de Rochas, a French engineer, established the principle of the four-stroke cycle. In 1876 the German engineer Nikolaus Otto applied Beau de Rochas's principle in constructing what is commonly considered a prototype of the modern automobile engine. Sir Dougald Clerk developed the two-stroke cycle in 1878. A simplified, more efficient version of this operation was introduced in 1891 by Joseph Day. The rotary gasoline engine was not developed until the 20th century.

**Gasparri, Pietro** (b. May 5, 1852, Capovalazza de Ussita, Papal States [Italy]—d. Nov. 18, 1934, Rome, Italy), Italian cardinal who, by appointment of Pope St. Pius X, in 1904 directed the new Code of Canon Law, a systematic arrangement of ecclesiastical law now practiced by the Roman Catholic church.

Ordained in 1877, Gasparri was professor of canon law at the Catholic Institute, Paris (1880–98). In 1907 he was made cardinal, and in 1914 Pope Benedict XV appointed him secretary of state. His new code (*Codex Juris Canonici*) was promulgated in 1917. He was retained by Pope Pius XI and in 1926 began the secret negotiations with Prime Minister Benito Mussolini of Italy that resulted in the Lateran Treaty (1929), an agreement securing papal independence from Italy.

**Gaspé**, city, Gaspésie region, eastern Quebec province, Canada. It lies at the mouth of the York River, overlooking Gaspé Bay. The city's name derives either from the navigator Gaspar Corte-Real, who came there about 1500, or from the Indian *gespeg*, meaning "end of the world." Its site was visited in 1534 by the explorer Jacques Cartier, who set up a

cross there, claiming the Canadian mainland for the king of France. The fishing port that later developed survived a disastrous attack by the British under General James Wolfe in 1758. While fishing is still important (it is the site of a provincial fish hatchery), lumbering, tourism, and, more recently, copper and oil production have become the main industries. Gaspé is an eastern terminus of the Canadian National Railway and the seat of a Roman Catholic diocese. Pop. (1991) 16,402.

**Gaspé, Philippe Aubert de** (b. Oct. 30, 1786, Quebec, Que. [now in Canada]—d. Jan. 29, 1871, Quebec), author of the first important French-Canadian novel.

Gaspé, engraving, 1871

By courtesy of the Public Archives of Canada

The son of a distinguished Quebec family, Gaspé inherited the family estate on the St. Lawrence River. He received a classical education in Quebec, studied law there, and later became sheriff. Bankruptcy, for which he spent over three years in debtors' prison, forced his withdrawal from public life in his 49s into a quiet life of reading and meditation.

When he was 76 years old, inspired by a rebirth of Canadian nationalism in the mid-19th century, Gaspé wrote *Les Anciens Canadiens* (1863; *The Canadians of Old*). A French-Canadian classic, it is a romantic historical novel set in Canada at the time of the British conquest (1760). Its idealization of the "good old days," the farmer's loyalty to the soil, and distrust of English Canada influenced the Canadian regionalist school of literature that flourished into the 1930s.

**Gaspé Peninsula**, French PÉNINSULE DE LA GASPÉSIE, English GASPESIA, peninsula in eastern Quebec province, Canada. The peninsula extends east-northeastward for 150 miles (240 km) from the Matapédia River into the Gulf of St. Lawrence. It is situated between the St. Lawrence River (north) and Chaleur Bay and New Brunswick (south). The well-forested Monts Chic-Choc (Shickshock Mountains), which are an extension of the Appalachians, parallel the St. Lawrence in the north-central

portion and rise to Mount Jacques Cartier (4,160 feet [1,268 m]). A number of rivers drain the peninsula, including the Cascapédia, Saint-Jean, York, Grande, and du Grand Pabos. The chief settlements are along the coast: Matane, Gaspé, Percé, Chandler, and New-Carlisle.

Much of the region is within conservation areas, including Gaspesian Provincial Park. A highway encircling the peninsula affords views of the rugged and picturesque coastal and mountain scenery. Forillon, a national park occupying 93 square miles (240 square km), is at the northeastern tip of the peninsula. Both sporting and local interests benefit from the excellent hunting and fishing; the peninsula is drained by several outstanding salmon rivers. Lumbering is also a main economic activity; and there is some mining of copper, lead, and zinc and the production of pulp for paper-making.

**Gaspee, Burning of the** (June 10, 1772), in U.S. colonial history, act of open civil defiance of British authority when Rhode Islanders boarded and sank the revenue cutter *Gaspee* in Narragansett Bay. Headed by a leading merchant, John Brown, eight boatloads of armed, reputable citizens overpowered the crew of the *Gaspee*, which had run aground in pursuit of a smuggling vessel, disabled her commander, and set fire to the ship. Despite concerted British efforts to bring the culprits to justice, the raiding party was never punished.

**gaspereau** (fish): see alewife.

**Gasperi, Alcide de:** see De Gasperi, Alcide.

**Gaspesian Provincial Park**, French PARC PROVINCIAL DE LA GASPÉSIE, park in eastern Quebec province, Canada. The park occupies 500 square miles (1,295 square km) on the Gaspé Peninsula, near the mouth of the St. Lawrence River. It was established in 1937 to protect the fast-diminishing herds of caribou as well as to preserve the natural beauty of the region, which is heavily wooded with many lakes and streams. Extending from east to west are the Monts Chic-Choc (Shickshock Mountains), with some rare species of Alpine flora; Mount Jacques Cartier (4,160 feet [1,268 m]) is the highest peak. The park's domain includes Port-Daniel (southeast), the Saint-Jean-Rivière district (east), the Lapetite-Cascapédia-Rivière (south), and the Matane River country (west)—all of which are well known for salmon fishing.

**Gasprinski, Ismail**, also called ISMAIL GASPIRALI (b. 1851, Avci, near Bakhchisaray, Crimea, Russian Empire [now in Ukraine]—d. Sept. 11, 1914, Bakhchisaray), Turkish journalist and writer who was an advocate of pan-Islamic unity and whose writings significantly contributed to the growth of cultural identity within the Turkic community of Russia.

An ethnic Turk, Gasprinski was educated at

a Moscow military school. In 1871 he traveled to Vienna and then to Paris, where he came in contact with liberal Ottoman refugees. Back in his native Crimea three years later, he was appointed mayor of Bakhchisaray (1878), and in the following year, upon being denied permission to publish a newspaper, he became a correspondent of the Russian-language newspaper *Tavrida*, for which he wrote a series of articles on the cultural problems of the predominantly Turkic Muslims in Russia. Finally (1883) he was permitted to publish his own bilingual Russian and Turkish paper, *Tercümân* ("The Interpreter"), which, as a medium for the transmission of Western ideas and for the promotion of pan-Islamic and pan-Turkic unity, became the most influential Turkish newspaper of Russia.

Gasprinski devoted all his time to *Tercümân*, on behalf of which he traveled extensively in the Middle East as well as to the various Turkic communities of Russia. He was also an active supporter of what he called the *usul jadid* ("new method") in education, which advocated the phonetic teaching of Arabic and curriculum reforms that included such subjects as mathematics, history, and geography.

**Gasquet, Francis Aidan**, in full FRANCIS NEIL AIDAN GASQUET (b. Oct. 5, 1846, London, Eng.—d. April 5, 1929, Rome, Italy), English Roman Catholic historian, a cardinal from 1914, and prefect of the Vatican archives from 1917.

Educated at Downside School (Somerset), Gasquet entered the Benedictine monastery there and was prior from 1878 to 1885. From 1888 onward he published works on monastic history, including *Henry VIII and the English Monasteries* (1888–89), which has considerable value but is regarded by some as biased and occasionally inaccurate. Other works include *A History of the Church in England*, 2 vol. (1897), and *Parish Life in Medieval England* (1909).

*A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume*

**Gass, William H.**, in full WILLIAM HOWARD GASS (b. July 30, 1924, Fargo, N.D., U.S.), American writer noted for his experimentation with stylistic devices.

Gass called his fiction works "experimental constructions," and each of his books contains stylistic innovations. His first novel, *Omenseiter's Luck* (1966), is about a man whose purity and good fortune are tainted when he is maliciously and falsely connected to a mysterious death. By piecing together various viewpoints, Gass creates levels of insight into character and setting; he does this, however, without the use of quotation marks to distinguish speakers. His novella *Willie Masters' Lonesome Wife* (1968)—a woman's reflections on her life and on language—makes use of typographical and other visual devices. Gass's lush, acrobatic style has been criticized by some as being achieved at the expense of characterization, plot, and such conventions as punctuation.

Gass's other work includes *In the Heart of the Heart of the Country* (1968), short stories; *Fiction and the Figures of Life* (1970), collected critical essays; *On Being Blue* (1976), imaginative interpretations of the colour blue; and *The World Within the Word* (1978), another collection of critical essays. Gass taught philosophy at the College of Wooster (Wooster, Ohio), Purdue University (West Lafayette, Ind.), and Washington University (St. Louis, Mo.).

**Gassendi, Pierre**, Gassendi also spelled GASSEND (b. Jan. 22, 1592, Champstecier,

Petit Cap, a fishing village on the Gaspé Peninsula coast, Que.

Ed Cooper—Shostal

Provence, Fr.—d. Oct. 24, 1655, Paris), French scientist, mathematician, and philosopher who revived Epicureanism as a substitute for Aristotelianism, attempting in the process to reconcile mechanistic Atomism with Christian belief in immortality, free will, an infinite God, and creation.

Gassendi received a doctorate in theology at Avignon (c. 1614) and was ordained a priest the following year. Persuaded by the mathematician-theologian Marin Mersenne to abandon mathematical and theological pursuits in favour of philosophy, he turned to Epicureanism. In *Syntagma Philosophicum*, published posthumously (1658; "Philosophical Treatise") among his collected works, he followed the Epicurean triple division of philosophy. In part one (logic) he rejected the innate ideas of Descartes and emphasized the inductive method and the senses as primary sources of knowledge; however, as a mathematician, he also accepted deductive reasoning. In part two (physics) he defended a mechanistic explanation of nature and sensation. His proof for a rational and immortal soul derived from man's awareness of moral values, universal ideas, and the power of reflective thought. Gassendi saw in the harmony of nature proof for the existence of God. In part three (ethics) he viewed happiness (peace of soul and absence of bodily pain) as the end of man, only imperfectly attainable in this life.

Gassendi's philosophical writings include several works on the life, pleasures, and ethics of Epicurus and rather lengthy objections (1641) to Descartes's *Meditations*. His *Disquisitiones Metaphysicae* (1644; "Disquisition on Metaphysics") was a consequence of Descartes's reply to his criticism.

Gassendi was the first to observe a planetary transit, that of Mercury in 1631, predicted by Kepler. His publications on science were considerable, but his greatest influence was through philosophical Atomism.

**Gasser, Herbert Spencer** (b. July 5, 1888, Plattville, Wis., U.S.—d. May 11, 1963, New York City), American physiologist, corecipient (with Joseph Erlanger) of the Nobel Prize for Physiology or Medicine in 1944 for fundamental discoveries concerning the functions of different kinds of nerve fibres.

At Washington University, St. Louis, Mo. (1916–31), where he was professor of pharmacology, Gasser collaborated with Erlanger in studying the barely detectable electrical impulses carried by isolated mammalian nerve fibres. By 1924 they had succeeded in adapting the oscillograph to physiological research, enabling them to visualize amplified nerve impulses on a fluorescent screen. Using this device, they demonstrated that different nerve fibres exist for the transmission of specific kinds of impulses, such as those of pain, cold, or heat. Their work also made it possible to construct improved recording machines to diagnose brain and nervous disorders and to ascertain the success of treatments for these diseases.

In 1931 Gasser was appointed professor of physiology at Cornell University, Ithaca, N.Y., and four years later he succeeded Simon Flexner as director of the Rockefeller Institute, New York City (1935–53).

**Gastein** (Austria): see Badgastein.

**Gastein, Convention of**, also called CONVENTION OF BADGASTEIN, agreement between Austria and Prussia reached on Aug. 20, 1865, after their seizure of the duchies of Schleswig and Holstein from Denmark in 1864; it temporarily postponed the final struggle between them for hegemony over Germany. The pact provided that both the emperor of Austria and the king of Prussia were to be sovereign over

the duchies, Prussia administering Schleswig and Austria administering Holstein (which was sandwiched between Schleswig to the north and Prussian territory to the south). Both duchies were to be admitted to the Zollverein (German Customs Union), headed by Prussia, though Austria was not a member.

This joint administration led to disputes between the two powers that ended with Austria's defeat and exclusion from Germany (1866).

**Gastein Valley**, German GASTEINERTAL, side valley of the Salzach River, in *Bundesland* (federal state) Salzburg, west-central Austria. Lying along the north slope of the Hohe Tauern Mountains and traversed by the Gasteiner River, it is a popular scenic area centred on the resorts of Badgastein (q.v.) and Bad Hofgastein.

**Gasteromycetes**, name often given to a group of fungi of the class Basidiomycetes (division Mycota) consisting of more than 700 species. Their spores, called basidiospores, are borne within a variety of fruiting bodies (basidiocarps) that are often spherical or egg-shaped and resemble mushrooms. Included among the Gasteromycetes are the bird's nest fungi (*Cru-*

Bird's nest fungi (*Crucibulum vulgare*)

Peter Katsaros

*cibulum* of the order Nidulariales), earthstars (*Gastromyces* species of the order Lycoperdales), puffballs (Lycoperdales), and stinkhorns and other phalloids (Phallales). The basidiospores are not forcibly discharged but are freed after the basidiocarp disintegrates.

**gasterosteiform**, any member of the order Gasterosteiformes, a group of bony, tube-mouthed fishes that contains well-known forms such as the sea horse, pipefish, and stickleback as well as the less familiar snipefish, tubesnout, shrimpfish, and ghost pipefish. Gasterosteiforms are of little economic value to humans except for the popularity of a few species as aquarium fish.

A brief treatment of gasterosteiforms follows. For full treatment, see MACROPAEDIA: Fishes.

Gasterosteiforms range in size from 3 cm (about 1 inch) to 200 cm (80 inches). They typically have soft fin rays, a swim bladder unconnected to the gut, pelvic fins located on the abdomen, and a covering of bony, ganoid plates. They are abundant in the waters of the Northern Hemisphere.

Except for snipefishes, gasterosteiforms inhabit areas of dense aquatic plant growth. Their defensive behaviour generally consists of resting vertically among grasses, sea urchins, corals, and similar structures. This posture serves to camouflage the fish and presents its body spines to any predator. Sea horses use their prehensile tails to grasp vegetation and hold themselves in place; they can also use their swim bladder to rise or settle at different depths. Snipefishes can swim backward or forward equally well.

**Gastfenger, Polykarpus**: see Hoffmann, Heinrich.

**Gaston III**, byname GASTON PHOEBUS, or PHEBUS (b. 1331—d. August 1391), count of Foix from 1343, who made Foix one of

Gaston III giving orders to men, manuscript illumination from *Livre de la Chasse*, 14th century; in the Bibliothèque Nationale, Paris

By courtesy of the Bibliothèque Nationale, Paris

the most influential and powerful domains in France. A handsome man (hence the surname Phoebus), his court in southern France was famous for its luxury. His passion for hunting led him to write the treatise *Livre de la chasse* ("Book of the Hunt"). It was translated into English by Edward of Norwich, 2nd Duke of York, as the bulk of the first English book on hunting, *The Master of Game*.

In 1345, early in the Hundred Years' War (1337–1453), Gaston fought against the English and in 1347 was named special lieutenant general in southern France. Suspected of conspiring with his brother-in-law Charles II the Bad, king of Navarre, against France, he was imprisoned in 1356. When he was released, he went to fight the pagans in Prussia.

In 1358, after his return to France, he saved some members of the royal family as they were besieged in the marketplace of Meaux during the peasant revolt called the Jacquerie. He was forced to depart immediately to combat the Count d'Armagnac in an old family rivalry over the countship of Bigorre. Having defeated him in 1372, Gaston arranged a truce that was sealed by the marriage of his son to one of the daughters of the Count d'Armagnac.

In 1380 Gaston Phoebus was named lieutenant general of Languedoc by Charles V of France but upon the latter's death that same year he lost the position to the Duke de Berry. Enraged, Gaston defeated the duke in combat and then retired to his mountain estates.

Suspecting his only son (also named Gaston) of plotting to poison him, Gaston had the youth put in prison, where he died.

**Gaston DE FRANCE**: see Orléans, Gaston (-Jean-Baptiste), duc d'.

**Gastonia**, city, seat (1909) of Gaston county, south-central North Carolina, U.S., in the central Piedmont Plateau. The site was settled in the late 18th century and named for William Gaston, a congressman and judge. After the establishment of its first cotton mill in 1848, Gastonia became one of the nation's largest textile-manufacturing centres. In 1929 the city was the scene of a sensational strike during which the chief of police was killed. The episode and ensuing murder trials inspired several novels, notably, *Strike!* (1930) by Mary Heaton Vorse and *To Make My Bread* (1932) by Grace Lumpkin. Gaston College at nearby Dallas was founded in 1963, and Belmont Abbey Cathedral and College (1878) is 8 miles (13 km) east. Kings Mountain National Military Park, site of an American Revolutionary War battle, is 20 miles (32 km) southwest. Inc. city, 1877. Pop. (1990) city, 54,732; Charlotte-Gastonia-Rock Hill MSA, 1,162,093.

**gastrectomy**, surgical removal of all or part of the stomach, a procedure that is used to treat peptic ulcers. The operation eliminates the gastric-acid-secreting parietal cells in the

stomach lining and halts the production of the acid-stimulating hormone gastrin, thus removing the cause of the ulcer. Once a common method of treatment for patients with painful ulcers, gastrectomy is now used only as a last resort if the appropriate drugs have failed or if an ulcer is perforated or hemorrhaging.

The most common procedure is antrectomy, which removes the lower half of the stomach (antrum), the chief site of gastrin secretion. The remaining stomach is then reconnected to the first section of the small intestine (duodenum). In a more extensive procedure, subtotal gastrectomy, as much as three-quarters of the stomach is removed, including all of the antrum. The remaining stomach may then be reattached directly to the duodenum or to the jejunum, a more distal part of the intestine beyond the usual site of ulceration.

The incidence of ulcer recurrence after gastrectomy is very low (about 2 percent) when the antrum is completely removed. The most significant drawback to gastrectomy is general malnutrition, caused by decreased appetite and by the stomach's decreased ability to digest food.

**gastric gland**, any of the simple branched tubules in the inner lining of the stomach that secrete gastric juice and protective mucus.

The gastric glands are of three types, distinguished by location and type of secretion. The cardiac gastric glands are located at the very beginning of the stomach; the intermediate, or true, gastric glands in the central stomach areas; and the pyloric glands in the terminal stomach portion. Both the cardiac and pyloric glands secrete mucus, which coats the stomach and protects it from self-digestion by helping to dilute acids and enzymes.

The intermediate gastric glands produce most of the digestive substances secreted by the stomach. These glands are narrow tubules composed of three major cell types: zymogenic, parietal, and mucous neck cells. At the base of the gland are the zymogenic (chief) cells, which are thought to produce the enzymes pepsin and rennin (pepsin digests proteins and rennin curdles milk). Parietal, or oxyntic, cells occur throughout the length of the gland and are responsible for the production of hydrochloric acid, which is necessary to activate the other enzymes. The mucous neck cell's sole purpose is to secrete mucus.

There is usually a small, constant production of gastric juices, but their secretion can be stimulated by numerous means. Tasting, smelling, or thinking of food tends to increase enzyme secretions. Their production is limited while a person is asleep, but production resumes upon awakening. Consumed food provides the tactile stimulation necessary for mucus secretion. Some foods also contain chemicals that activate enzyme production. Psychological states of fear, sadness, or withdrawal tend to reduce gastric secretion, while excitement and aggressiveness increase it.

**Gästrikland**, *landskap* (province), eastern Sweden. It lies along the Gulf of Bothnia, in the administrative *län* (county) of Gävleborg. With a land area of 1,614 square miles (4,181 square km), it is one of the smaller traditional provinces of Sweden. Bounded on the south by the province of Uppland, on the north by that of Hälsingland, and on the west by that of Dalarna, it is transitional in character between central Sweden and the region of Norrland. Inland from its rocky coast, which has many fine beaches, there are numerous lakes and wooded hills. Because of the province's extensive forests, leading industries include lumbering, sawmilling, and the manufacture of wood pulp and paper. Ironworks are also prevalent, having flourished since the Middle Ages; this is especially true of the area around Sandviken, which is famous for its saws. Gävle is the major town. Pop. (2000 est.) 144,619.

**gastritis**, acute or chronic inflammation of the mucosal layers of the stomach. Acute gastritis may be caused by dietary indiscretions, excessive intake of alcohol, the ingestion of irritating drugs, food poisoning, and infectious diseases. The chief symptoms are severe upper-abdominal pain, nausea, vomiting, loss of appetite, thirst, and diarrhea; the illness develops suddenly and subsides rapidly. The only treatment necessary is temporary avoidance of food, followed by a nonirritating diet, sedatives, and antispasmodics; rarely, fluids by intravenous injection may be required. The ingestion of corrosives (acids, alkalis) causes a severe chemical gastritis, necessitating immediate emptying and thorough washing of the stomach and then general supportive care.

Chronic gastritis may be caused by prolonged use of aspirin or nonsteroidal anti-inflammatory drugs (NSAIDs), infection with *Helicobacter pylori* (the bacteria that also causes peptic ulcers), or pernicious anemia. The symptoms are indefinite and often resemble those of functional digestive disorders. The symptoms may include discomfort, fullness or pain in the upper abdomen, and poor appetite. The treatment for chronic gastritis depends on its cause; antacids will usually eliminate symptoms and promote healing. Antibiotics are used to treat chronic gastritis caused by *H. pylori* infection. Chronic gastritis caused by pernicious anemia is treated with vitamin B<sub>12</sub>. Irritating drugs that cause the disease are discontinued.

**gastrocnemius muscle**, also called LEG TRICEPS, large posterior muscle of the calf of the leg. It originates at the back of the femur (thighbone) and patella (kneecap) and, joining the soleus (another muscle of the calf), is attached to the Achilles tendon at the heel.

**gastroenteritis**, acute infectious syndrome of the stomach lining and the intestine. It is characterized by diarrhea, vomiting, and abdominal cramps. Other symptoms can include nausea, fever, and chills. The severity of gastroenteritis varies from a sudden but transient attack of diarrhea to a life-threatening disease with severe dehydration.

Numerous viruses, bacteria, and parasites can cause gastroenteritis, and the specific cause of the disease can be identified in only about two-thirds of cases. Microorganisms cause gastroenteritis by secreting toxins that stimulate excessive loss of water and electrolytes, causing watery diarrhea; or by directly invading the walls of the gut, triggering an inflammatory response that destroys the balance between the digestive system's absorption of nutrients and the secretion of wastes.

Among the forms of gastroenteritis besides the aforementioned are classic food poisoning, cholera, and traveler's diarrhea, which develops within a few days after traveling to a country or region that has unsanitary water or food. Traveler's diarrhea is caused by exposure to enterotoxin-producing strains of the common intestinal bacterium *Escherichia coli*.

The treatment of gastroenteritis depends on the cause and the severity of symptoms and may include antibiotics or simply supportive care. Adults tend to have milder cases of the illness than do children and the very old, who run the risk of dehydration due to diarrhea and vomiting.

**gastroenterology**, medical specialty concerned with the digestive system and its diseases. The first scientific studies of the digestive system were performed by Jan Baptist van Helmont in the 17th century. In 1833 the publication of William Beaumont's observations shed new light on the nature of gastric juice and the digestive process in general.

A major advance in treatment in the 19th century was the use of gastric lavage (washing out of the stomach) to treat stomach poisoning; this became a standard treatment for all

forms of gastric irritation, and the long tube used to introduce the lavage fluid was also adapted to view the stomach for diagnostic use. The first truly useful instrument for viewing the stomach, a tube that could be inserted down the esophagus and upon which a light was mounted to illuminate the area visualized, was invented in about 1889; this rigid instrument was soon replaced by the flexible gastroscope, developed by Rudolph Schindler in 1932, and then by the flexible fibre-optic gastroscope, developed by Basil Hirschowitz in 1957. In the 1890s Walter Cannon used X rays to visualize the stomach and digestive organs, and he also used bismuth salts to coat the gastrointestinal lining and thus make digestive movements visible by fluoroscopy.

Modern-day gastroenterologists diagnose and treat the diseases and disorders of the esophagus, stomach, intestines, liver, biliary tract, and pancreas. Among the most common disorders they must deal with are gastroesophageal reflux disease (GERD), gastric and duodenal ulcers, malignant tumours, inflammatory bowel diseases, colorectal cancer, and rectal disorders.

**gastroesophageal reflux disease (GERD)**, relatively common digestive disorder characterized by frequent passage of gastric contents from the stomach back into the esophagus. The most common symptom of GERD is heartburn, a burning sensation in the chest and upper abdomen. Other symptoms may include coughing, frequent clearing of the throat, difficulty in swallowing (dysphagia), hoarseness, or exacerbation of asthma.

Causes of GERD include relaxation of the muscle that connects the esophagus and the stomach (lower esophageal sphincter), delayed emptying of the esophagus or stomach, hiatal hernia, obesity, or pregnancy. GERD can be treated with antacids or with medications that inhibit acid production, such as histamine receptor antagonists (Zantac™, Pepcid™) or proton pump inhibitors (Prilosec™, Prevacid™). Treatment also includes dietary and lifestyle changes such as not eating for three hours before bedtime, avoiding acidic or fatty foods or beverages, cessation of smoking, and weight loss. Surgery may be necessary in cases of severe reflux. If GERD is not treated, squamous cells of the esophageal lining may be replaced with columnar cells, a condition known as Barrett's esophagus; some persons with Barrett's esophagus develop esophageal cancer.

**gastrointestinal tract**, that portion of the digestive system which includes the stomach, the small intestine, and the large intestine (*qq.v.*). See also digestion.

**gastronomy**, the art of selecting, preparing, serving, and enjoying fine food.

A brief treatment of gastronomy follows. For full treatment, see MACROPAEDIA: Gastronomy.

Prehistoric man took a major step toward the development of gastronomy with the use of fire to cook his food. Two early centres of gastronomy were Rome and China. Although the Romans were noted for the vulgarity and ostentation of their banquets, their cuisine seems to have been one of memorable sophistication. In the Orient, references are made to a fully developed gastronomy as early as the 5th century BC. Through trade, war, and cultural assimilation, this gastronomy spread to Japan, Korea, and much of Southeast Asia.

The foundations of Western gastronomy were laid during the Renaissance. The marriage of Catherine de Médicis to the future King Henry II of France occasioned an influx of sophisticated Italian culinary principles to France. Refined further during the peri-

ods of the kings Louis XIV, XV, and XVI, the French Grande Cuisine reached its apex in the works and writings of Marie-Antoine Carême, the first major codifier of French cuisine; Georges-Auguste Escoffier, who worked to simplify and refine a sometimes florid culinary style; and Prosper Montagné, who created *Larousse Gastronomique* (1938), the basic encyclopaedia of French gastronomy.

In France and China, countries long noted for their use of a variety of foods, beef, lamb, pork, fowl of all varieties, fish and shellfish, herbs, roots, legumes, cereals, and more are staples. In the Pacific, coconut and taro form the basis of many dishes, and in Africa, peanuts (groundnuts) are widely used. Yogurt, eggplant, olives, and lamb are basic to the Middle Eastern diet. In the cooking of India and Indonesia, spices are a distinctive feature. Corn (maize) is central to the cuisine of much of Latin America. In Italy, together with pastas of all shapes and sizes, rice and polenta serve as staples in many regions. Salmon and herring are two of the more popular varieties of fish featured in the northern countries of Europe. In Japan, also, fish is widely used, as are vegetables of all types. In Germany, game and particularly sausages abound, with varieties ranging from the simple *Weisswurst* to elaborate preparations involving venison, boar, and wild fowl.

Regardless of regional differences or interpretations, the primary consideration in the selection of ingredients is freshness. Refrigeration and transport by air have increased the variety of fresh foods available in many parts of the world. Although modern food-processing technologies (canning, freeze-drying, etc.) have made possible the use of ingredients not regionally or seasonally available, these foods are generally regarded as substitutes for fresh ingredients. The care given to the processing and cooking of the chosen ingredients is an extension of the care taken in their selection. Involved here are techniques, recipes, and menus that are frequently learned only through much practice and experience. The paper-thin slicing of raw fish for Japanese sushi and sashimi and the carving of floral-shaped garnitures for the German *Sulzkoteletten* (pork chops in aspic) are techniques that may take years to perfect. Similarly, the organization and preparation of a menu for a state banquet will frequently require the attention of a staff of highly trained professionals.

The art of gastronomy is not limited, however, to intricate methods of preparation and cooking. Many of its expressions are well within the capabilities and budgets of many households. The paella (a rice dish served with clams, mussels, chicken, sausages, shrimp, and saffron), for which Spain is noted, and the Indonesian rijsttafel (a platter of seasoned rice surrounded by smaller dishes of various meats and condiments) are complicated but can nonetheless be prepared at home.

There are other considerations involved in the preparation of food: complementarity or opposition of taste, as in the sweet and pungent dishes of the Orient; textures, as in the crispness of the pickle and onion accompanying smoked fish on a Danish *smorrebrod* (open-faced sandwich); colour harmony and accent, as in the white and green Italian pasta. The sense of accomplishment in melding disparate elements together into an appealing whole, the sensual enjoyment of tastes, the appreciation of harmonies and balances, and the recognition and appreciation of subtleties and nuances all enhance the pleasures of the table.

**gastropod**, any member of the class Gastropoda, the largest group of the phylum Mollusca, consisting of about 60,000 species.

A brief treatment of gastropods follows. For full treatment, see MACROPAEDIA: Mollusks.

Gastropods are distributed worldwide, occurring in most marine, freshwater, and terrestrial environments. A typical gastropod, such as a sea snail, has a large foot with a flat sole for crawling, a single coiled shell that covers the viscera, and a head bearing a pair of eyes and tentacles. During development, the viscera, in many species rotate 180° relative to the head and foot (in a process called torsion) so that the gills and anus lie above the head. Gastropods are so diverse that there are many exceptions to these group characteristics. Sea slugs and garden slugs, for example, lack shells, while the species of one genus of snails have shells consisting of two halves like that of a bivalve (*q.v.*).

Most gastropods feed by using a radula, a ribbon of small horny teeth that tear the food into pieces that are then collected by the lips. In many marine snails, the mouth and radula are situated at the end of an extensible proboscis (*i.e.*, a tubular sucking organ). Gastropods may be herbivorous or carnivorous, predatory or parasitic, or they may feed on plankton and deposits of detritus filtered from the water.

Gastropods are commonly divided into three major groups: prosobranchs, opisthobranchs, and pulmonates. The prosobranchs include most shelled marine snails as well as some terrestrial forms; they characteristically have gills in the cavity of the body wall (mantle) and a lidlike structure (operculum) attached to the foot for closing the opening of the shell. The opisthobranchs, which include seahares, nudibranchs (seaslugs), and bubble shells, either lack a shell or have a reduced shell that is partly embedded in the body. The pulmonates, consisting of most land and freshwater snails and slugs, have no gills and use the mantle cavity as a lung. For further information on members of the gastropod group, see opisthobranch; prosobranch; pulmonate.

**gastrotrich**, any of about 1,800 species of the class Gastrotricha, a group of microscopic aquatic invertebrates belonging to the phylum Aschelminthes. They occur in salt water and fresh water and also on sandy seashores.

The body of a gastrotrich, which ranges in size from 0.1 to 1.5 millimetres (0.004 to 0.06 inch), is covered by a cuticle that is often scaly and spiny. The head is swollen and lobelike. Adhesive tubules are used for anchorage. Cilia—especially on the head and on the ventral, or bottom, surface—are used for locomotion.

Bacteria, organic debris, and certain protozoans (diatoms) are ingested by a sucking muscular pharynx, which leads to the intestine. Many species are hermaphroditic (*i.e.*, reproductive organs of both sexes occur in the same individual). One group, Chaetonotoidea, has only parthenogenetic females (*i.e.*, they produce unfertilized eggs that, in turn, produce females). Two types of eggs are known for freshwater gastrotrichs: tachyblastic eggs, which develop immediately, and opsiblastic eggs, which remain inactive for long periods and can survive dry and freezing conditions.

**gastrula**, early multicellular embryo, composed of two or more germinal layers of cells from which the various organs later derive. The gastrula develops from the hollow, single-layered ball of cells called a blastula which itself is the product of the repeated cell division, or cleavage, of a fertilized egg. This cleavage is followed by a period of development in which the most significant events are movements of cells relative to one another.

An adult, multicellular animal typically possesses a concentric arrangement of tissues of the body. These adult tissues are derived from three embryonic cell layers called germinal layers; the outer layer is the ectoderm, the middle layer is the mesoderm, and the inner-

most layer is the endoderm. Gastrulation involves the drastic reshuffling of the blastula's cells into these three germinal layers, which in turn become the various organ systems of the animal's body.

Gastrulation consists of the inward movement, or invagination, of the cells of one side of the blastula until they are juxtaposed to the opposite side; thus the spherical embryo is converted into a double-walled cup, or gastrula. The involuted part of the blastula, lining the inside of the double-walled cup, gives rise to the endoderm and the mesoderm, and the cells remaining on the exterior of the cup become the ectoderm. From this ectoderm, or outside layer, will be derived the outer part of the animal's integument (the skin covering) and its nervous system and sense organs.

The inward movement of one side of the blastula's cells has contracted or eliminated the blastocoel, which was the cavity of the blastula, but a new cavity is formed in the hollow of the cup. This primitive gut cavity is the endoderm and forms the rudiment of the animal's future gut and many of its associated digestive organs and glands. Before either ectoderm or endoderm begins to differentiate into their future structures, however, a third layer of cells lying between them becomes apparent. This third layer is the mesoderm, from which will later be derived the bulk of the animal's musculature and, in most cases, its excretory system and reproductive system.

The diversification of cells in the embryo progresses rapidly during and after gastrulation. The visible effect is that the germinal layers become further subdivided into aggregations of cells that assume the rudimentary form of various organs and organ systems of the embryo. Thus the period of gastrulation is followed by the period of organ formation, or organogenesis.

**Gat** (Libya): see Ghât.

**Gatchina**, formerly (until 1929) KHOTCHINO, or (1929–44) KRASNOGARDEYSK, city, St. Petersburg oblast (province), northwestern Russia, lying 15 miles (24 km) southwest of St. Petersburg. The first mention of Khotchino dates from 1499, when it was a possession of Novgorod. Later it belonged to Livonia and Sweden. After 1721 it was returned to Russia and in the 1720s belonged to the sister of Peter I the Great, Natalia. The town grew only after the building, between 1766 and 1772, of a summer palace there for Catherine II's favourite, Count Orlov. The palace was designed by the Italian architect Antonio Rinaldi; it had about 600 rooms, a theatre, and many works of art, and was also surrounded by a fine park. Upon Orlov's disgrace the palace passed to Catherine's son, Paul I, who transformed it into a combination of palace, fortress, and barracks. Although badly damaged during World War II, the palace was restored and is now a museum. The modern city is a railway junction, with machine building, metalworking, and light industries. Pop. (1991 est.) 81,300.

**gate**, in hydraulic engineering, movable barrier for controlling the passage of fluid through a channel or sluice. River and canal locks have a pair of gates at each end. When closed, the gates meet at an obtuse angle that points upstream in order to resist the water pressure. When opened, they swing into recesses in the walls of the lock. Gates also regulate the outflow of water from storage reservoirs and through, around, or over dams. Leaf gates, planes perpendicular to the direction of fluid flow, open either by swinging about one hinged side or by sliding upward. Radial gates are segments of cylinders that lift entirely clear of the water. The rolling gate, often used on the crest of a dam, is raised by rolling it up the inclined face of a pier.

**Gate Theatre**, Dublin dramatic company, founded in 1928 by Hilton Edwards and Micheál MacLiammóir, whose repertoire included works from many periods and countries, unlike that of the established Abbey Theatre. From 1928 to 1930 the Gate Theatre made its home at the Peacock, then moved to its own building. The Abbey and the Irish National Theatre Society had provided a stage for national playwrights who concentrated on realism and everyday Irish life, seeking isolation from the European theatre. The Gate, on the other hand, sought to foster the development of writers with new subjects and styles, and its performances resembled those in other parts of Europe.

Edwards and MacLiammóir expanded on the National Theatre Society's work, producing classics and continental plays that attracted such actors as James Mason and Orson Welles. Their repertoire embraced a wide range of writers, from William Shakespeare, Henrik Ibsen, August Strindberg, and George Bernard Shaw to Denis Johnston, An Philibin, Mary Manning, and David Sears. Longford Productions, a company with comparable goals, shared the theatre from 1936 to 1961. Beginning in 1969, the Gate received a government subsidy that allowed it to renovate the theatre and continue producing its eclectic repertoire.

**gateleg table**, type of table first used in England in the 16th century. The top had a fixed section and one or two hinged sections, which, when not in use, folded back onto the fixed

Gateleg table of turned oak, English, c. 1660  
By courtesy of Country Life, London

section or were allowed to hang vertically. The hinged section, or flap, was supported on pivoted legs joined at the top and bottom by stretchers and so constituting a gate. Large flaps had two supports, which had the advantage of providing freer leg space in the centre.

A variant introduced in the third quarter of the 18th century is the spider-leg table, in which the turned legs are exceptionally slender. In the 18th century, gateleg tables were popular in the American colonies, where local variations were introduced.

**Gates, Bill**, in full WILLIAM HENRY GATES III (b. Oct. 28, 1955, Seattle, Wash., U.S.), American computer programmer and entrepreneur who cofounded Microsoft Corporation, the world's largest personal-computer software company.

Gates wrote his first software program at the age of 13. In high school he helped form a group of programmers who computerized their school's payroll system and founded Traf-O-Data, a company that sold traffic-counting systems to local governments. In 1975 Gates, then a sophomore at Harvard University, joined his hometown friend Paul G. Allen to develop software for the first microcomputers. They began by adapting BASIC, a popular programming language used on large computers, for use on microcomputers. With the success of this project, Gates left Harvard during his junior year and, with Allen, formed Microsoft. Gates's sway over the infant microcomputer industry greatly in-

creased when Microsoft licensed an operating system called MS-DOS to International Business Machines Corporation—then the world's biggest computer supplier and industry pacesetter—for use on its first microcomputer, the IBM PC (personal computer). After the machine's release in 1981, IBM quickly set the technical standard for the PC industry, and MS-DOS likewise pushed out competing operating systems. While Microsoft's independence strained relations with IBM, Gates deftly manipulated the larger company so that it became permanently dependent on him for crucial software. Makers of IBM-compatible PCs, or clones, also turned to Microsoft for their basic software. By the start of the 1990s he had become the PC industry's ultimate kingmaker.

Largely on the strength of Microsoft's success, Gates amassed a huge paper fortune as the company's largest individual shareholder. He became a paper billionaire in 1986, and within a decade his net worth had reached into the tens of billions of dollars—making him by some estimates the world's richest private individual. With few interests beyond software and the potential of information technology, Gates at first preferred to stay out of the public eye, handling civic and philanthropic affairs indirectly through one of his foundations. Nevertheless, as Microsoft's power and reputation grew, and especially as it attracted the attention of the U.S. Justice Department's antitrust division, Gates, with some reluctance, became a more public figure. Rivals (particularly in competing companies in Silicon Valley) portrayed him as driven, duplicitous, and determined to profit from virtually every electronic transaction in the world. His supporters, on the other hand, celebrated his uncanny business acumen, his flexibility, and his boundless appetite for finding new ways to make computers and electronics more useful through software.

All of these qualities were evident in Gates's nimble response to the sudden public interest in the Internet. Beginning in 1995 and 1996, Gates feverishly refocused Microsoft on the development of consumer and enterprise software solutions for the Internet, developed the Windows CE operating system platform for networking noncomputer devices such as home televisions and personal digital assistants, created the Microsoft Network to compete with America Online and other Internet providers, and, through Gates's company Corbis, acquired the huge Bettmann photo archives and other collections for use in electronic distribution.

**Gates, Horatio** (b. c. 1728, Maldon, Essex, Eng.—d. April 10, 1806, New York, N.Y., U.S.), English-born American general in the U.S. War of Independence (1775–83) whose victory over the British at the Battle of Saratoga (fall 1777) turned the tide of victory in behalf of the Revolutionaries.

Gates first served in North America in the French and Indian War (1754–63), emerged as

Horatio Gates, detail of an engraving  
By courtesy of the Library of Congress, Washington D.C.

a major, and returned to England. In 1772 he immigrated to the region that is now West Virginia. Sympathizing with colonial complaints against the crown, in 1775 he was made adjutant general of the Continental Army, and in 1777 he superseded General Philip Schuyler in northern New York. In the two battles of Saratoga his army forced General John Burgoyne to surrender, partly, however, because of the previous maneuvers of Schuyler and the initiative of General Benedict Arnold. Congress next elected Gates president of the Board of War. At the same time a group of army officers, among them General Thomas Conway, became involved in a plan to replace General George Washington with Gates. The "Conway Cabal" soon collapsed, and in the spring of 1778 Gates returned to his command in New York. Transferred to the south (June 1780), Gates was disastrously defeated by Lord Cornwallis at the Battle of Camden, S.C., on August 16. An official inquiry into his conduct was ordered but charges were never pressed. After the war Gates freed his slaves, moved to New York, and served one term in the state legislature.

Consult the INDEX first

**Gates, John Warne** (b. May 8, 1855, Turner Junction, Ill., U.S.—d. Aug. 9, 1911, Paris, France), American financier and steel magnate who leveraged an \$8,000 investment in a barbed-wire plant into the \$90,000,000 American Steel & Wire Co.

Dissatisfied with his partnership in a country hardware store at the age of 19 and impressed with the possibilities of a new product known as barbed wire, Gates became a traveling barbed-wire salesman. To convince the doubting Texas cattlemen of the value of his fencing wire, Gates dramatically challenged the ranchers to test his product by enclosing their wild range steers in a barbed-wire corral in the middle of San Antonio. The stunt was a success, and he immediately sold hundreds of miles of wire. With \$8,000, he and a partner launched their own wire plant. Gates bought out his partner in 1880 and began the Southern Wire Co. In 1882 he merged with his major competitor, creating the Braddock Wire Co., which quickly acquired many of its smaller rival firms.

Gates formed the American Steel & Wire Co. of Illinois in 1897 with a capital of \$24,000,000 and then the American Steel & Wire Co. of New Jersey with a capital of \$90,000,000. With a virtual monopoly on barbed wire, Gates used his huge fortune to acquire interests in other industries. His bold investment approach to the stock market earned him the nickname of "Bct-A-Million" Gates. His investments also included iron, steel, railroads, and extensive real estate holdings in Texas. He virtually owned the city of Port Arthur, Texas, which he helped transform from a frontier watering hole to a major Gulf port city.

**Gates of Paradise**, Italian PORTA DEL PARADISO, the pair of gilded bronze doors (1425–52) designed by the sculptor Lorenzo Ghiberti for the east entrance of the Baptistery of San Giovanni in Florence. Each wing of the Gates of Paradise contains five rectangular reliefs of scenes from the Old Testament between figured borders containing statuettes in niches and medallions with busts. The entire surface of the doors is gilt. The classically modeled figures within the reliefs are placed in landscapes or in perspectively rendered architecture to suggest a greater depth to the reliefs than ac-

tually exists. The 10 relief panels are among the greatest works of Early Renaissance sculpture. They demonstrate the mastery of linear perspective and the classical idiom achieved in Florence by the early 15th century.

**Gates of the Arctic National Park and Preserve**, formerly GATES OF THE ARCTIC NATIONAL MONUMENT, national park and preserve in northern Alaska, U.S., lying entirely north of the Arctic Circle. Proclaimed a national monument in 1978, the area underwent boundary changes and the name was altered in 1980. It includes a portion of the Central Brooks Range, the northernmost extension of the Rocky Mountains, characterized by jagged peaks, gentle Arctic valleys, wild rivers, and many lakes. The southern slopes are forested, contrasting with the barren northern reaches at the edge of Alaska's North Slope. Wildlife includes caribou, grizzly bears, Dall sheep, moose, and wolves. The total area is 11,756 square miles (30,448 square km).

**Gateshead**, district and borough, metropolitan area of Tyne and Wear, England. The small settlement grew up at the southern end of a medieval bridge, opposite the fortress (later city) of Newcastle upon Tyne, and was under the jurisdiction of the bishop of Durham. Gateshead has iron, steel, engineering, and food industries. The Team Valley Trading Estate, accommodating small-scale light industries, was developed after 1936 on a 700-acre (270-hectare) site. Area 55 square miles (143 square km). Pop. (1981) town, 91,893; (1991 prelim.) district, 196,500.

**Gath**, one of the five royal cities of the Philistines, the exact location of which in modern Israel has not been determined. The name occurs several times in the Old Testament, especially in connection with the history of David. Goliath, the Philistine champion, came from Gath.

The records of Sargon II of Assyria show that he took it in 712 bc. Gath was evidently a place of importance, a walled city (2 Chronicles 26:6), but its exact location has been lost since the time of Sennacherib (7th century bc). The *Onomasticon* of Eusebius fixes the site near the Roman road 5 miles (8 km) from Eleutheropolis (Bet Guvrin) on the way to Diospolis (Lod). The excavations seeking it in this and other areas, however, have proved disappointing, and all identifications of Gath are, to date, highly questionable.

**Gatineau**, city, Outaouais region, southwestern Quebec province, Canada. It is situated on the north bank of the Ottawa River, opposite Ottawa and adjacent to Hull, near the mouth of the Gatineau River. The city derives its name from the river, which itself was named for Nicolas Gatineau, a fur trader who reportedly drowned in its waters about 1683. Gatineau was originally a part of Templeton West but was separately incorporated as a village in 1933 and became a town in 1946 and a city in 1975. Its major industry is a large pulp and paper mill, built in 1927, that processes logs floated down to it on the Gatineau River. The city's other products are alcohol and building materials (plywood, fibreboard, acoustic tiles). Gatineau Provincial Park is located to the northwest. Pop. (1991) 92,284.

**Gatineau River**, French RIVIÈRE GATINEAU, river in Outaouais region, southwestern Quebec province, Canada. The river rises in a chain of lakes north of Baskatong Reservoir and flows generally southward for 240 miles (390 km) to join the Ottawa River at Hull. It was named for Nicolas Gatineau, a fur trader who is reputed to have drowned there about 1683. Having served for centuries as a major artery for the lumber trade, the Gatineau has

also become an important source of hydroelectric power in the 20th century.

**Gatling, Richard Jordan** (b. Sept. 12, 1818, Maney's Neck, N.C., U.S.—d. Feb. 26, 1903, New York, N.Y.), American inventor best known for his invention of the Gatling gun (*q.v.*), a crank-operated, multibarrel machine gun, which he patented in 1862.

Gatling's career as an inventor began when he assisted his father in the construction and perfecting of machines for sowing cotton seeds and for thinning cotton plants. In 1839 he perfected a practical screw propeller for steamboats, only to find that a patent had been granted to John Ericsson for a similar invention a few months earlier. He established himself in St. Louis, Mo., in 1844, and, taking the cotton-sowing machine as a basis, he adapted it for sowing rice, wheat, and other grains. The introduction of these machines did much to revolutionize the agricultural system in the country.

Becoming interested in the study of medicine during an attack of smallpox, Gatling completed a course at the Ohio Medical College in 1850. In the same year, he invented a hemp-breaking machine, and in 1857 a steam plow. At the outbreak of the American Civil War he devoted himself at once to the perfecting of firearms. In 1861 he conceived the idea of the rapid-fire machine gun that is associated with his name. By 1862 he had succeeded in perfecting the weapon; but the war was practically over before the federal authorities consented to its official adoption.

**Gatling gun**, hand-driven machine gun, the first to solve the problems of loading, reliability, and the firing of sustained bursts. It was invented by Richard J. Gatling during the American Civil War (about 1862). After early experiments with a single barrel using paper cartridges (which had to have a separate percussion cap), he saw in the newly invented brass cartridge (which had its own percussion cap) an opportunity to fashion a truly rapid-fire weapon. Gatling contrived a cluster of 10 barrels, each of which, when rotated by a crank, was loaded and fired once during a complete rotation. The barrels were loaded by gravity and the camming action of the cartridge container, located directly above the gun. Each barrel was loaded and fired during a half-rotation around the central shaft, and the spent cases were ejected during the second half-rotation.

Smithsonian Institution Photo No. P651015

Without equal in the era of hand-operated machine guns, the Gatling gun could fire 3,000 rounds per minute if externally powered. It and all other hand-operated machine guns were made obsolete by the development of recoil- and gas-operated guns that followed the invention of smokeless gunpowder. *See also* machine gun.

**Gatooma** (Zimbabwe): *see* Kadoma.

**GATT**: *see* General Agreement on Tariffs and Trade.

**Gattamelata**, also called EQUESTRIAN MONUMENT OF ERASMO DA NARNI, bronze statue of the Venetian condottiere Erasmo da Narni, (popularly known as Gattamelata, meaning "honeyed cat") by the 15th-century Italian Early Renaissance sculptor Donatello. It was completed between 1447 and 1450 but was not installed on its pedestal in the Piazza del Santo in front of the Basilica of Sant'Antonio in Padua, Italy, until 1453. The statue established a prototype for equestrian monuments in the West.

**Gatun Lake**, Spanish LAGO GATÚN, long artificial lake in Panama, constituting part of the Panama Canal system; its area is 166 square miles (430 square km). It was formed by damming the Chagres River and its smaller affluents at Gatun at the north end of the lake. Its dam (completed 1912) and spillway, a key structure of the Panama Canal, operate at a range of 5 feet (1.5 m) between water levels of 87 and 82 feet (26.5 and 25 m) above sea level. The lake's main function is to hold sufficient water in the Gaillard Cut to the south, a gorge blasted through the Cordillera, for canal passage and for use in the canal's locks during dry spells. In the centre of the lake is Guacha Island, a wildlife sanctuary.

**Gaua** (Vanuatu): *see* Santa Maria.

**Gaucher's disease**, rare inherited metabolic disorder characterized by anemia, mental and neurologic impairment, yellowish pigmentation of the skin, and bone deterioration resulting in pathological fractures. Gaucher's disease results when a defect in the body's synthesis of the enzyme glucocerebrosidase allows the lipid glucocerebroside to accumulate in the body's storage cells. Large, wrinkled-appearing cells, called Gaucher's cells, are usually found in the bone marrow. The disease is transmitted as an autosomal recessive trait.

There are three forms of Gaucher's disease: adult, or type 1; infantile, or type 2; and juvenile, or type 3. The adult form is by far the most common of the three and has an especially high incidence among Ashkenazic Jews (1 in 2,500 births). Its chief symptoms are an enlarged spleen and erosion of the long bones. These symptoms are often mild in effect, though, and the lifespan of persons afflicted with type 1 is only slightly reduced on average. The infantile, or type 2, form results in enlargement of the spleen and liver, erosion of the long bones, and mental retardation in the first months of life; death from respiratory failure usually occurs by the second birthday. The juvenile, or type 3, form is similar to type 2 but has less effect on the central nervous system and develops more slowly; death usually occurs in early adolescence. Most cases of types 2 and 3 are apparently caused by a mutation in a gene located on chromosome 1.

**Gauches, Cartel des** (French: "Coalition of the Left"), in the French Third Republic (1870–1940), a coalition of left-wing parties in the Chamber of Deputies (lower house of the legislature). It governed France from 1924 to 1926.

The Socialist Party, which usually disdained association with the bourgeois parties of the right, joined an electoral alliance with the Radicals, who had dominated prewar ministries. Together they formed the Cartel in opposition to the Bloc National—the right-wing nationalist group elected at the end of World War I—and defeated it in the elections of May 11, 1924. In the victory they gained more than 300 seats to 200 for the Bloc National and then set up a cabinet under the Radical leader Edouard Herriot. In an attempt to unify the left, the Radical leaders followed a policy of anticlericalism, trying to enforce

secular education in strongly religious Alsace-Lorraine, which had been recently recovered from Germany. In international affairs, a policy of security through negotiation (in contrast to the militant stance of the Bloc National) was pursued by the foreign minister Aristide Briand.

A financial crisis caused by continuing inflation led to the Cartel's downfall. The Socialists, demanding a direct tax to meet government expenses, found themselves in disagreement with the Radicals, who hesitated to move in any direction, especially in support of a proposal so violently opposed by business interests. On April 10, 1925, the Herriot government fell. Succeeding ministries under Paul Painlevé and Briand were able neither to solve the financial problem nor to maintain the fragile unity of the Cartel.

**gaucho**, the nomadic and colourful horseman and cowhand of the Argentine and Uruguayan Pampas (grasslands), who flourished from the mid-18th to the mid-19th century and has remained a folk hero similar to the cowboy in western North America.

Gauchos herding cattle in Uruguay  
Carl Frank—Photo Researchers/EB Inc

Gauchos were usually mestizos (persons of mixed European and Indian ancestry) but sometimes were white, black, or mulatto (of mixed black and white ancestry). From their own ballads and legends a literature of the gaucho—*la literatura gauchesca*—grew and became an important part of the Argentine cultural tradition. Beginning late in the 19th century, after the heyday of the gauchos, Argentine writers celebrated them. Examples include José Hernández' epic poem *El gaucho Martín Fierro* (1872) and Ricardo Güiraldes' novel *Don Segundo Sombra* (1926).

In the mid-18th century, when British, Dutch, French, and Portuguese traders provided a profitable contraband business in hides and tallow in the frontier regions around Buenos Aires, gauchos arose to hunt the large herds of escaped horses and cattle that had roamed freely, bred prodigiously, and remained safe from predators on the extensive Pampas. Gaucho weapons were the lasso, knife, and *boleadoras* (or *bolas*), a device made of leather cords and three iron balls or stones that was thrown at the legs of an animal to entwine and immobilize it. Gauchos subsisted largely on meat. Their costume, still worn by modern Argentine cowhands, included a *chiripa* girding the waist, a woolen poncho, and long, accordion-pleated trousers, called *bombachas*, gathered at the ankles and covering the tops of high leather boots. The gauchos lived in small mud huts, roofed with grass mats, and slept on piles of hides. Their marriages were seldom solemnized, and their religious beliefs consisted mainly of age-old superstitions varnished with Roman Catholicism. Their pastimes included gambling, drinking, playing the guitar, and singing doggerel verses about their prowess in hunting, fighting, and lovemaking.

By the end of the 18th century, private owners had acquired the half-wild livestock on

the Pampas and hired the gauchos as skilled animal handlers. By the later 19th century the Pampas had been fenced into huge *estancias* (estates), and the old pastoral economy had given way to more intensive use of the land as purebred animals replaced the scrub herds and as alfalfa was grown to feed them. The once free-spirited gaucho thus became a farm-hand or peon.

In the early 19th century the gauchos had been the mainstay of the armies of the Río de la Plata region, which first had thrown off the Spanish colonial regime and had then engaged in decades-long internal struggles between rival caudillos (provincial military leaders). An unruly group of horsemen called the *montonera* fought in these wars, usually under the federalist caudillos of the provinces outside of Buenos Aires. The people of the Río Grande do Sul state in Brazil are called *gaúchos*.

**gaucho literature**, Spanish-American poetic genre that imitates the *payadas* ("ballads") traditionally sung to guitar accompaniment by the wandering gaucho minstrels of Argentina and Uruguay. By extension, the term includes the body of South American literature that treats the way of life and philosophy of the itinerant gauchos. Long a part of South American folk literature, gaucho lore became the subject of some of the best verse of the 19th-century Romantic period. The gaucho's story found its highest poetic expression in Rafael Obligado's three poems (1887) on the legendary gaucho minstrel Santos Vega. The gaucho was humorously portrayed in the mock epic *Fausto* (1866) by Estanislao del Campo. Later the gaucho aroused the national conscience and received epic treatment in the classic poem *El gaucho Martín Fierro* (1872) by José Hernández.

In prose the first serious use of gaucho lore was made by Domingo Faustino Sarmiento in *Facundo* (1845; "Eloquent"), a classic account of the cultural clash between the Pampas and the civilizing forces of the city. This theme of the clash between the old and the new informed a rich literature ranging from the sombre descriptive pages of Uruguay's short-story writer Javier de Viana and the keen psychological portrayal of rural types in *El terruño* (1916; "The Native Soil") by Carlos Reyles, also of Uruguay, to the simple humorous narrative of *El inglés de los güesos* (1924; "The Englishman of the Bones") by Argentina's Benito Lynch and the image-studded, evocative prose epic of the gaucho *Don Segundo Sombra* (1926) by the Argentine Ricardo Güiraldes. In *Doña Bárbara* (1929), Rómulo Gallegos, one of South America's masters of plot technique, gave a dramatic and poetic depiction of similar forces at work on the Venezuelan Llanos.

**Gauða**, a city, a country, and a literary style in ancient India. The city is better-known un-

der its Anglicized form, Gaur. Its first recorded reference is by the grammarian Pāṇini (5th century BC), and its location may be inferred to have been in eastern India.

The name Gauða, in Sanskrit literature, is commonly applied to a country in what is now eastern India. In this sense it occurs fairly widely in the *Purāṇas* and other sources. It seems always to have coincided roughly with an area south of the Ganges River in West Bengal. The name is often used in a wider sense for the western parts of Bengal, as opposed to Vaṅga (modern Bangladesh).

From early times the inhabitants of Gauða were known as seafarers. In literature, the poetic style Gauða or Gaudī, also known as *Prācyā* (eastern), is described by Daṇḍin in his work on poetics, *Kāvya-darśa*.

**Gaudí (i Cornet), Antoni** (Catalan), Spanish ANTONIO GAUDÍ Y CORNET (b. June 25, 1852, Reus, Spain—d. June 10, 1926, Barcelona), Catalan architect whose distinctive style is characterized by freedom of form, voluptuous colour and texture, and organic unity. Gaudí worked almost entirely in or near Barcelona. Much of his career was occupied with the construction of the Expiatory Temple of the Holy Family (*Sagrada Família*), which was unfinished at his death in 1926.

*Life.* Gaudí was born in provincial Catalan on the Mediterranean coast of Spain. Of humble origins, he was the son of a coppersmith who was to live with him in later life, together with a niece; Gaudí never married.

Showing an early interest in architecture, he went in 1869/70 to study in Barcelona, then the political and intellectual centre of Catalonia as well as Spain's most modern city. He did not graduate until eight years later, his studies having been interrupted by military service and other intermittent activities.

Gaudí's style of architecture went through several phases. On emergence from the Provincial School of Architecture in Barcelona in 1878, he practiced a rather florid Victorianism that had been evident in his school projects, but he quickly developed a manner of composing by means of unprecedented juxtapositions of geometric masses, the surfaces of which were highly animated with patterned brick or stone, gay ceramic tiles, and floral or reptilian metalwork. The general effect, although not the details, is Moorish—or Mudéjar, as Spain's special mixture of Muslim and Christian design is called. Examples of his Mudéjar style are the *Casa Vicens* (1878–80) and "El Caprieho" (1883–85) and the Güell Estate and Güell Palace of the later 1880s, all but "El Caprieho" located in Barcelona. Next, Gaudí experimented with the dynamic possibilities of historic styles: the Gothic in

The Colonia Güell Church by Antoni Gaudí, 1898–c. 1915; in Santa Coloma de Cervelló, Spain

the Episcopal Palace, Astorga (1887–93) and Casa de los Botines, León (1892–94) and the Baroque in the Casa Calvet at Barcelona (1898–1904). But after 1902 his designs elude conventional stylistic nomenclature.

Except for certain overt symbols of nature or religion, Gaudí's buildings became essentially representations of their structure and materials. In his Villa Bell Esuard (1900–02) and the Güell Park (1900–14), in Barcelona, and in the Colonia Güell Church (1898–c. 1915), south of that city, he arrived at a type of structure that has come to be called equilibrated—that is, a structure designed to stand on its own without internal bracing, external buttressing, and the like—or, as Gaudí observed, as a tree stands. Among the primary elements of his system were piers and columns that tilt to transmit diagonal thrusts, and thin-shell, laminated tile vaults that exert very little thrust. Gaudí applied his equilibrated system to two multistoried Barcelona apartment buildings: the Casa Batlló (1904–06), a renovation that incorporated new equilibrated elements, notably the facade; and the Casa Milà (1905–10), the several floors of which are structured like clusters of tile lily pads with steel-beam veins. As was so often his practice, he designed the two buildings, in their shapes and surfaces, as metaphors of the mountainous and maritime character of Catalonia.

As an admired, if eccentric, architect, Gaudí was an important participant in the Catalan *Renaixensa*, an artistic revival of the arts and crafts combined with a political revival in the form of fervent anti-Castilian "Catalanism." Both movements sought to reinvigorate the way of life in Catalonia that had long been suppressed by the Castilian-dominated and Madrid-centred government in Spain. The religious symbol of the *Renaixensa* in Barcelona was the church of the Holy Family, a project that was to occupy Gaudí throughout his entire career. He was commissioned to build this church as early as 1883, but he did not live to see it finished. Working on it, he became increasingly pious; after 1910 he abandoned virtually all other work and even secluded himself on its site and resided in its workshop. In his 75th year, while on his way to vespers, he was struck down by a trolley car, and he died from the injuries.

In his drawings and models for the uncompleted church of the Holy Family (only one transept with one of its four towers was finished at his death), he equilibrated the cathedral-Gothic style beyond recognition into a complexly symbolic forest of helicoidal piers, hyperboloid vaults and sidewalls, and a hyperbolic paraboloid roof that boggle the mind and outdo the bizarre concrete shells built throughout the world in the 1960s by engineers and architects inspired by Gaudí. Apart from this and a similar, often uncritical, admiration for Gaudí by Surrealist and Abstract Expressionist painters and sculptors, Gaudí's influence was quite local, represented mainly by a few devotees of his equilibrated structure. He was ignored during the 1920s and '30s, when the International Style was the dominant architectural mode. By the 1960s, however, he came to be revered by professionals and laymen alike for the boundless and tenacious imagination that he used to attack each design challenge with which he was presented.

**Assessment.** The architectural work of Gaudí is remarkable for its range of forms, textures, and polychromy and for the free, expressive way in which these elements of his art seem to be composed. The complex geometries of a Gaudí building so coincide with its architectural structure that the whole, including its surface, gives the appearance of being a natural object in complete conformity with nature's laws. Such a sense of total unity also

informed the life of Gaudí; his personal and professional lives were one, and his collected comments about the art of building are essentially aphorisms about the art of living. He was totally dedicated to architecture, which for him was a totality of many arts.

(G.R.Co.)

**BIBLIOGRAPHY.** Critical works examining his career and architecture include Enrique Casanelles, *Antonio Gaudí: A Reappraisal* (1967), a collection of critical essays; George R. Collins, *Antonio Gaudí* (1960), with a chronology and annotated bibliography; George R. Collins and Juan Bassegoda Nonell, *The Designs and Drawings of Antonio Gaudí* (1983), with 70 plates; *Gaudí, the Visionary* (1971, reissued 1989), with essays by Salvador Dalí, Robert Descharnes, and Fransesc Pujols, and photos by Clovis Prévost—strong on anecdote and on Gaudí as a sculptor; César Martinell, *Gaudí: His Life, His Theories, His Work* (1975), an encyclopaedic work summarizing the author's many publications; James Johnson Sweeney and Josep Lluís Sert, *Antoni Gaudí*, rev. ed. (1970); and Ignasi de Solà-Morales, *Gaudí* (1983). Another aspect of Gaudí's work is presented in Riccardo Dalisi, *Gaudí Furniture* (also published as *Gaudí: Furniture and Objects*, 1980).

**Gaudier-Brzeska, Henri**, original name HENRI GAUDIER (b. Oct. 4, 1891, Saint Jean-de-Braye, Fr.—d. June 5, 1915, Neuville-Saint-Vaast). French artist, one of the earliest abstract sculptors and an outstanding exponent of the Vorticist movement; he was instrumental in introducing modern art to England during the early years of the 20th century.

"Crouching Figure," marble by Henri Gaudier-Brzeska, c. 1914; in the Walker Art Center, Minneapolis, Minn.

Collection Walker Art Center, Minneapolis, Minn

Gaudier did not take up sculpture until 1910, after he had completed his artistic training at Orléans. The following year, he met Sophie Brzeska, who remained his devoted companion, and added her last name to his. The next year, he moved to London, where the poet Ezra Pound became his patron and propagandist; the writer and painter Wyndham Lewis drew him into the Vorticist movement just before World War I. The early carvings of Sir Jacob Epstein affected him, but he showed original attitudes toward form and content that reflected a deep understanding of the French avant-garde movement called Cubism, ultimately moving beyond it into pure abstraction.

Gaudier-Brzeska was killed in combat in World War I. The premature death of this magnetic prodigy spawned a legend of unfulfilled genius.

**Gaudin, Martin-Michel-Charles, DUC (duke) DE GAËTE** (b. Jan. 19, 1756, Saint-Denis, Fr.—d. Nov. 5, 1841, Gennevilliers). French finance minister throughout the French Consulate and the First Empire (1799–1814) and founder of the Bank of France (1800).

From 1773 Gaudin worked in those bureaux of the Contrôle Générale des Finances that handled the collection of taxes, and he eventually rose to be a head of the tax department. In 1791, during the French Revolution, he

was made a member of the commission in charge of the national treasury, but he resigned in 1795. Although offered the Ministry of Finance by the Directory, Gaudin twice refused (in 1795 and July 1799), accepting the post only on Nov. 10, 1799, after Napoleon Bonaparte's coup d'état.

As the minister in charge of tax collections, Gaudin worked hard to preserve the framework of the ancien régime's financial institutions while trying to make them more efficient and to adopt some of the innovations introduced by the Revolution. He created a body of permanent officials to assess and levy direct taxes, and he reimposed certain major indirect taxes in 1804. Gaudin also proposed a fairer distribution of the land tax, and in 1807 he helped to introduce the cadastre, a survey and official register of all the land in France for taxing purposes (authorized in 1791 but not enforced). Gaudin was an honest and methodical financial administrator, and for his conscientious efforts, Napoleon made him Duke de Gaëte (Gaeta) in 1809.

Later Gaudin served as a moderate deputy for Aisne in the Chambre Intraçable (1815–16) and again in the succeeding Chamber of Deputies (1816–18). He then served as governor of the Bank of France (1820–34). His *Mémoires, souvenirs, opinions et écrits* (1826–34) was published in three volumes. A new edition appeared in 1926.

**Gaugamela, Battle of**, also called BATTLE OF ARBELA (Oct. 1, 331 BC), clash between the forces of Alexander the Great of Macedonia and Darius III of Persia that decided the fate of the Persian empire. Attempting to stop Alexander's incursion into the Persian empire, Darius prepared a battleground on the Plain of Gaugamela, near Arbela (present-day Irbil in northern Iraq), and posted his troops to await Alexander's advance. Darius had the terrain of the prospective battlefield smoothed level so that his many chariots could operate with maximum effectiveness against the Macedonians. His total forces greatly outnumbered those of Alexander, whose forces amounted to about 40,000 infantry and 7,000 cavalry.

Alexander's well-trained army faced Darius' massive battle line and organized for attack, charging the left of the Persians' line with archers, javelin throwers, and cavalry, while defending against Darius' outflanking cavalry with reserve flank guards. During the combat, so much of Darius' cavalry on his left flank were drawn into the battle that they left the Persian infantry in the centre of the battle line exposed. Alexander and his personal cavalry immediately wheeled half left and penetrated this gap and then wheeled again to attack the Persians' flank and rear. At this Darius took flight, and panic spread through his entire army, which began a headlong retreat while being cut down by the pursuing Greeks. The Macedonian victory spelled the end of the Persian empire founded by Cyrus II the Great and left Alexander the master of southwest Asia.

*A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume*

**gauge**, also spelled GAGE, in manufacturing and engineering, a device used to determine, either directly or indirectly, whether a dimension is larger or smaller than another dimension that is used as a reference standard. Some devices termed gauges may actually measure the size of the object to be gauged, but most gauges merely indicate whether the dimensions of the test object are sufficiently close to those of the standard; *i.e.*, whether they are in the range between set limits, known as the tolerance, for a particular object. Gauges may operate mechanically or electrically.

Gauges are usually regarded as either fixed-type or deviation-type instruments. Fixed-type gauges are used to indicate whether a given dimension is larger or smaller than the standard. They may be of hard steel, soft steel, or glass. Sometimes chrome plating or tungsten-carbide coatings are used to prevent wear.

Plug, ring, snap, and limit gauges are fixed gauges usually made to satisfy special requirements. To check the accuracy of a hole, a cylindrical bar (plug gauge) with highly finished ends of different diameters is used. If the hole size is correct within tolerable limits, the small end (marked "go") will enter the hole, while the large end ("not go") will not. Ring gauges for checking the dimensions of cylindrical parts also utilize the tolerance principle, with "go" and "not go" sections. A snap gauge is formed like the letter C, with outer "go" and inner "not go" jaws, and is used to check diameters, lengths, and thicknesses.

Flush-pin gauges have one moving part and are used to gauge the depth of shoulders or holes. Form gauges are used to check the profile of objects; two of the most common types are radius gauges, which are packs of blades with both concave and convex circular profiles that are used to check the radii of grooves and corners, and screw-thread pitch gauges, which are blades with triangular serrations spaced to correspond with various pitches, or numbers of threads per inch or per centimetre.

Gauge blocks, also known as Johansson blocks, after their inventor, came into significant industrial use during World War I. They are small steel blocks, usually rectangular, with two exceptionally flat surfaces parallel to each other and a specified distance apart. They are sold as sets of blocks that can be wrung together in increments of ten-thousandths of an inch to gauge almost any linear dimension. Angle-gauge blocks can be put together to measure angles.

Deviation-type gauges indicate the amount by which the object being gauged deviates from the standard. This deviation is usually shown in units of measurement, but some gauges show only whether the deviation is within a certain range. They include dial indicators, in which movement of a gauging spindle deflects a pointer on a graduated dial; wiggler indicators, which are used by machinists to centre or align work in machine tools; comparators, or visual gauges; and air gauges, which are used to gauge holes of various types. Very precise measurements may also be obtained by the use of light-wave interference, but the instruments that do so are referred to as interferometers.

**gauge**, also called **RAILWAY GAUGE**, in railroad transportation, the width between the inside faces of running rails. Because the cost of construction and operation of a rail line is greater or less depending on the gauge, much controversy has surrounded decisions in respect to it, and a proliferation of gauges has developed throughout the world. A narrow gauge has, in addition to cost advantages, a capability for sharper curvature; among its disadvantages are reduced lateral stability and consequent loss of operating speed.

About three-fifths of the rail trackage in the world is the so-called standard gauge of 4 feet 8.5 inches (1.4 m), which originated with George Stephenson's pioneer Liverpool & Manchester line in 1829. It was exported from Britain to Europe and the United States with the export of British locomotives built to it. Among notable deviations are Russia's 5-foot (1.5-metre) gauge, Spain's 5-foot 6-inch (1.7-metre) gauge, and Japan's 3-foot 6-inch (1.1-metre) gauge. Several countries operate railroads on two different gauges; Pakistan operates on three; and Australia and India use four.

**gauge**, a measure of the bore of a shotgun. See bore.

**gauge theory**, class of quantum field theory, a mathematical theory involving both quantum mechanics and Einstein's special theory of relativity that is commonly used to describe subatomic particles and their associated wave fields. In a gauge theory there is a group of transformations of the field variables (gauge transformations) that leaves the basic physics of the quantum field unchanged. This condition, called gauge invariance, gives the theory a certain symmetry, which governs its equations. In short, the structure of the group of gauge transformations in a particular gauge theory entails general restrictions on the way in which the field described by that theory can interact with other fields and elementary particles.

The classical theory of the electromagnetic field, proposed by the British physicist James Clerk Maxwell in 1864, is the prototype of gauge theories, though the concept of gauge transformation was not fully developed until the early 20th century by the German mathematician Hermann Weyl. In Maxwell's theory the basic field variables are the strengths of the electric and magnetic fields, which may be described in terms of auxiliary variables (e.g., the scalar and vector potentials). The gauge transformations in this theory consist of certain alterations in the values of those potentials that do not result in a change of the electric and magnetic fields. This gauge invariance is preserved in the modern theory of electromagnetism called quantum electrodynamics (*q.v.*), or QED. Modern work on gauge theories began with the attempt of the American physicists Chen Ning Yang and Robert L. Mills (1954) to formulate a gauge theory of the strong interaction. The group of gauge transformations in this theory dealt with the isospin (*q.v.*) of strongly interacting particles. In the late 1960s Steven Weinberg, Sheldon Glashow, and Abdus Salam developed a gauge theory that treats electromagnetic and weak interactions in a unified manner. This theory, now commonly called the electroweak theory, has had notable success and is widely accepted. During the mid-1970s much work was done toward developing quantum chromodynamics (QCD), a gauge theory of the interactions between quarks (see quark). For various theoretical reasons, the concept of gauge invariance seems fundamental, and many physicists believe that the final unification of the fundamental interactions (i.e., gravitational, electromagnetic, strong, and weak) will be achieved by a gauge theory. See also quantum field theory.

**gauging station**, site on a stream, canal, lake, or reservoir where systematic observations of gauge height (water level) or discharge are obtained. From the continuous records obtained at these stations, hydrologists make predictions and decisions concerning water level, flood activity and control, navigation, and the like. Among the measuring devices used are a staff gauge, which is a graduated scale anchored in the water and read by observing the level of the water surface in contact with it; and a recording gauge, which continuously monitors water level, sensed by a probe or a float and recorded by a pen or printer on a moving sheet of paper.

**Gauguin, (Eugène-Henri-) Paul** (b. June 7, 1848, Paris, Fr.—d. May 8, 1903, Atuona, Hiva Oa, Marquesas Islands, French Polynesia), one of the leading French painters of the Postimpressionist period, whose development of a conceptual method of representation was a decisive step for 20th-century art. After spending a short period with Vincent van Gogh in Arles (1888), Gauguin increasingly abandoned imitative art for expressiveness through colour. From 1891 he lived and worked in Tahiti and elsewhere in the South Pacific. His masterpieces include the early "Vision After the Sermon" (1888) and "Where

Do We Come From? What Are We? Where Are We Going?" (1897–98).

**Early years.** Gauguin was the son of a journalist from Orléans and of a mother who was half French and half Peruvian Creole. After Napoleon III's coup d'état, the Gauguin family moved in 1851 to Lima, and four years later Paul and his mother returned to Orléans. At the age of 17 he went to sea and for six years sailed about the world in freighters or men-of-war. In 1871 he joined the stockbroking firm of Bertin in Paris and in 1873 married a young Danish woman, Mette Sophie Gad. His artistic leanings were first aroused by his guardian, Gustave Arosa, whose collection included pictures by Camille Corot, Eugène Delacroix, and Jean-François Millet, and by a fellow stockbroker, Émile Schuffenecker, with whom he started painting. Gauguin soon started going to a studio to draw from a model and receive artistic instruction. In 1876 his "Landscape at Viroflay" was accepted for the official annual exhibition, the Salon. He developed a taste for Impressionist painting and between 1876 and 1881 assembled an impressive group of paintings by Édouard Manet, Paul Cézanne, Camille Pissarro, Claude Monet, and Johan Barthold Jongkind.

"Self-Portrait," panel painting by Paul Gauguin, 1889; in the National Gallery of Art, Washington, D.C.

Gauguin met Pissarro in 1875–76 and began to work with him, struggling to master the techniques of drawing and painting. In 1880 he was invited to contribute to the fifth Impressionist exhibition, and this invitation was repeated in 1881 and 1882. He spent holidays painting with Pissarro and Cézanne and made visible progress, though his early works are often marred by clumsiness and have drab colouring. Gauguin thus became more and more absorbed by painting, and, in 1883, when the Paris stock exchange crashed and he lost his job, he decided "to paint every day." This was a decision that changed the course of his whole life. He had a wife and four children, but he had no income and no one would buy his paintings. In 1884 Gauguin and his family moved to Copenhagen, where his wife's parents proved unsympathetic, and his marriage broke up. He returned to Paris in 1885, determined to sacrifice everything for his artistic vocation. From then on he lived in penury and discomfort, his health was undermined by hardship, he became an outcast from the society to which he had belonged and could

never establish himself in any other, and he came to despise Europe and civilization.

In 1886 the expressive possibilities of colour were revealed to him in the pictures of Georges Seurat and Paul Signac, and he began to occupy himself with this aspect of painting at Pont-Aven, Brittany. Gauguin then had two decisive experiences: a meeting with van Gogh in Paris (1886) and a journey to Martinique (1887). The one brought him into contact with a passionate personality who had similar pictorial ideas and tried to involve him in working them out communally; this attempt came to a disastrous end after a few weeks at Arles in 1888. The other enabled Gauguin to discover for himself the brilliant colouring and sensuous delights of a tropical landscape and to experience the charm of a primitive community living the "natural" life. Gauguin decided to seek through painting an emotional release, in consequence of which he reacted against Impressionism. The key to his artistic attitude from 1888 on is to be found in these significant phrases:

Primitive art proceeds from the spirit and makes use of nature. The so-called refined art proceeds from sensuality and serves nature. Nature is the servant of the former and the mistress of the latter. She demeans man's spirit by allowing him to adore her. That is the way by which we have tumbled into the abominable error of naturalism.

*Break with Impressionism.* Gauguin therefore set out to redeem this error by "a reasoned and frank return to the beginning, that is to say to primitive art." A possible method for arriving at a new form of pictorial representation was suggested to him by Émile Bernard, a young artist well acquainted with stained glass, manuscripts, and folk art. He pointed out that in these arts reality was generally depicted in nonimitative terms and that the pictorial image was made up of areas of pure colour separated by heavy black outlines. Such was the origin of the style known as Cloisonnism, or Synthetism, which attained its most expressive possibilities in such paintings by Gauguin as "The Vision After the Sermon," "Bonjour Monsieur Gauguin!," and "The Yellow Christ" (1889).

When Gauguin broke with his Impressionistic past, he gave up using lines and colours to fool the eye into accepting the flat painted image as a re-creation of an actual scene and

"Two Tahitian Women," oil on canvas by Paul Gauguin, 1899; in the Metropolitan Museum of Art, New York City

The Metropolitan Museum of Art, New York City, gift of William Church Osborne, 1949 (49.58.1)

explored instead the capacity of these pictorial means to induce in a spectator a particular feeling. His forms became ideated and his colours suggestive abstractions. Maurice Denis, in *Théories* (1920), described a small painting executed by Paul Sérusier under Gauguin's direction in 1888; this landscape seemed to

have no form as a result of being synthetically represented in violet, vermilion, Veronese green and other pure colours. . . . "How does that tree appear to you?" Gauguin had asked. "It's green isn't it? All right, do it in green, the finest green on your palette. And that shadow? Isn't it blue? Well then, don't be frightened of making it as blue as possible." Thus [writes Denis] was presented to us for the first time, in a paradoxical but unforgettable manner, the fertile conception of a painting as "a flat surface covered with colours arranged in a certain order."

Gauguin indulged in "primitivism" because he could make a more easily intelligible image; his simple colour harmonies intensified this image; and, because he wanted his pictures to be pleasing to the eye, he aimed at a decorative effect. His purpose in all this was to express pictorially an "idea." It was as a result of this that he was acclaimed as a leading painter of the Symbolist movement. Gauguin's whole work is a protest against the soul-destroying materialism of bourgeois civilization. "Civilization that makes you suffer. Barbarism which is to me rejuvenation," he wrote (1891) to the Swedish playwright August Strindberg. So Gauguin installed himself in Brittany (Pont-Aven and Le Pouldu, 1889–90, 1894), Tahiti (1891–93, 1895–1901), and the Marquesas Islands (1901–03), where he could paint scenes of "natural" men and women.

Before 1891, Gauguin tended to flatten things deliberately, and his effect was often strained, but throughout the 1890s his primitivism became less aggressive as the influences of J.-A.-D. Ingres and Puvis de Chavannes led to increasingly rounded and modeled forms and a more sinuous line. This process can be followed in works such as "Nafea Faa Ipoipo" (1892; "When Shall We Be Married?"), "Nave Nave Mahana" (1896; "Holiday"), and "Golden Bodies" (1901). Simultaneously, Gauguin's images became more luxuriant and more naturally poetic as he developed his marvelously orchestrated tonal harmonies. His chief Tahitian work—"Where Do We Come From? What Are We? Where Are We Going?"—is an immense canvas painted in 1897–98. This is the consummate expression of much that he had painted in the previous six years, and the aura of dreamlike, poetic inconsequence which surrounds this semiphilosophical allegory of primitive life is most powerful.

From 1899 on, Gauguin became increasingly ill and was continually in pain; he was also involved in frequent rows with the governing authorities for siding with the natives against them. Yet despite melancholy, his last pictures still have serenity and hope.

*Influence.* In 1889–90 a group of young followers had gathered round him at Pont-Aven, including Sérusier, Charles Filiger, and Denis, who transmitted Gauguin's ideas to Édouard Vuillard and Pierre Bonnard. The Norwegian painter Edvard Munch owed much to Gauguin, as did the painters of the Fauve group—Henri Matisse in particular—who profited from his use of colour. Gauguin's primitivism and stylistic simplifications greatly affected the young Pablo Picasso and led to the aesthetic appreciation of black African art and hence to the evolution of Cubism. In Germany, too, Gauguin's influence was strong.

Gauguin was unique in his ability to hold a mysterious balance between idea, perception, and visual image. His pictures make their effect visually, not as a result of literary overtones. He was a great stylistic innovator, and, when he rejected the conception of a picture as a mirror image of an actual scene

and turned from an empirical to a conceptual method of pictorial representation, his influence was wide and long-ranging. (D.C.)

**BIBLIOGRAPHY.** Biographies of the artist include memoirs by his son, Pola Gauguin, *My Father, Paul Gauguin* (1937, reprinted 1988); Lawrence Hanson and Elisabeth Hanson, *The Noble Savage* (1954); René Huyghe, *Gauguin* (1959, reissued 1988); Henri Perruchot, *Gauguin* (1963); Bengt Danielsson, *Gauguin in the South Seas* (1965); Wayne Andersen, *Gauguin's Paradise Lost* (1971); Michel Hoog, *Paul Gauguin, Life and Work* (1987); Yann Le Pichon, *Gauguin: Life, Art, Inspiration* (1987); and Belinda Thomson, *Gauguin* (1987). Special aspects of Gauguin's work are studied in Christopher Gray, *Sculpture and Ceramics of Paul Gauguin* (1963, reissued 1980); Merete Bodelsen, *Gauguin's Ceramics: A Study in the Development of His Art* (1964); Władysława Jaworska, *Gauguin and the Pont-Aven School* (1972); H.R. Rookmaaker, *Synthetist Art Theories: Genesis and Nature of the Ideas on Art of Gauguin and His Circle* (1959, reissued with title *Gauguin and 19th-Century Art Theory*, 1972); Giuseppe Marchiori, *Gauguin* (1967, reissued 1989); and Marla Prather and Charles F. Stucky (eds.), *Gauguin: A Retrospective* (1987). Richard Brettell et al., *The Art of Paul Gauguin* (1988), an extensive exhibition catalog, reassesses Gauguin's place in the history of art and examines his complete works in painting, sculpture, and graphics.

**Gaul**, French GAULE, Latin GALLIA, the region inhabited by the ancient Gauls, comprising modern-day France and parts of Belgium, western Germany, and northern Italy. A Celtic race, the Gauls lived in an agricultural society divided into several tribes ruled by a landed class.

A brief treatment of Gaul follows. For full treatment, see MACROPAEDIA: France.

By the 5th century BC the Gauls had migrated south from the Rhine River valley to the Mediterranean coast. By the middle of the 4th century BC various Gallic tribes had established themselves across northern Italy from Milan to the Adriatic coast. The region of Italy occupied by the Gauls was called Cisalpine Gaul ("Gaul this side of the Alps") by the Romans. In 390 BC the Gauls seized and plundered the city of Rome. This humiliation helped to inspire the Romans' drive to conquer Gaul. The Cisalpine Gauls pushed into central Italy by 284. In a series of confrontations, the Romans defeated the tribe of the Insubres, took Milan, and established colonies in a buffer zone. In the Second Punic War, Hannibal of Carthage made an alliance with the Gallic Cenomani against the Romans; the Romans prevailed, however, and by 181 Rome had subjugated and colonized Cisalpine Gaul.

By the 2nd century BC, when the Romans extended their territory across the Alps into the south of France, they already controlled most of the commerce in that part of the Mediterranean. An alliance with the Aedui against the Allobroges and the Arverni brought the Romans control of the Rhône River valley after 120 BC. The Roman colony of Narbo Martius (Narbonne) was founded on the coast in 118, and the southern province became known as Gallia Narbonensis. An invasion by Germanic Cimbri and Teutones was defeated by Marius in 102, but 50 years later a new wave of invasions into Gaul, by the Helvetii from Switzerland and the Suevi from Germany, triggered Roman conquest of the rest of Gaul by Julius Caesar in 58–50 BC.

During 53–50 Caesar was engaged in suppressing a Gallic revolt led by Vercingetorix. He treated the Gauls generously, leaving their cities with a significant measure of autonomy, and thus secured the allegiance of Gallic soldiers in his civil wars against Pompey in 49–

45. A former religious centre of Gallic society, Lugdunum (Lyon) became the capital of Roman Gaul. The country was divided into four provinces: Narbonensis, Aquitania to the west and south of the Loire, Celtica (or Lugdunensis) in central France between the Loire and the Seine, and Belgica in the north and east. The Romans built towns and roads throughout Gaul and taxed the old Gallic landowning class while promoting the development of a middle class of merchants and tradesmen. The emperor Tiberius was obliged to suppress a rebellion of the nobles in AD 21, and the assimilation of the Gallic aristocracy was secured when the emperor Claudius (AD 41–54) made them eligible for seats in the Roman Senate and appointed them to governing posts in Gaul.

The next two centuries were marked by occasional revolts, by increasingly frequent invasions of Germanic tribes, against whom a line of *limes*, or fortifications, was erected from the middle Rhine to the upper Danube, and by the introduction of Christianity early in the 2nd century. During the reign of the emperor Marcus Aurelius (161–180), Germanic invaders crossed the *limes*. Frontier legions rebelled along the Rhine, spurring the civil wars that followed the death of the emperor Commodus in 192. An economic recession, marked by inflation and rising prices, hurt the towns and the small farmers.

In 260 Gaul, Spain, and Britain formed an independent Gallic empire, governed from Trier. The emperor Aurelian reclaimed Gaul for Rome in 273, but Germanic tribes devastated the country as far as Spain. Under Diocletian and his successors, reforms in defense and administration were instituted, but Gaul became a centre of the unrest that was fragmenting the empire. In the middle of the 4th century the tide of invasions swelled. By the 5th century the Visigoths had taken Aquitania, the Franks ruled Belgica, and the Burgundians dominated the Rhine. By the time the kingdom of the Frankish Merovingians arose, in the early 6th century, the Romans had lost control of Gaul.

In the end, Gaul proved to be an important repository of Roman culture. Gallic writers long kept the classical Roman literary tradition alive. Many of the amphitheatres, aqueducts, and other Roman works built in Gaul still stand.

**Gaul, Narbonese:** *see* Narbonensis.

**Gaulish language,** ancient Celtic language or languages spoken in western and central Europe and Asia Minor before about 500. Gaulish is attested by inscriptions from France and northern Italy and by names occurring in classical literature. Modern knowledge of the vocabulary and sounds of Gaulish is slight, and its exact relation to the Celtic languages of Britain and Ireland is not clear.

**Gaulle, Charles de,** in full CHARLES ANDRÉ JOSEPH MARIE DE GAULLE (b. Nov. 22, 1890, Lille, France—d. Nov. 9, 1970, Colombey-les-Deux-Églises), French soldier, writer, statesman, and architect of France's Fifth Republic.

**Education and early career.** De Gaulle was the second son of a Roman Catholic, patriotic and nationalist, upper-middle-class family. The family had produced historians and writers, and his father taught philosophy and literature; but as a boy de Gaulle already showed a passionate interest in military matters. He attended the Military Academy of Saint-Cyr and, in 1913, as a young second lieutenant, joined an infantry regiment commanded by Colonel Philippe Pétain.

De Gaulle was an intelligent, hardworking, and zealous young soldier and a military man of original mind, great self-assurance, and outstanding courage. In World War I he fought at Verdun, was three times wounded and three

De Gaulle, 1967

Bruno Barbey—Magnum

times mentioned in dispatches, and spent two years and eight months as a prisoner of war (during which time he made five unsuccessful attempts to escape). He was promoted by Marshal Pétain in 1925 to the Staff of the Conseil Supérieur de la Guerre (Supreme War Council). From 1927 to 1929 he served as a major in the army occupying the Rhineland. He also spent two years in the Middle East and then, having been promoted to lieutenant colonel, spent four years as a member of the secretariat of the Conseil Supérieur de la Défense Nationale (National Defense Council).

De Gaulle's writing career began with a study of the relation between the civil and military powers in Germany (*La Discorde chez l'ennemi*, 1924; "Discord Among the Enemy"), followed by lectures on his conception of leadership, *Le Fil de l'épée* (1932; *The Edge of the Sword*). A study on military theory, *Vers l'armée de métier* (1934; *The Army of the Future*), defended the idea of a small professional army, highly mechanized and mobile, in preference to the static theories exemplified by the Maginot Line, which was intended to protect France against German attack. His views made him unpopular with his military superiors, and the question of his right to publish under his name a historical study, *La France et son armée* (1938; *France and Her Army*), led to a dispute with Marshal Pétain.

**World War II.** At the outbreak of World War II, de Gaulle commanded a tank brigade attached to the French 5th Army. In May 1940, after assuming command as temporary brigadier general in the 4th Armoured Division—the rank that he retained for the rest of his life—he twice had the opportunity to apply his theories on tank warfare. He was mentioned as "an admirable, energetic, and courageous leader." On June 6 he entered the government of Paul Reynaud as undersecretary of state for defense and war, and he undertook several missions to England. When the Reynaud government was replaced 10 days later by that of Pétain, who intended to seek an armistice with the Germans, de Gaulle left for England. On June 18 in London he broadcast by radio his first appeal to his compatriots to continue the war under his leadership. On Aug. 2, 1940, a French military court tried and sentenced him to death.

De Gaulle had only a handful of haphazardly recruited political supporters and volunteers for what were to become the Free French Forces. He had no political status and was virtually unknown in both Britain and France. But he was totally devoted to France and had the strength of character (or obstinacy, as it often appeared to the British) to fight for French interests as he saw them with all the resources at his disposal.

To many on France's political left, a career officer who was a practicing Roman Catholic

was not an immediately acceptable political leader; while to many on the right he was a rebel against Pétain, a national hero and France's only field marshal. Radio broadcasts from London, the action of the Free French Forces, and the contacts of Resistance groups in France either with his own organization or with those of the British secret services brought national recognition of his leadership; but full recognition by his allies came only after the liberation of Paris in August 1944.

In London de Gaulle's relations with the British government were never easy, and de Gaulle often added to the strain, at times through his own misjudgment or touchiness. In 1943 he moved his headquarters to Algiers, where he became president of the French Committee of National Liberation, at first jointly with General Henri Giraud. De Gaulle's successful campaign to edge out Giraud gave the world proof of his skill in political maneuvering.

**Early political career.** On Sept. 9, 1944, de Gaulle and his shadow government returned from Algiers to Paris. There he headed two successive provisional governments but, on Jan. 20, 1946, abruptly resigned, apparently owing to his irritation with the political parties forming the coalition government.

In November 1946 the Fourth French Republic was declared, and until 1958 de Gaulle campaigned against what he considered an inadequate constitution. In 1947 he formed the Rally of the French People (*Rassemblement du Peuple Français*; RPF), a mass movement that for all intents and purposes became a political party during the elections of 1951, when it won 120 seats in the National Assembly. The movement expressed de Gaulle's hostility to the constitution, to the party system, and, in particular, to the Moscow-oriented French Communists. He became dissatisfied with the RPF, however, and in 1953 severed his connection with it. In 1955 it was disbanded.

The general made no public appearances in 1955–56 and retired to work on his memoirs: *L'Appel, 1940–1942* (1954; *The Call to Honour, 1940–1942*), *L'Unité, 1942–1944* (1956; *Unity, 1942–1944*), and *Le Salut, 1944–1946* (1959; *Salvation, 1944–1946*). The last volume was completed only after his return to power in 1958.

**Return to public life.** De Gaulle's compatriots were deeply divided on the question of his return to public life, for which an opportunity presented itself in May 1958, when the insurrection that had broken out in Algiers threatened to bring civil war to France. De Gaulle was cautious, for it was by no means certain that the French parliament would accept his return on satisfactory conditions. He affirmed his determination not to come to power by other than legal means, and there was never any evidence of his association with insurgent plans to bring him back; however, his carefully worded statements (on May 15, 19, and 27) certainly helped the insurgents. On June 1, three days after Pres. René Coty threatened to resign unless de Gaulle's return to power was accepted, de Gaulle presented himself before the National Assembly as a prime minister designate. On the following day he attended the parliamentary session (after he was duly "invested" as prime minister) that authorized him to reform the constitution and accorded him the special powers that he demanded.

On Dec. 21, 1958, de Gaulle was elected president of the republic. The powers given to the president in the new constitution, which had been approved by referendum on Sept. 28, 1958, and especially those providing for the use of the referendum and for presidential

rule during a state of emergency, reflected his firm conviction that a strong state required a leader with power to make decisions. To disarm the power of "the system of parties" in parliament, always potentially hostile to him, de Gaulle's tactics were first to obtain consent for presidential control of government policy and then to ensure its renewal through elections or referendums. He therefore undertook throughout his presidency what was virtually a continuous election campaign, in the form of provincial tours. He appeared on television several times a year. He relied as far as possible on ministers who were *compagnons*—those whose loyalties went all the way back to the wartime days.

De Gaulle retained the essential function of parliament in a democracy, namely, the right to criticize governments and to withdraw confidence in them. There were frequent complaints of pro-governmental bias on the radio, but these also had been common under pre-Gaullist regimes. Under a law of 1881 insults to the president of the republic constitute an offense, and, while there was certainly more recourse to this law during de Gaulle's presidency than under previous regimes, it presented no obstacle to political criticisms of Gaullist policies and Gaullist ministers in the press and by political parties. Indeed, those criticisms were continual and widespread.

De Gaulle's greatest challenge in his early years as president was to find a way to resolve the bloody and extraordinarily divisive Algerian War. France's influential left-wing intellectuals supported Algerian independence. The European residents of Algeria and their many supporters on the mainland, most of them politically conservative, wanted France to retain Algeria at all costs. The leaders of the Algerian National Liberation Front (FLN), meanwhile, were willing to discuss nothing short of full independence. De Gaulle began peace negotiations with the FLN, whereupon French military leaders in Algiers turned against him, forming a rebel faction known as the Secret Army Organization (OAS).

In April 1961 the OAS seized control of Algiers and threatened to take Paris as well. De Gaulle responded vigorously, using the emergency powers permitted by the constitution of the Fifth Republic. Most French citizens rallied to de Gaulle, and after a tense standoff, the OAS action fell apart, the bulk of the military having refused to side with the rebellious generals. The bloodletting, however, was not over. The OAS, now a full-fledged terrorist organization, undertook a wave of bombings and assassinations (including attempts on de Gaulle) that left some 12,000 victims. But the overwhelming majority of the population supported de Gaulle, allowing him to negotiate Algerian independence (1962) and defeat the OAS.

De Gaulle was now in a position to turn to other pressing matters. Beginning in 1962, he moved to strengthen the country's economy, planned the reorganization of the army, developed an independent nuclear deterrent, and provided for the constitutional transformation of the African overseas territories into 12 politically independent states. From mid-1962 onward, however, with the recognition of an independent Algerian state, he was no longer politically indispensable.

One lesson that de Gaulle had learned was that his personal position was stronger if he remained, at least in theory, above the political and party battle, as he had tried to do during the wartime and early postwar years. Before the elections of 1958, he had therefore forbidden his supporters to use his name, "even in the form of an adjective," in the title of any group or candidate. In 1962 he offered

the electors the choice between his resignation and acceptance of a constitutional amendment providing for the election of the president by universal suffrage. Under the original constitution, the president was to be chosen by an electoral college of some 80,000 members, mainly mayors and local leaders. The electors favoured the amendment overwhelmingly. During the parliamentary general election in November, the Gaullist party won an additional 64 seats, thus obtaining, with the support of some 30 conservative deputies, a majority in the National Assembly. From then on, de Gaulle was in a position to carry out, with public consent, the plans that he regarded as essential to restore France to the status of a great power.

As a statesman, de Gaulle fought his political battles like a military campaign, using all the devices that he had learned to transform France's postwar international position of weakness into one of strength and to overcome opposition to his plans at home. These devices have been often described by his fellow citizens: "egoism, pride, aloofness, guile," according to sociologist and historian Raymond Aron; "empiricism, intuition, flexibility of mind if not of soul," according to one of the most perceptive of his biographers, Jean Lacouture.

From 1962 until his reelection as president in 1965, de Gaulle used the European Economic Community (EEC; now part of the European Union) to serve French interests, especially agricultural interests. France's participation in the supranational North Atlantic Treaty Organization (NATO) was progressively withdrawn, because de Gaulle's policy for France was one of "national independence" and of international cooperation based only on agreements between nation-states. This was the main theme of his presidential campaign in 1965. On December 21 he was reelected, though only on the second ballot, after facing a surprisingly strong challenge from the Socialist François Mitterrand. On March 7, 1966, he announced France's withdrawal from the integrated military command of NATO, though not from the alliance.

De Gaulle had already begun a policy of "détente and cooperation" with countries behind the Iron Curtain by encouraging trade and cultural relations with the Soviet Union and the countries of eastern Europe and by recognizing the People's Republic of China in January 1964. As a solution for the Vietnam War, he advocated a policy of neutrality for all nations concerned based on a negotiated peace, of which a necessary preliminary was to be the withdrawal of all U.S. troops from Vietnam. These activities, together with visits to Canada, the Far East, and all of Latin America, formed part of a policy that aimed at increasing the influence of France, first in French-speaking countries or countries that shared some bond derived from a common attachment to Latin culture, then in Europe, and finally in the world, where he foresaw the gradual dissolution of the two great blocs.

Circumstances worked against his success. He felt obliged to take up attitudes that were generally interpreted as anti-American. His theory of "desatellization," the progressive loosening of the Soviet hold on the countries of eastern Europe, was brutally invalidated by the Soviet invasion of Czechoslovakia in 1968. Furthermore, as the political and economic crisis of May 1968 revealed, France had neither the internal cohesion nor the financial resources to play the role of leader in what de Gaulle called "Europe from the Atlantic to the Urals."

His strength had been in his appeal for unity against a common enemy—in 1940, Germany; in 1958, subversion and civil disorder. In the students' and workers' revolt of May 1968, the enemy was once again subversion

and civil disorder, but the rapid collapse of the revolt and the divisions within the left that it revealed made de Gaulle seem less indispensable than in the past. Solutions required the patient negotiation of a government rather than leadership by a man of destiny. A broadcast on May 30 brought a massive demonstration of support and a landslide Gaullist victory in the subsequent election, but the victory was for peace and normality rather than for the president and his policies.

When in April 1969 de Gaulle called once again for a referendum, it was not clear whether he really wanted to remain in power. The referendum, calling for the acceptance of regional reorganization and a reform of the Senate, was presented to voters, as other referenda had been, as a choice between acceptance of both measures (though the second was generally unpopular) and his resignation. The diplomatic methods that had been welcomed during his first term as assertions of France's claim to greatness now created much unease. His advocacy of neutrality on Vietnam in 1966 was widely interpreted as an expression of personal anti-Americanism. On his visit to Canada in 1967, he seemed actively to encourage French-Canadian separatism. His declarations of neutrality in the 1967 Arab-Israeli War seemed to show a pro-Arab bias. France had not formally withdrawn from NATO, and the so-called independent nuclear deterrent that he sought was neither independent nor within France's means. The question "After de Gaulle, who?" was answered by the president himself when he dismissed Georges Pompidou in 1968 after a record six years as prime minister. This left Pompidou free to present himself as a credible and acceptable successor to de Gaulle.

On April 28, 1969, following his defeat in the referendum, de Gaulle resigned and returned to Colombey-les-Deux-Églises to retire permanently and to resume writing his memoirs. There he died of a heart attack the following year. His aims and actions as president had drawn more exegesis and speculation than those of any other French statesman. (D.M.P./Ed.)

**BIBLIOGRAPHY.** De Gaulle's memoirs are published together as *The Complete War Memoirs of Charles de Gaulle* (1964, reissued 1998; originally published in French, 1954–59). Biographies include David Thomson, *Two Frenchmen: Pierre Laval and Charles de Gaulle* (1951, reprinted 1975), an excellent short study of de Gaulle's prewar military career and the war years; Brian Crozier, *De Gaulle* (1973, reprinted 1990); Jean Lacouture, *De Gaulle*, 2 vol. (1990–92; trans. from French rev. ed., 3 vol., 1984–86), a detailed study; and Charles Williams, *The Last Great Frenchman* (1993, reissued 1998). Specifics of de Gaulle's foreign relations during World War II are addressed in François Kersaudy, *Churchill and de Gaulle* (1981, reissued 1990); and Raoul Aglion, *Roosevelt and de Gaulle, Allies in Conflict: A Personal Memoir* (1988). De Gaulle's political and social views are examined in Philip G. Cerny, *The Politics of Grandeur: Ideological Aspects of de Gaulle's Foreign Policy* (1980); and Daniel J. Mahoney, *De Gaulle: Statesmanship, Grandeur, and Modern Democracy* (1996).

**Gaulli, Giovanni Battista** (Italian painter): see Baciccia.

**Gaullists** (French political party): see Rally for the Republic.

**Gaultheria**, genus of about 100 species of upright or prostrate evergreen shrubs, of the heath family (Ericaceae), occurring in North and South America, Asia, and Australia. The plants are distinguished by alternate, ovate leaves, white or pink flowers, and round fruit that contains numerous minute seeds. *G. shallon*, the salal or lemonleaf of florists, is a slender, diffuse shrub of the California redwood forests; it grows 0.3–1.8 metres (1–6 feet) tall and has dark-purple edible berries.

Salal (*Gaultheria shallon*)

A J Huxley

*G. procumbens*, commonly known as checkerberry, teaberry, or wintergreen (*q.v.*), is a creeping shrub with white, bell-shaped flowers, spicy red berries, and shiny, aromatic leaves. *G. hispida*, or creeping snowberry, is a mat-forming evergreen with small, pointed leaves that give a spicy odour when crushed.

**Gaultier, Denys**, also called GAULTIER LE JEUNE (the Younger) (b. 1597 or 1603, Marseille?—d. January 1672, Paris, France), celebrated lute virtuoso whose style influenced the French school of harpsichord music.

Gaultier came from a renowned family of lutenists that also included Jacques and Ennemond Gaultier. Little is known of his life except that he resided for many years in Paris. He was the last great representative of the Parisian school of lutenists prominent in the early and middle years of the Baroque era. His music explores the full range of the French style—graceful and subtle ornamentation, broken chords, skillful exploitation of the lute's resources to suggest polyphonic texture. These facets of the lute style were transferred to the keyboard in the compositions of Jacques Champion de Chambonnières and the later *clavecinistes*, as were also the characteristic arrangement of stylized dances into suites and the fanciful and descriptive titles given to the individual pieces. Gaultier's compositions include the *Pièces de luth* and a collection of 69 compositions arranged in suites, in each of the 12 modes, *La Rhétorique des dieux* (1664–72; "The Rhetoric of the Gods"). He was hugely popular in his own time, and much of his music was transcribed from lute tablature into staff notation so that it might reach the growing public of keyboard players. Gaultier also originated the *tombeau*, a small piece written to the memory of a great personage.

**Gaultier de Varennes et de la Vérendrye, Pierre** (French-Canadian explorer): *see* La Vérendrye, Pierre Gaultier de Varennes et de.

**Gaulus** (Malta): *see* Gozo.

**Gaunilo**, French GAUNILON (fl. 11th century), Benedictine monk of the Marmoutier Abbey near Tours, France, who opposed St. Anselm of Canterbury's ontological argument for God's existence.

Gaunilo's *Liber pro insipiente* ("In Defense of the Fool") was a critique of the rationality of Anselm's assertion that the concept of "that than which nothing greater can be thought" (*i.e.*, God) implies God's existence. Gaunilo argued by analogy, pointing out that one's concept of a "perfect island" does not imply that such a place exists. The title of his book was taken from Anselm's reference to the atheistic "fool" of the 14th Psalm.

**Gaunt, John of:** *see* John of Gaunt, duke of Lancaster.

**gaur** (*Bos gaurus*), one of several species of wild cattle, family Bovidae (order Artiodactyla). The gaur lives in small herds in the mountain forests of India, Southeast Asia, and the Malay Peninsula. Larger than any other wild cattle, it attains a shoulder height of 1.8 m (6 feet) or more. It is heavy-bodied and typically blue-eyed and has curving horns, a high ridge on the forepart of the back, and white

Gaurs (*Bos gaurus*)

J A Hancock—Photo Researchers

"stockings" on the legs. Bulls are dark brown or blackish, cows and young reddish brown. Greatly reduced in numbers, gaurs survive only in scattered herds in India, Myanmar (Burma), West Malaysia, and Thailand.

**Gaurāṅga** (Hindu mystic): *see* Caitanya.

**gauss**, unit of magnetic induction in the centimetre-gram-second system of physical units. One gauss corresponds to the magnetic flux density that will induce an electromotive force of one abvolt ( $10^8$  volt) in each linear centimetre of a wire moving laterally at one centimetre per second at right angles to a magnetic flux. One gauss corresponds to  $10^{-4}$  tesla (T), the International System Unit. The gauss is equal to 1 maxwell per square centimetre, or  $10^{-4}$  weber per square metre. Magnets are rated in gauss. The gauss was named for the German scientist Carl Friedrich Gauss.

Before 1932 the name was applied to the unit of magnetic-field strength now called the oersted, and it is sometimes still used in this sense (*e.g.*, the Earth may be said to have a magnetic-field strength of about one gauss).

**Gauss, Carl Friedrich**, original name JOHANN FRIEDRICH CARL GAUSS (b. April 30, 1777, Brunswick [Germany]—d. Feb. 23, 1855, Göttingen, Hanover), German mathematician who had a long career in the applications of mathematics to astronomy, geodesy, and physics.

A brief treatment of Carl Friedrich Gauss follows. For full treatment, *see* MACROPAEDIA: Gauss.

Gauss was a prodigy, particularly in mental computation. In secondary school he distinguished himself in ancient languages and mathematics, and he conceived almost all his fundamental mathematical discoveries by age 17. At 22 he obtained his doctorate from the university at Helmstedt; in his thesis he developed the concept of complex numbers and proved the fundamental theorem of algebra. Two years later he published his theory of numbers, one of the most brilliant achievements in the history of mathematics. In 1807 he became professor of astronomy and director of the observatory at the University of Göttingen, where he remained for the rest of his life.

Gauss provided a new way for calculating the orbits of asteroids and the theory of squares. He contributed theoretical studies of the size and shape of the Earth and introduced the Gaussian error curve. He was a pioneer in applying mathematics to gravitation, electricity, and magnetism and developed the related potential theory and real analysis.

**Gauss elimination**, in linear and multilinear algebra, a process for finding the solutions of

a system of simultaneous linear equations by first solving one of the equations for the first variable (in terms of all the others) and then substituting this expression into the remaining equations. The result is a new system in which the number of equations and variables is one less than in the original system. The same procedure is applied to the second variable and continued with the other variables until there remains one equation, in which the only unknown quantity is the last variable. Solving this equation makes it possible to solve either of two earlier equations in which the last two variables were unknown. This process is continued until all of the originally unknown variables have been evaluated.

**Gaussian distribution** (mathematics): *see* normal distribution.

**Gauss's law**, either of two statements describing electric and magnetic fluxes. Gauss's law for electricity states that the electric flux across any closed surface is proportional to the net electric charge enclosed by the surface. The law implies that isolated electric charges exist and that like charges repel one another while unlike charges attract. Gauss's law for magnetism states that the magnetic flux across any closed surface is zero; this law is consistent with the observation that isolated magnetic poles (monopoles) do not exist.

Mathematical formulations for these two laws—together with Ampère's law (concerning the magnetic effect of a changing electric field or current) and Faraday's law of induction (concerning the electric effect of a changing magnetic field)—are collected in a set that is known as Maxwell's equations (*q.v.*), which provide the foundation of unified electromagnetic theory.

**Gautama:** *see* Buddha.

**Gauteng**, province, northeastern South Africa. It consists of the cities of Pretoria, Johannesburg, Germiston, and Vereeniging and their surrounding metropolitan areas in the eastern part of the Witwatersrand region. Gauteng is the smallest South African province. It is bordered by the provinces of Limpopo on the north, Mpumalanga on the east, Free State on the south, and North-West on the west. Gauteng (called Pretoria-Witwatersrand-Vereeniging in 1994–95) was part of the former Transvaal (*q.v.*) province until 1994. The provincial capital is Johannesburg.

Gauteng lies on the great interior plateau of southern Africa (the Highveld) and stretches northward from the Vaal River. South of Pretoria there is rolling grassland, and to the north of the city is bushveld. The province's climate is warm and temperate, and rainfall averages 26 inches (650 mm) annually.

Blacks make up about three-fourths of the province's population; whites, about one-fifth. Several languages are spoken in the province; the most widely spoken are Zulu, Afrikaans, Sotho, and English.

Though the province is largely urbanized, some farming, market gardening, and dairy farming are practiced. Gauteng contains enormous concentrations of gold, mainly in the ridge of gold-bearing rock in the south known as the Witwatersrand, where Johannesburg is located. There are also large reserves of platinum, chromite, iron ore, and uranium in the Bushveld Basin to the north. The varied assemblage of mining, industrial, commercial, and financial activities arising from this vast mineral wealth have made Gauteng the economic hub of South Africa and its most densely populated province.

Pretoria is the administrative (executive) capital of South Africa. Johannesburg, the provincial capital, is one of South Africa's largest metropolitan areas and its leading industrial,

financial, and commercial centre. Johannesburg International Airport is the nation's main international airport. Four universities—those of South Africa, Pretoria, Witwatersrand, and Rand Afrikaans—are located in the province. Area 7,243 square miles (18,760 square km). Pop. (1993 est.) 6,847,000.

**Gauthey, Emiland-Marie** (b. Dec. 3, 1732, Châlon-sur-Saône, France—d. July 14, 1806, Paris), French engineer, best known for his construction of the Charolais Canal, or Canal du Centre, which united the Loire and Saône rivers in France, thus providing a water route from the Loire to the Rhône River.

Gauthey studied at the École des Ponts et Chaussées (School of Bridges and Highways) in Paris, then taught there while making important pioneering contributions to the study of building materials. About 1767 he drew up plans for a canal linking the Loire and the Rhône. Work began under his direction in 1783, and the project was completed nine years later. The work involved construction of locks and several bridges. He also directed the building of a church at Givry between 1773 and 1791 and restored the castle of Chagny (both in Saône-et-Loire *département*) in 1780.

**Gautier D'ARRAS** (d. 1185), author of early French romances. He lacked the skill and profundity of his contemporary, Chrétien de Troyes, but his work, emphasizing human action and its psychological foundations, exercised an important influence on the genre known as *roman d'aventure* ("romance of adventure").

An official of Philippe d'Alsace, Count of Flanders, Gautier is named in many charters between 1160 and 1185. His romance *Eracle*, a mythical life of the Byzantine emperor Heraclius, was begun in 1176–78 for Marie de Champagne and Thibaut V of Blois but was finished, perhaps in 1179–81, for the young Baldwin V of Hainaut. *Ille et Galeron*, a Breton romance, was written for Beatrix of Vienne, the wife of Frederick I Barbarossa.

**Gautier DE METZ**, also known as GAUTHIER DE MÉS EN LOHERAINS (fl. 13th century), French poet and priest who is usually credited with the authorship of a treatise about the universe, *L'Image du monde* (c. 1246; "The Mirror of the World"; also called *Mappemonde*), based on the medieval Latin text *Imago mundi* by Honorius Inklusus. Gautier's poem is one of several medieval "encyclopaedic" works that describes creation, geography, and astronomy with factual as well as imaginary passages. Monsters, treasures, and distant lands are discussed in the pseudoscientific poem, which was translated into many languages during the Middle Ages and was beautifully illustrated in many manuscripts.

**Gautier, Hubert** (b. Aug. 21, 1660, Nîmes, France—d. Sept. 27, 1737, Paris), French engineer and scientist, author of the first book on bridge building.

After beginning a career in medicine, Gautier turned first to mathematics and then to engineering and served for 28 years as the engineer of the province of Languedoc. He was named inspector of bridges and highways of the realm in 1716, the year after publication of his *Treatise on the Constructions of Roads in France*. His *Treatise on Bridges*, which appeared in 1716, remained the standard work on bridge building for some 70 years.

**Gautier, Léon**, in full ÉMILE-THÉODORE-LÉON GAUTIER (b. Aug. 8, 1832, Le Havre, France—d. Aug. 25, 1897, Paris), literary historian who revived an interest in early French literature with his translation and critical discussion of the *Chanson de Roland* (1872) and with his research on the chansons de geste.

In Paris in 1859, Gautier became keeper of the imperial archives and of the archives of the *département* of Haute-Marne. In 1871 he became professor of paleography at the École

Léon Gautier

des Chartres, the school in which he had been educated (1852–55). He was elected a member of the Académie des Inscriptions et Belles-Lettres in 1887 and became chief of the historical section of the national archives in 1893. His works include *Les Épopées françaises*, 3 vol. (1886–88; "The French Epics," 2nd ed., 5 vol., 1878–97, with a bibliography of chansons de geste).

**Gautier, Théophile**, byname LE BON THÉO (b. Aug. 31, 1811, Tarbes, France—d. Oct. 23, 1872, Neuilly-sur-Seine), poet, novelist, critic, and journalist whose influence was strongly felt in the period of changing sensibilities in French literature—from the early Romantic period to the aestheticism and naturalism of the end of the 19th century.

Théophile Gautier, portrait in black crayon by Jean-Baptiste Clésinger, 1853; in the National Museum of Versailles and the Trianons

Cliche Musees Nationaux, Paris

Gautier lived most of his life in Paris. At the Collège de Charlemagne he met Gérard de Nerval and began a lasting friendship. He studied painting but soon decided that his true vocation was poetry. Sympathetic to the Romantic movement, he took part in the cultural battle that ensued when Victor Hugo's play *Hernani* was first performed in Paris in 1830. He humorously recalled this period in *Histoire du romantisme* (1874; "History of Romanticism") and in *Portraits contemporains* (1874; "Contemporary Portraits"), in which he gave an excellent description of his friend Honoré de Balzac. He satirized his own extravagances, as well as those of other Romantics, in *Les Jeunes-France* (1833; "Young France"). *Les Grottesques* (1834–36) is about more obscure earlier writers whose individualism anticipated that of the Romantics.

Gautier's first poems appeared in 1830. *Albertus*, a long narrative about a young painter who falls into the hands of a sorcerer, was published in 1832. At this time he turned from

the doctrines of Romanticism and became an advocate of art for art's sake. The preface to *Albertus* and the novel *Mademoiselle de Maupin* (1835) express his views, which caused a considerable stir in literary circles by their disregard of conventional morality and insistence on the sovereignty of the beautiful. His pessimism and fear of death were expressed in the narrative poem *La Comédie de la mort* (1838; "The Comedy of Death").

In 1840 Gautier visited Spain; the colour of the land and people inspired some of his best poetry, in *España* (1845), and prose, in *Voyage en Espagne* (1845). After this trip he found traveling to be a welcome escape from the constant pressures of his journalistic work, which he pursued to support himself, two mistresses, and his three children, as well as his two sisters. From 1836 to 1855 he was a weekly contributor to *La Presse* and *Le Moniteur Universel*; in 1851, editor of *Revue de Paris*; in 1856, editor of *L'Artiste*. Besides this work he contributed to many other periodicals and papers. Gautier often bemoaned the conditions of his existence; he felt that journalism was draining off the creative energy that should have been reserved for poetry.

Traveling, especially in Greece, strengthened his theory of art, his admiration of classical forms. He felt that art should be impersonal, free from the obligation of teaching moral lessons. The aim of the artist is to concentrate on achieving perfection of form. He developed a technique in poetry that he called *transposition d'art* ("transposing art"), recording his exact impressions when experiencing a painting or other work of art. These poems, published in *Émaux et camées* (1852; "Enamels and Cameos"), are among his finest, and the book was a point of departure for the writers Théodore de Banville and Leconte de Lisle. Charles Baudelaire paid tribute to Gautier in the dedication of his verse collection *Les Fleurs du mal*.

Gautier's poetic and fantastic imagination is seen to advantage in his short fiction—e.g., the evocations of ancient Pompeii in *Arria Marcella* (1852) and the vampire story *La Mort amoureuse* (1857; "The Dead Lover"). His literary output was prodigious, but his art and dramatic criticism alone—partly reprinted in *Les Beaux-Arts en Europe* (1855) and in *Histoire de l'art dramatique en France depuis vingt-cinq ans*, 6 vol. (1858–59; "History of Drama in France for Twenty-Five Years")—would ensure his reputation. As a ballet critic he remains unrivaled. He also wrote plays and the popular ballet *Giselle*, written in collaboration with Vernoy de Saint-Georges.

Gautier was held in esteem by many of his contemporaries who were also prominent literary figures: Gustave Flaubert, Charles-Augustin Sainte-Beuve, the Goncourt brothers, Banville, and Baudelaire. In his last years he became the friend of the Princess Mathilde, who gave him a sinecure post as a librarian to ease his financial strain.

**BIBLIOGRAPHY.** Joanna Richardson, *Théophile Gautier: His Life & Times* (1958); Richard B. Grant, *Théophile Gautier* (1975); and P.E. Tennant, *Théophile Gautier* (1975).

**Gautsch von Frankenthurn, Paul, Baron** (Freiherr) (b. Feb. 26, 1851, Döbling, Austria—d. April 20, 1918, Vienna), statesman who served three times as Austrian prime minister.

A graduate of the University of Vienna, Gautsch von Frankenthurn entered the imperial Ministry of Education (1874) and served as Austrian minister of education in the cabinets of Eduard, Count von Taaffe (1885–93), and Kasimir, Count von Badeni (1895–97). With the fall of Badeni, he was appointed prime minister (November 1897), but the failure of his proposed reform of the Bohemian language laws prompted his resignation (March 1898).

After several years as president of the government accounting office, Gautsch von Frankenthurn was recalled to the post of prime minister (Jan. 1, 1905), but again his ministry foundered, this time because of suffrage reform (May 1906). He was recalled once more in June 1911, but his third ministry expired after a few months. Ever faithful to the imperial summons, he remained, until the death of the emperor Francis Joseph I, one of the most trusted servants of the crown.

**gauze**, light, open-weave fabric made of cotton when used for surgical dressings and of silk and other fibres when used for dress trimming. The name is derived from that of the Palestinian city of Gaza, where the fabric is thought to have originated. It is made either by a plain weave or by a leno weave.

Similar fabrics include cheesecloth, made of cotton, originally used as a wrapping for pressed cheese and now used in bookbinding, as reinforcing in paper where high strength is desired, and for dustcloths and the like; bunting, made of cotton or wool, dyed and used for flags and decorations; scrim, made of cotton and used for curtains; and tobacco cloth, used as shade covering for tobacco plants. The main differences between them are in the finishing (for example, cheesecloth that is bleached and stiffened may be called scrim) and in the quality of the fibre (tobacco cloth is commonly made of low-grade yarns).

Metal wires and plastic filaments are woven into gauzes and used as window screens and filters. *See also* crinoline.

**Gavarni, Paul**, pseudonym of GUILLAUME-SULPICE CHEVALIER (b. Jan. 13, 1804, Paris, France—d. Nov. 24, 1866, Paris), French lithographer and painter whose work lacks the power of his great contemporary Honoré Daumier but is enjoyable for its polished wit, cultured observation, and the panorama it presents of the life of his time. Unlike Daumier, he did no political caricatures.

About 1831 Gavarni began publishing his scenes of everyday contemporary life, and praise from writers such as Honoré de Balzac gained him popularity. In 1833 he began publication of the *Journal des gens du monde* ("Journal of High Society"), which failed after 18 numbers and was responsible for Gavarni's imprisonment for debt in 1835 for almost a year. From 1839 to 1846 he issued his famous series "Les Lorettes," "Les Débardeurs," and "Les Fourberies de femmes." After the death of his mother and his marriage, about 1845, his style changed, deepening in seriousness and subtlety. Enhanced by a deeper insight into human nature, Gavarni's compositions of this time ironically depict the grotesque sides of family life and generally bear the stamp of a bitter philosophy. In 1847 he left for London and spent his time in England observing the life of the poor and producing some of his most compelling work. After his return to Paris he devoted more time to watercolour and in 1851 met the Goncourt brothers, who had long been his admirers; their book *Gavarni: l'homme et l'oeuvre* ("Gavarni: The Man and the Work") appeared in 1873. Again Gavarni took up lithography and in the periodical *Paris* brought forth another of his great series, "Masques et visages." At the time of his death he was working in etching, lithography, and a new process, electric engraving. J. Arnelhaut and E. Bocher's *L'Oeuvre de Gavarni, catalogue raisonné* (1873) lists about 8,000 of the artist's pictures.

**Gavarnie**, mountain village and valley on the approach to the natural amphitheatre known as the Cirque de Gavarnie, in Hautes-Pyrénées département, Midi-Pyrénées région, southwestern France. Gavarnie lies in the central Pyrenees, on the French side of the Franco-Spanish frontier. The village, at an elevation of 4,452 feet (1,357 m) in the valley

of the Gave (torrent) de Pau, was a resting place in medieval times for pilgrims traveling to Santiago de Compostela in northwestern Spain, which is one of the chief shrines of Christendom.

The Cirque de Gavarnie seen from a trail in the valley of Gavarnie, France

F. Jatain—TOP

The Cirque de Gavarnie, about 2.5 miles (4 km) south of the village, is described by the 19th-century French writer Victor Hugo as "a mountain and a wall at the same time . . . the colosseum of nature." From its floor, glacially eroded rock walls rise to about 5,000 feet (1,500 m). It has three conspicuous terraces in which precipitous faces are succeeded upward by steep slopes of ice and snow. The Grande Cascade waterfall plunges about 1,400 feet (425 m) from the eastern side. Above the amphitheatre are the high mountain summits of the Franco-Spanish frontier ridge, rising to nearly 11,000 feet (3,350 m). Also conspicuous is the deep cleft known as the Brèche de Roland. Nearby is the Grotte Castcret, containing a frozen underground stream. Pop. (1990) 178.

**Gaveston, Piers**, EARL OF CORNWALL (b. c. 1284—d. June 19, 1312, near Warwick, Warwickshire, Eng.), favourite of the English king Edward II. The king's inordinate love for him made him rapacious and arrogant and led to his murder by jealous barons.

The son of a Gascon knight, he was brought up at the court of Edward I as foster brother and playmate for his son Edward, the future king. Strong, talented, and ambitious, Gaveston gained great influence over young Edward, and early in 1307 he was banished from England by the king; but he returned after the death of Edward I a few months later (July 1307) and at once became the chief adviser of Edward II. Made Earl of Cornwall, he received both lands and money from the king and added to his wealth and position by marrying Edward's niece, Margaret, daughter of Gilbert de Clare, Earl of Gloucester (d. 1295). He was regent of the kingdom during the king's short absence in France in 1308 and took a very prominent part at Edward's coronation in February of that year. These proceedings aroused the anger and jealousy of the barons, and their anger was diminished neither by Gaveston's superior skill at the tournament nor by his haughty and arrogant behaviour toward themselves. They demanded his banishment; and the king, forced to assent, sent

his favourite to Ireland as lieutenant, where he remained for about a year.

After his recall by Edward in July 1309 (an event sanctioned by some of the barons), Gaveston became more insolent than ever, and the old jealousies soon broke out afresh. In 1311 the king was forced to agree to the election of the "Ordainers," and the Ordinances that they drew up provided, among other things, for the perpetual banishment of his favourite. Gaveston then retired to Flanders but returned secretly to England at the end of 1311. Soon he was publicly restored by Edward, and the barons had taken up arms. Deserted by the king, Gaveston surrendered to Aymer de Valence, Earl of Pembroke, at Scarborough in May 1312 and was taken to Deddington in Oxfordshire, where he was seized by Guy de Beauchamp, Earl of Warwick. Conveyed to Warwick Castle, he was beheaded on Blacklow Hill near Warwick. His body was buried with great ceremony in 1315 at King's Langley, in Hertfordshire, on orders of the king.

**gavial**, also called GHARIAL (*Gavialis gangeticus*), long-snouted reptile that is related to alligators and crocodiles but classified as the sole species in the separate family Gavialidae (order Crocodylia). The gavial inhabits the rivers

Gavial (*Gavialis gangeticus*)

© GERRY ELLIS NATURE PHOTOGRAPHY

of northern India. Like other crocodylians, it is lizardlike and reproduces by means of hard-shelled eggs laid in nests built by the female. It is distinguished by its long, very slender, and sharp-toothed jaws, which it sweeps sideways in order to catch fish, its main prey. The gavial normally attains a length of about 4–5 m (12–15 feet). It does not attack humans but apparently does feed on corpses set afloat in funeral ceremonies on the Ganges River.

The false gavial (*Tomistoma schlegelii*) looks like a gavial but is placed with the crocodylians in the family Crocodylidae. It is found in Southeast Asia.

**Gävle**, town and port, capital of Gävleborg län (county), east-central Sweden, on an inlet

The 18th-century courthouse in Gävle, Swed.

T. Lundeberg—Ostman Agency

of the Gulf of Bothnia, northwest of Stockholm. Although first mentioned in documents in the 8th century, it was not chartered until 1446. Despite several devastating fires, it grew from a fishing village into the main centre and export city for Norrland and the northern part of the iron-producing Bergslagen region. Manufactures range from paper to leather goods and porcelain; there is also a shipbuilding yard. The town has a restored late-16th-century castle and an 18th-century courthouse. Nearby Furuviik is a popular resort, and south-east of the city, at Järsvta, is a Viking burial ground. Pop. (1984 est.) mun., 87,671.

**Gävleborg, län** (county), east-central Sweden, on the shores of the Gulf of Bothnia. It is composed of the traditional *landskap* (province) of Gästrikland, most of Hälsingland, and a small part of Dalarna. Although low and level along the coast, it rises inland toward a wooded highland. The rivers—Ljusnan, Voxnan, Jädraån, Gävleån, and Dalälven—are not suitable for navigation but are used to produce hydroelectric power. Agriculture is not of great importance, though grain and potatoes are grown, and there is some stock raising. Along the coast, particularly around Gävle, the capital, there is extensive industrial development; paper and textiles are manufactured, and lumbering and sawmilling are important. Sandviken, which has had a steel industry since 1860, is noted for its saws. Other principal cities are Söderhamn, Bollnäs, and Hudiksvall. Area 7,024 square miles (18,192 square km.) Pop. (1999 est.) 282,226.

**gavotte**, lively peasants' kissing dance that became fashionable at the 17th- and 18th-century courts of France and England. Supposedly originated by the natives of Gap (Gavots) in the southeastern French province of Dauphiné, the gavotte was danced in royal ballrooms as a round with skipping steps adapted from the branle. Couples concluded improvised duet performances by kissing their part-

"Gavotte," illustration by Randolph Caldecott from *Brettonfolk*

ners. Later the dance developed more formal figures, and flowers were exchanged instead of kisses. At the French court in the 18th century, the gavotte was at first stately and later more ornate; its slow walking steps were in  $\frac{4}{4}$  time, with upbeat on beats 3 and 4.

In a suite the gavotte appears among the optional subordinate movements called *galanteries*. Its three-part composition is written in  $\frac{3}{4}$  rhythm but retains the later two upbeats; its second section is a musette, a pastoral air in which a drone bass runs throughout.

**Gavrilo**, original name GAVRILO DOŽIČ, or DOŽITCH (b. May 17, 1881, Morača, Montenegro—d. May 7, 1950, Belgrade), patriarch of the Serbian Orthodox Church (1938–50), noted for his anti-Nazi stand and, later, for his limited accommodations with the Communists.

Gavrilo was educated at Prizren in Serbia and at Athens and Istanbul. In 1910 he be-

came bishop of Peć and in 1920 metropolitan of Crnagora and Primorje (Montenegro and the Littoral). Elected by 50 out of 59 votes in a secret ballot of bishops to the patriarchate of the Serbian Orthodox Church, vacant since the death of Patriarch Varnava on July 24, 1937, he was enthroned on Feb. 21, 1938.

Gavrilo was one of the instigators of the coup d'état of March 27, 1941, that overthrew the pro-Axis government. After Germany had invaded Yugoslavia that same year, Gavrilo remained in his country but was arrested, interned first at monasteries, and then sent to the concentration camp at Dachau. Liberated on April 30, 1945, by the U.S. Army, he lived for a time in Rome, returning to Belgrade in November 1946. In December 1946 Gavrilo spoke at an all-Slav congress in Belgrade. A year later he called on the Orthodox clergy to cooperate with the government but, nevertheless, later refused to recognize the League of Serbian Priests, sponsored by the Communist Party. In July 1948, accompanied by Metropolitan Josip of Skopje, Gavrilo was present at the congress of the Orthodox churches in Moscow, but he refused to recognize the patriarch of Moscow and All-Russia as head of all Orthodox churches.

**Gawain**, hero of Arthurian legend and romance. A nephew and loyal supporter of King Arthur, Gawain appeared in the earliest Arthurian literature as a model of knightly perfection, against whom all other knights were measured. In the 12th-century *Historia regum Britanniae*, by Geoffrey of Monmouth, Gawain (or Walgaisus) was Arthur's ambassador to Rome; his name (spelled "Galvagnus") is carved against one of the figures on the 12th-century archivolt of Modena cathedral in Italy. In the verse romances of Chrétien de Troyes in the 12th century, he was never a hero but always a leading character who displayed outstanding prowess, which was, however, surpassed by that of Lancelot (who was inspired by the power of courtly love) and by that of the Grail-winner Perceval (who received spiritual inspiration).

As the Grail theme began to emerge as an important element of Arthurian romance, in the great prose romances of the 13th century known as the Vulgate cycle, Gawain was no longer seen as the ideal knight. In the *Queste del Saint Graal*, especially, he was unable to perceive the spiritual significance of the Grail, refused to seek divine aid through the sacraments, relied on his own prowess, and failed utterly in the quest. This deterioration of character was even more marked in later romances, such as the prose *Tristan*, in which a number of episodes depict him as treacherous and brutal to women. These darker aspects of his character were transmitted to English-speaking readers in Sir Thomas Malory's late 15th-century prose work *Le Morte Darthur*.

In Middle English poetry, however, Gawain was generally regarded as a brave and loyal knight. Perhaps his most important single adventure was that described in a fine, anonymous 14th-century poem, *Sir Gawayne and the Grene Knight* (q.v.), which tells the much older story of a beheading challenge.

In several of the romances and in Malory, Gawain's strength waxed and waned with the sun, a characteristic that links him with Gwalchmei, the solar deity of Celtic mythology. See also Arthurian legend; Grail.

**Gawler**, town, South Australia, northeast of Adelaide. It lies at the confluence of the North and South Para rivers (which there form the Gawler River), at the western foot of the Mt. Lofty Ranges. Surveyed in 1839, it was named after George Gawler, governor and resident commissioner in South Australia (1838–41), and was proclaimed a municipality in 1857. A dormitory town for Adelaide 25 miles (40 km) south, it also serves as a marketing centre for wheat, fruits, sheep, dairy

products, wine grapes, and flowers. Industries include flour milling, wine making, and the manufacture of agricultural machinery, clothing, cement, and bricks. Roseworthy Agricultural College is 7 miles north, and Parra Wirra Recreational Park and Sandy Creek Conservation Park are nearby. Pop. (1996) 15,484.

**Gawler Ranges**, mountains and hills in South Australia, extending 100 miles (160 km) east-west across the northern part of Eyre Peninsula, south of Lake Gardner; in altitude they rise in the west to as high as 1,550 feet (475 m) in Mount Bluff. The ranges were first sighted by the European explorer Edward John Eyre in 1839 and named in honour of the local governor George Gawler. The semi-arid shrub vegetation that covers them allows only limited livestock raising, but the eastern sector, known as the Middleback Ranges, contains rich iron-ore deposits, mined since the early 20th century. The region includes Yantanabie Historic Reserve, site of an old Aboriginal quarry, and Yardea National Estate, site of picturesque columns of porphyry.

**Gay, Jean-Baptiste-Sylvère** (French statesman): see Martignac, Jean-Baptiste-Sylvère Gay, vicomte de.

**Gay, John** (b. June 30, 1685, Barnstaple, Devon, Eng.—d. Dec. 4, 1732, London), English poet and dramatist, chiefly remembered as the author of *The Beggar's Opera*, a work distinguished by good-humoured satire and technical assurance.

John Gay, oil painting by William Aikman; in the Scottish National Portrait Gallery, Edinburgh

By courtesy of the Scottish National Portrait Gallery, Edinburgh

A member of an ancient but impoverished Devonshire family, Gay was educated at the free grammar school in Barnstaple. He was apprenticed to a silk mercer in London but was released early from his indentures and, after a further short period in Devonshire, returned to London, where he lived most of his life. Among his early literary friends were Aaron Hill and Eustace Budgell, whom he helped in the production of *The British Apollo*, a question-and-answer journal of the day. Gay's journalistic interests are clearly seen in a pamphlet, *The Present State of Wit* (1711), a survey of periodical publications.

From 1712 to 1714 he was steward in the household of the Duchess of Monmouth, which gave him leisure and security to write. He had produced a burlesque of the Miltonic style, *Wine*, in 1708, and in 1713 his first important poem, *Rural Sports*, appeared. This is a descriptive and didactic work in two short books dealing with hunting and fishing but containing also descriptions of the countryside and meditations on the Horatian theme of retirement. His finest poem, *Trivia; or, The Art of Walking the Streets of London* (1716), displays an assured and precise craftsmanship in which rhythm and diction underline whatever facet of experience he is describing. A sophisticated lady crossing the street, for example:

Her shoe disdains the street: the lady fair  
With narrow step affects a limping air.

*The Shepherd's Week* (1714) is a series of

mock classical poems in pastoral setting; the *Fables* (two series, 1727 and 1738) are brief, octosyllabic illustrations of moral themes, often satirical in tone.

*The Beggar's Opera* was produced in London on Jan. 29, 1728, by the theatre manager John Rich at Lincoln's Inn Fields Theatre. It ran for 62 performances (not consecutive, but the longest run then known). A story of thieves and highwaymen, it was intended to mirror the moral degradation of society and, more particularly, to caricature the prime minister Sir Robert Walpole and his Whig administration. It also made fun of the prevailing fashion for Italian opera. The play was stageworthy, however, not so much because of its pungent satire but because of its effective situations and "singable" songs. The production of its sequel, *Polly*, was forbidden by the lord chamberlain (doubtless on Walpole's instructions); but the ban was an excellent advertisement for the piece, and subscriptions for copies of the printed edition made more than £1,000 profit for the author. (It was eventually produced in 1777, when it had a moderate success.) *The Beggar's Opera* was successfully transmitted into the 20th century by Bertholt Brecht and Kurt Weill as *Die Dreigroschenoper* (1928; *The Threepenny Opera*).

"Honest" John Gay lost most of his money through disastrous investment in South Sea stock, but he nonetheless left £6,000 when he died. He was buried in Westminster Abbey, next to the poet Geoffrey Chaucer, and his epitaph was written by Alexander Pope.

**Gay, Sophie**, in full MARIE-FRANÇOISE-SOPHIE NICHULT DE LAVALLETTE GAY (b. July 1, 1776, Paris, Fr.—d. March 5, 1852, Paris), French writer and grande dame who wrote romantic novels and plays about upper-class French society during the early 19th century.

The daughter of a bursar to the Count de Provence (later King Louis XVIII), she married twice, the second time to a financier named Gay. Her first published writings, in 1802, yielded a novel, *Laure d'Estell*, but she did little other writing for 11 years, during which she led a somewhat notorious life. Among her numerous later novels were *Léonie de Montbreuse* (1813), *Malheurs d'un amant heureux* (1818, 1823; "Misfortunes of a Happy Lover"), *Le Moqueur amoureux* (1830; "The Amorous Mocker"), *La Physiologie du Ridicule* (1833; "The Physiology of Ridicule"), and *Le Mari confident* (1849; "The Confident Husband"). Mme Gay also wrote for the theatre, both drama and comic operas, with words and music; the play *La Duchesse de Châteauroux* (1834) received great success.

During the reign of Louis-Philippe, Mme Gay's salon was one of the most fashionable in Paris.

**Gay-Lussac, Joseph-Louis** (b. Dec. 6, 1778, Saint-Léonard-de-Noblat, Fr.—d. May 9, 1850, Paris), French chemist and physicist, pioneer investigator of the behaviour of gases and of techniques of chemical analysis, and one of the founders of meteorology.

*Early investigations.* Gay-Lussac graduated from the new École Polytechnique in Paris in 1800. In 1801 he became an assistant to chemist Claude-Louis Berthollet, whose laboratory was located in Arcueil, near Paris. This village was the centre of a group of young scientists known as the Arcueil circle and guided by Berthollet and Pierre-Simon Laplace, both of whom enjoyed the patronage of Napoleon.

Gay-Lussac's first major investigation was a study of the thermal expansion of gases. In 1802 he showed that all gases expand by the same fraction of their volume for the same increase in temperature. The existence of this common thermal-expansion coefficient made it possible to define a new temperature scale, the significance of which was eventually established by Sir William Thomson (later Lord Kelvin).

In 1804 Gay-Lussac and Jean-Baptiste Biot

studied the effects of altitude on the Earth's magnetic field by ascending in a hydrogen balloon. Continuing the study on a solo flight, Gay-Lussac reached a height of 23,018 feet (7,016 m), an altitude record that was unbroken for half a century. His observations led him to conclude that both the Earth's magnetic intensity and the chemical composition of the atmosphere were constant up to the altitude he had reached.

Gay-Lussac, engraving by Ambroise Tardieu  
By courtesy of the Bibliothèque Nationale Paris

Other work, with the Prussian scientist Alexander von Humboldt, led in 1805 to a precise determination of the relative proportions with which hydrogen and oxygen combine to form water. Gay-Lussac emphasized that the proportion by volume rather than by weight should be studied, and the results justified his position: one volume of oxygen combines with two volumes of hydrogen in forming water.

*Gay-Lussac's law.* On Dec. 31, 1808, the year in which he was married, Gay-Lussac announced the law that now bears his name. By this time he had been elected a member of the Institute of France and appointed to a professorship in Paris. His chemical researches in collaboration with another French chemist, Louis-Jacques Thenard, led Gay-Lussac to conclude that "gases combine in very simple proportions" and that "the apparent contraction in volume which they experience on combination has also a simple relation to the volume of the gases, or at least to one of them." This relationship is known as the law of combining volumes and as Gay-Lussac's law.

Gay-Lussac pointed out that the simple regularities of his law were realized only for gases, for which matter behaves in the simplest and most universal manner. It is worth noting that the English chemist John Dalton's laws of definite and multiple proportions in chemical composition referred to combining weights and not to volumes. Italian physicist Amedeo Avogadro showed how the results of Dalton and Gay-Lussac could be reconciled.

*Other chemical researches.* The collaborative work that Gay-Lussac did with Thenard was prompted by Sir Humphry Davy's electrochemical research. After Davy isolated potassium and sodium, Gay-Lussac and Thenard were able to establish the properties of potassium. They anticipated Davy in discovering the element boron, which they named. Gay-Lussac and Davy independently studied the properties of iodine (named by Gay-Lussac) in 1813.

Gay-Lussac's studies of hydrogen chloride, hydrogen iodide, and hydrogen fluoride prepared the way for a new theory of the nature of acids, although Gay-Lussac himself did not formulate it. (It had been held several years earlier by Antoine Lavoisier that oxygen is a common constituent of all acids.)

Among Gay-Lussac's many other investiga-

tions were his analyses of vegetable and animal substances, his studies of the solubility of salts as a function of temperature, and his contributions to volumetric analysis. In 1832 he gave up his professorship of physics to accept the chair of chemistry at the National Museum of Natural History in Paris.

He was elected to the Chamber of Deputies in 1831, 1834, and 1837 and in 1839 accepted a peerage from Louis-Philippe, after having refused one that had been offered years earlier by Charles X.

**gay rights movement**, also called HOMOSEXUAL RIGHTS MOVEMENT, or GAY LIBERATION MOVEMENT, civil-rights movement that advocates equal rights for gay men, lesbians, bisexuals, and transsexuals; seeks to eliminate sodomy laws barring homosexual acts between consenting adults; and calls for an end to discrimination against gay men and lesbians in employment, credit lending, housing, public accommodations, and other areas of life.

Before the end of the 19th century there were scarcely any "movements" for gay rights. Once referred to as "the love that dare not speak its name" by Oscar Wilde's lover, Lord Alfred ("Bosie") Douglas, homosexuality was given voice in 1897 with the founding of the Scientific-Humanitarian Committee (Wissenschaftlich-humanitäres Komitee) in Berlin; it published emancipation literature, sponsored rallies, and campaigned for legal reform throughout Germany and in The Netherlands and Austria, developing some 25 local chapters by 1922. Its founder, Magnus Hirschfeld, helped sponsor the World League of Sexual Reform. In 1914 the British Society for the Study of Sex Psychology was founded by Edward Carpenter and Havelock Ellis for both promotional and educational purposes.

An increasing number of organizations were formed in the mid- to late-20th century. The Cultuur en Ontspannings Centrum ("Culture and Recreation Center"), or COC, was founded in 1946 in Amsterdam. In the United States, the first major male organization, founded in 1950-51, was the Mattachine Society (its name reputedly derived from a medieval French society of masked players, Société Mattachine, to represent the public "masking" of homosexuality), while the Daughters of Bilitis (named after the Sapphic love poems of Pierre Louÿs, *Chansons de Bilitis*), founded by Phyllis Lyon and Del Martin in San Francisco in 1955, was a leading group for women.

The beginning of militant gay activism can be dated to the early morning hours of June 28, 1969, when the Stonewall Inn, a gay bar in New York City's Greenwich Village, was raided by the police. Nearly 400 people joined a riot that lasted 45 minutes and resumed on succeeding nights. Gay-rights organizations proliferated in the United States in the succeeding years. "Stonewall" came to be commemorated annually in June by Gay and Lesbian Pride Week, not only in U.S. cities but in cities in several other countries.

The International Lesbian and Gay Association was founded in Coventry, Eng., in 1978. Now headquartered in Brussels, it lobbies for human rights and fights discrimination against lesbian, gay, bisexual, and transgendered persons.

From the mid-1980s the U.S. movement was preoccupied with the AIDS epidemic, which affected many homosexual males. Gay-rights activists worked to support AIDS patients, heighten awareness of the disease in the gay community, and obtain funding for AIDS research. On an international scale, activist issues include immigration laws, political asylum for homosexuals, parenting rights, and equality in employment. Some of the symbols

associated with homosexuality and the gay rights movement are the Greek letter lambda ( $\lambda$ ), the inverted triangle (in pink and other colours), and the rainbow flag.

**Gayā**, city, south-central Bihār state, north-eastern India. It lies along the Phalgu River, a tributary of the Ganges. With major rail, road, and air connections, Gayā is a major centre of commerce. The city lies near the junction of the Gangetic Plain and the Choṭa Nāgpur plateau and is notoriously hot in summer.

Gayā is a noted Hindu pilgrimage centre, visited by about 300,000 pilgrims annually. There are 45 sacred places between Pretsil hill (north) and Bodh Gayā (south), but most are in Gayā itself. The main shrine is the Vishnu temple built by the Marāṭhā princess Ahalyā Bāī in 1787. Others are the rocky, temple-covered hills of Ramsilla and Brahmajini, the latter identified with the Gayāśiṣa hill on which the Buddha preached. The village of Bodh Gayā, 6 miles (10 km) south of Gayā, is famous as the site of the Buddha's enlightenment. Gayā has several libraries and several colleges affiliated with Magadh University. It was constituted a municipality in 1865.

Farmers plowing near Gayā, Bihār state, India  
Mitt and Joan Mann—CAMERAMANNI INTERNATIONAL

In the surrounding region, grains, oilseeds, and sugarcane are grown with the aid of irrigation from the Son, Pūnpūn, Morhar, and Phalgu rivers and the Patna Canal system. Building stone and mica deposits are worked in the region. Pop. (2001) 385,432.

**gayal**, also called MITHAN (*Bos frontalis*), one of the species of true cattle, belonging to the subfamily Bovinae (order Artiodactyla) and found in northeastern India and Myanmar (Burma). Considered a domestic form of the gaur, the gayal has larger dewlaps and thicker horns that extend outward without curving. Bulls stand 1.5 m (5 feet) at the shoulder and are blackish with white leg markings that look like stockings and a tail tuft, while the slightly shorter cows and the young are more brown than black. Woodland dwellers, they browse rather than graze. The animals roam unattended through the forest by day and return of their own accord to the village of their owner at night. Traditionally, the gayal is never milked but is slaughtered for meat or exchanged in payment of bride-price.

**Gayley, James** (b. Oct. 11, 1855, Lock Haven, Pa., U.S.—d. Feb. 25, 1920, New York, N.Y.), American metallurgist, who invented a device to ensure uniform humidity in the air stream going into blast furnaces.

Gayley enjoyed a long career in a variety of positions with steel companies. He began as a chemist for the Crane Iron Company, in Pennsylvania, and by the age of 30 he had worked his way up to superintendent of blast furnaces at a Pennsylvania steel plant that later became Carnegie Steel Company. By 1901 he was first vice president of the newly formed United States Steel Corporation.

Throughout his career Gayley developed devices to improve the construction of blast furnaces and the quality of iron produced in them, the most important of which was a device (patented with improvements 1894–1911) to prevent water vapour in the air from entering the furnace with the air blast and absorbing heat; previously, such vapour (a particular problem in regions with hot, humid summers) had harmed the quality of the pig iron. Gayley's basic idea, although improved upon or varied by his successors, has remained in wide use. With the gains from his varied career, he endowed the Gayley Hall of Chemistry and Metallurgy at Lafayette College, Easton, Pa.

**gaylussite**, a carbonate mineral, hydrated sodium and calcium carbonate [formulated  $\text{Na}_2\text{Ca}(\text{CO}_3)_2 \cdot 5\text{H}_2\text{O}$ ], that precipitates from soda lakes. It has been identified in deposits at Lagunillas, Venezuela; in the eastern Gobi (desert), Mongolia; near Ragtown, Nev., U.S.; at Borax Lake, Mono Lake, and Searles Lake, Calif., U.S.; and at Independence Rock, Wyo., U.S. Gaylussite readily weathers to calcite. For detailed physical properties, see carbonate mineral (table).

**Gayōmart**, Avestan GAYŌ MARETAN ("Mortal Life"), in later Zoroastrian creation literature, the first man, and the progenitor of mankind. Gayōmart's spirit, with that of the primeval ox, lived for 3,000 years during the period in which creation was only spiritual. His mere existence immobilized Ahriman, the evil spirit who wanted to invade creation. Then Ahura Mazdā created Gayōmart incarnate—white and brilliant, shining like the sun—and put in him and the primeval ox, alone of all created things, a seed whose origin was in fire.

Ahura Mazdā gave Gayōmart the boon of sleep for respite from the onslaught of Ahriman. But after 30 years of attacks, Ahriman destroyed Gayōmart. His body became the Earth's metals and minerals. Gold was his seed, and from it sprung the human race.

**Gaza**, kingdom established in the highlands of the middle Sabi River in Mozambique in the 1830s by Soshangane, the Ndwandwe general who fled from Zululand after his defeat at the hands of Shaka during the Zulu-Nguni wars known as the Mfecane. Soshangane extended his control over the area between the Komati (Incomati) and the Zambezi rivers, incorporating the local Tsonga and Shona peoples into his Zulu-type state and reducing the Portuguese to tributary status. The kingdom lasted until 1897, when, weakened by internal tensions, it was overthrown by the Portuguese.

**Gaza**, Arabic GHAZZAH, Hebrew 'AZZA, city and principal urban centre of the Gaza Strip, southwestern Palestine. Formerly the administrative headquarters for the Israeli military forces that occupied the Gaza Strip, it came under Palestinian control in 2005.

Records exist of its continuous habitation for more than 3,000 years; the earliest is a reference by Pharaoh Thutmose III (18th dynasty; 15th century BC). It is also mentioned in the Tell el-Amarna tablets, the diplomatic and administrative records of ancient Egypt. After 300 years of Egyptian occupation, one of the Sea Peoples, the Peleset (Philistines), settled the city and surrounding area. Gaza became an important centre of the Philistine Pentapolis (league of five cities). There the biblical hero Samson perished while toppling the temple of the god Dagon. Because of its strategic position on the Via Maris, the ancient coastal road linking Egypt with Palestine and the lands beyond, Gaza knew little peace in antiquity; it fell, successively, to the Israelite king David and to the Assyrians, Egyptians, Babylonians, and Persians. Alexander the Great met stiff resistance there; he sold its inhabitants into slavery. Throughout its history it

was a prosperous trade centre; in Hellenistic and Roman times, the harbour, about 3 miles (5 km) from the city proper, was called Neapolis (Greek: "New City"). In AD 635 the Arabs took Gaza, and it became a Muslim city. Gaza has long been an important centre of Islāmic tradition and is the reputed site of the burial place of Hāshim ibn 'Abd Manāf, great-grandfather of the Prophet Muḥammad, and the birthplace of ash-Shāfi'ī (767–820), founder of the Shāfi'ite school of Muslim legal interpretation. The city declined during the Crusades and never regained its former importance. After Saladin (Shālah ad-Dīn) defeated the crusaders at the Battle of Haṭṭin (1187), Gaza reverted to Muslim control, passing to the Ottoman Turks in the 16th century. In World War I it was stoutly defended by Ottoman troops and was not taken by British forces until November 1917.

After the war Gaza became part of mandated Palestine; a small coastal port (fishing, lighterage) was operated on the coast. When the Palestine partition plan was promulgated by the United Nations (1947), Gaza was assigned to the Arab state. This state, however, was not set up, and Gaza was occupied in 1948 by Egyptians. At the time of the signing of the Israeli-Egyptian armistice (February 1949), Egypt held Gaza and its environs, a situation that resulted in creation of the Gaza Strip. Egypt did not annex the city and territory but administered it through a military governor. Gaza and its surroundings continue to be greatly overpopulated by Arab refugees from Palestine.

During the Sinai Campaign of November 1956, Gaza and environs were taken by Israeli troops, but international pressure soon forced Israel to withdraw. Reoccupied in the Six-Day War (June 1967), the city was under Israeli military administration until 1994, when a phased transfer of governmental authority to the Palestinians got under way. In 2005 Israel completed its withdrawal from the Gaza Strip, handing over control of the region to the Palestinians.

Long a prosperous citrus centre, Gaza also has extensive truck farms within the city limits. Dark pottery, food products, and finished textiles are manufactured, and the city has a long-standing textile industry.

Sites of interest include a mosaic floor at the harbour (6th century AD; Byzantine period), evidently of an early synagogue, showing King David playing the harp and dressed as the Greek hero Orpheus. Pop. (2005 est.) 479,400.

**Gaza Strip**, Arabic QIṬA' GHAZZAH, Hebrew REZU'AT 'AZZA, territory occupying 140 square miles (363 square km) along the Mediterranean Sea just northeast of the Sinai Peninsula. The Gaza Strip is unusual in being a densely settled area not recognized as a de jure part of any extant country.

After Ottoman Turkish rule there ended in World War I, the Gaza area became part of the League of Nations mandate of Palestine under British rule. Before the termination in 1948 of this mandate, the General Assembly of the United Nations in November 1947 accepted a plan for the Arab-Jewish partition of Palestine under which the town of Gaza and an area of surrounding territory were to be allotted to the Arabs. The British mandate ended on May 15, 1948, and on the same day the first Arab-Israeli War broke out and Egyptian forces entered Gaza town, which became the headquarters of the Egyptian expeditionary force in Palestine. As a result of heavy fighting in autumn 1948, the area around the town under Arab occupation was reduced in extent to a strip of territory 25 miles (40 km) long and 4–5 miles (6–8 km) wide, which became known as the Gaza Strip. Its boundaries were demarcated in the Egyptian-Israeli armistice agreement of Feb. 24, 1949.

The Gaza Strip was under Egyptian military

rule during the periods 1949–56 and 1957–67. The chief economic and social problem of the area from its creation was the presence of large numbers of Palestinian Arab refugees, living in extreme poverty in squalid camps. Not considering the area its territory, Egypt did not allow the refugees to become citizens or to migrate to Egypt proper or to other Arab countries where they might be integrated into the population. Israel, on the other hand, did not allow them to return to their former homes. The refugees were maintained largely through the aid of the United Nations Relief and Works Agency for Palestine Refugees in the Near East (UNRWA). Many of the younger refugees became fedayeen (Arab guerrillas operating against Israel); their attacks on the Israeli civil populace were one of the causes precipitating the Sinai campaign of 1956, when the strip was taken by Israel. The strip reverted to Egyptian control in 1957 following strong international pressures on Israel.

In the Six-Day War (June 1967) the area was retaken by Israel, whose military administered it until 1994. In December 1987 rioting and violent street clashes between Gaza's Palestinians and occupying Israeli troops marked the birth of the Palestinian *intifadah*, or uprising. In 1994 Israel began a phased transfer of governmental authority in the Gaza Strip to the newly established Palestinian Authority (PA) under the terms of the Israeli-PLO accords. By 1995 the PA, led by President Yāsir 'Arafāt, struggled with such problems as a stagnant economy and divided popular support while continuing to negotiate further Israeli withdrawals from the Gaza Strip and the West Bank.

Beginning in late 2000, a breakdown in negotiations between the PA and Israel was followed by a further, more extreme outbreak of violence, termed the second *intifadah*. In an effort to end the fighting, Israeli Prime Minister Ariel Sharon announced in late 2003 a plan that centred on withdrawing Israeli soldiers and settlers from the Gaza Strip. In September 2005 Israel completed the pullout from the territory, and control of the Gaza Strip was transferred to the PA, although Israel continued to patrol its borders and airspace.

Living conditions in the Gaza Strip are poor owing to its dense and rapidly increasing population; inadequate water, sewage, and electrical services; and extreme unemployment. Agriculture is the economic mainstay of the employed population; nearly three-fourths of the land area is under cultivation. The chief crop, citrus fruits, raised on irrigated lands, is exported to European and other countries under arrangement with Israel. Truck crops, wheat, and olives also are produced. Light industry and handicrafts are centred in Gaza, the chief city of the area. In times of peace as much as one-tenth of the Palestinian population travels daily to Israel (where they are not allowed to stay overnight) to work in menial jobs.

The first accurate census, conducted in September 1967, showed a population smaller than had previously been estimated by the UNRWA or by Egypt, with nearly half of the people living in refugee camps. Pop. (2004 est.) 1,414,000.

**Gazankulu**, also called MACHANGANALAND, or MATSHANGANA-TSONGA, former nonindependent black state, northeastern Transvaal, South Africa, designated for the Shangaan and Tsonga people. It was made up of four detached portions of low veld, two of which adjoined Kruger National Park. The Tsonga people, the traditional inhabitants of the area, were joined by 19th-century Shangaan migrants from what is now Mozambique, culminating in a final wave of refugees after the Gaza kingdom (ruled by the Shangaan chief, Gungunhana) was conquered by the Portuguese in 1898.

Gazankulu had a territorial assembly from

1962 until 1972, when a legislative assembly was created. The state became officially self-governing in 1973 and held an election the same year. The capital was Giyani, in the northern detached portion of the state. When South Africa abolished apartheid in 1994, Gazankulu became part of Northern province (now Limpopo province).

**gazebo**, lookout or belvedere in the form of a turret, cupola, or garden house set on a height to give an extensive view. The name is an

Gazebo after a design by Antonio Petrini, near Würzburg, Ger.

Peter Coats

18th-century joke word combining "gaze" with the Latin suffix *ebo*, meaning "I shall." As a structured form, it is as old as garden history: it is the "viewing pavilion" of the Chinese or the summerhouse on the summit of a garden mount referred to by the 17th-century philosopher Francis Bacon.

The name should be applied not to any garden house but only to those with extensive views, perhaps only those with views in all directions. Few late 18th- or 19th-century "rustic" gazebos survive, but 17th-century turrets built up in an angle of the garden wall to give a prospect are not uncommon.

**gazelle**, any of the numerous antelopes of the genus *Gazella*, family Bovidae (order Artiodactyla). Graceful in build and small to medium in size, gazelles range in herds that usually contain about 5 to 10 individuals but may include up to several hundred.

Gazelles are found on open plains and semi-deserts from Mongolia westward to the Atlantic coast of North Africa and throughout eastern and central tropical Africa. Alert, attractive animals, gazelles stand from 60 to 90 cm (2 to 3 feet) at the shoulder. They are generally some shade of brown with white underparts and rump, and many have a horizontal dark band running along each side. A light stripe runs down each side of the face from above the eye to the muzzle, often with a dark streak below it; the forehead and the centre of the face between the stripes are generally darker than the body colour. The horns are short to medium in length, with numerous raised rings; they may be spreading, lyre-shaped, or backwardly curved and are always slightly upturned at the ends. The horns of the females are smaller and more slender than those of the males. In one species, the Persian, or goitered, gazelle (*G. subgutturosa*), the female is virtually hornless. The *Red Data Book* lists Pelzeln's gazelle (*G. pelzelni*) and the slender-horned gazelle (*G. leptoceros*) as critically endangered; a number of subspecies of other species are also considered endangered or seriously depleted in population.

There are about 12 species and more than 50 recognized forms of gazelles. Representatives include the following:

The Dama gazelle (*G. dama*) is the largest of all gazelles and inhabits North Africa. Its coat ranges from reddish brown with a white rump, underparts, and head in the western races, such as the critically endangered mhorr gazelle (*G. dama mhorr*), to white with reddish brown neck and shoulders in the eastern, red-necked gazelle (*G. dama ruficollis*). Its horns are bent sharply backward and then curve up and forward at the tips.

The Dorcas gazelle (*G. dorcas*) is a small North African species that is pale yellowish brown with a faint reddish brown stripe on each side. It has white and reddish brown stripes on its face, and its horns are ringed and lyre-shaped.

Grant's gazelle (*G. granti*) is a large gazelle of East Africa. It is pale brown with a dark nose spot and a distinct white stripe running from each horn to its muzzle. Its horns are long, strong, and curved and are exceptionally widespread in the subspecies Robert's gazelle (*G. granti robertsi*).

The Persian, or goitered, gazelle can be found from Turkey eastward to Mongolia. It is brownish in colour and possesses an indistinct darker band on each side. The female has rudimentary horns or none at all. The species is known as the goitered gazelle owing to the fact that the larynx of the male swells during the breeding season.

The red-fronted gazelle (*G. rufifrons*) is found from Senegal in the west to The Sudan in the east. It is reddish brown and has sides marked by a narrow black streak bordered below by a narrow, reddish brown band. Its horns are strong and slightly curved.

Thomson's gazelle (*Gazella thomsoni*)

E R Degginger

Thomson's gazelle (*G. thomsoni*), often called a Tommy, is the best-known and most common gazelle in East Africa. It is small and pale reddish brown in colour with a distinct black stripe along each side and has a black spot on its nose and white stripes on its face. Its horns are slightly curved.

Clark's gazelle (*Ammodorcas*) is the dibatag (*q.v.*); Waller's gazelle (*Litocranius*) is the gerenuk (*q.v.*).

**Gazelle Peninsula**, peninsula extending northeast from the island of New Britain, Bismarck Archipelago, Papua New Guinea, southwestern Pacific. It is about 50 miles (80 km) wide but tapers to 20 miles (32 km) at the isthmus joining it to the main part of the island. From coastal plains its surface rises as high as 7,999 feet (2,438 m) at Mount Sinewit of the central Baining Mountains. The area is actively volcanic (Mount Vulcan erupted in 1994, for example) and therefore highly fertile. The peninsula is the most populous portion of the island (particularly on the east), the Germans having established their centre

of settlement there late in the 19th century. Many copra and cocoa plantations along the coast ship their produce through the ports of Rabaul and Kokopo, both on Blanche Bay, and Keravat, on Ataliklikun Bay. These settlements are served by good secondary roads.

**Gazelle River** (The Sudan): *see* Baḥr al-Ghazāl.

**gazette**, originally, a newsheet containing an abstract of current events, the forerunner of the modern newspaper. The word is derived from the Italian *gazzetta*, a name given to informal news or gossip sheets first published in Venice in the mid-16th century. Similar sheets soon made their appearance in France and in England. The type of gazette originating from the private newsletter existed in England before the middle of the 16th century but was confined mainly to detailed accounts of diplomatic maneuvers. Upon the accession of Queen Elizabeth I, however, a far greater variety of such sheets began to appear. Aimed at a wide popular audience, they disseminated gossip, trivia, unofficial news accounts from nongovernmental sources, news of recent explorations, commercial advertisements, and the more sensational news items of the day—reports of lurid crimes, supposed miracles, witchcraft, and the like. The news collected in these sheets was contributed by volunteers, was frequently based on the accounts of anonymous witnesses, and was notorious for its inaccuracy. In the 17th century the term was increasingly applied to official government publications, such as the *Oxford Gazette* (founded 1665), which is considered to be England's first true newspaper. The *Oxford* later became the *London Gazette*, which is still published as a court journal, containing records of honours, official appointments, names of bankrupts, and public notices.

**Gaziantep**, city, south-central Turkey. It is situated near the Sacirsuyu, a tributary of the Euphrates, in limestone hills north of Aleppo, Syria.

The city was strategically situated near ancient trade routes, and recent excavations have unearthed fragments of pottery indicating settlement there in the early 4th millennium BC. Known as Hamtap in the Middle Ages, the city was an important stronghold guarding the Syrian routes and was captured by Turks in 1183. Thereafter it changed hands among various Turkmen and Arab dynasties and Mongol and Timurid invaders until its final absorption into the Ottoman Empire in the early 16th century. Called Ayıntab (Arabic 'Ayntāb: "Good Spring") under the Ottomans, it was occupied by the British in 1919 and by the French until 1921. By then it had become a centre of Turkish nationalist resistance to European occupation. Upon its return to Turkey in 1922, Mustafa Kemal (later called Atatürk), founder of the republic, renamed it in honour of its heroic stand (Turkish *gazi*, "champion of Islām"). Well-built, with stone houses, paved streets, and covered bazaars, Gaziantep is bordered by gardens, vineyards, and olive and nut groves.

Historical buildings include the ruined fortress built by the Byzantine emperor Justinian I (6th century AD) and mosques dating from the 11th and 16th centuries. A medieval theological college houses an archaeological museum that has an outstanding collection of Hittite seals unearthed in the region.

The surrounding area is delimited on the south by Syria and on the east by the Euphrates River. It is noted for its production of wines, *halvahs* and *baklava* (sweets), and *pekmez* (grape preserve); other products include pistachio nuts, aniseed, tobacco, and goatskin rugs. A region settled since antiquity, it includes the ancient sites of Duluk (ancient Doliche; site of the shrine of Jupiter Dolichenus); Kilis (the Assyrian Kilis); and the neo-Hittite city of Samal (Zincirli Hüyük; *q.v.*). Pop. (2000) city, 853,513.

**gazpacho**, cold soup of Spanish cuisine, especially that of Andalusia. It is an ancient dish mentioned in Greek and Roman literature, although two of the main ingredients of the modern version, tomatoes and green peppers, were brought to Spain from the New World only in the 16th century. Spanish cookbooks classify gazpacho as a salad.

The most frequently encountered gazpacho is an uncooked mixture of tomatoes, garlic, olive oil, water, vinegar, onions, cucumbers, and green peppers, thickened with bread crumbs. The word gazpacho is derived from the Arabic for "soaked bread." Gazpacho may be served with croutons, additional chopped vegetables, and chopped egg that the diners add to taste. The gazpacho of Málaga province in Andalusia is based on almonds and contains grapes.

**Gbaja**, also spelled GBAYA, or GBEYA (people): *see* Baya.

**Gbandi** (people): *see* Ngbandi.

**Gbarnga**, also called GBANGA, or GBANKA, city, north-central Liberia, West Africa, at the intersection of roads from Monrovia and northern Sierra Leone. A rural administrative and local trade centre, it has government and church secondary schools, several churches, and a mosque. Cuttington University College (Episcopalian) and Phebe Hospital are near Suakoko, 10 miles (16 km) west. Commercial poultry farming is a local activity, and eggs and chickens are marketed throughout the country. A rubber factory began operation in 1976 to semiprocess latex into crumb rubber. Pop. (2001 est.) 31,200.

**G.B.E.**, knight grand cross, or dame grand cross, of the British Empire, member of the highest class of a British order of knighthood. *See* British Empire, The Most Excellent Order of the.

**G.C.**, the George Cross, a British decoration for bravery. *See* George Cross.

**G.C.B.**, knight grand cross, or dame grand cross, of the Bath, member of the highest rank of knightly class in a British order of knighthood. *See* Bath, The Most Honourable Order of the.

**G.C.M.G.**, knight grand cross, or dame grand cross, of St. Michael and St. George, member of the highest rank of a British order of knighthood. *See* Saint Michael and Saint George, The Most Distinguished Order of.

**gcod** (Tibetan: "to cut off," or "to cut up"), esoteric Tibetan Buddhist rite that aims at "cutting off" the human ego and thus destroying the illusion of duality between samsara (the world of appearances and of death and rebirth) and nirvana.

The participant performs a dance alone, in an isolated spot, to his own accompaniment of a *thod-rnga* (an hourglass-shaped drum made of human skulls) and thigh-bone trumpet. The ritual consists of visualizing a number of deities to whom the participant symbolically offers himself as a sacrificial meal, imagining that the goddess Vajrayogini cuts off his head and uses it as a caldron to hold his dismembered body. The body is transformed into an offering to the assembled deities.

**G.C.V.O.**, knight grand cross, or dame grand cross, of the Royal Victorian Order, member of the highest rank of a British order of knighthood. *See* Royal Victorian Order.

**Gdańsk**, former (1975–98) *województwo* (province), north-central Poland, now part of Pomorskie (*q.v.*) province.

**Gdańsk**, German DANZIG, city, capital of Pomorskie *województwo* (province), north-central Poland, situated at the mouth of the Vistula River on the Baltic Sea.

First mentioned as a Polish city in 997 or 999, Gdańsk was part of the Polish diocese of Włocławek as noted in a papal bull of 1148. It was granted municipal autonomy in 1260 and developed as a trade centre. In 1308 the Teutonic Knights seized the city, which they held until 1466, when King Casimir IV of Poland regained the territory after a 13-year war. Granted local autonomy by the king in gratitude for its loyalty, Gdańsk expanded greatly, reaching its peak during the Renaissance as the most prosperous port on the Baltic. By 1754 it had the largest population (77,000) of any eastern European city and annual grain exports of more than 200,000 tons.

The Swedish wars of the 17th century halted the city's economic growth and began its decline. In 1772 Gdańsk was seized by Prussia, resulting in a rapid dissolution of port trade; and in 1793 it was incorporated as part of Prussia. Napoleon I granted it the privileges of a free city in 1807, but its territorial separation from Poland, because of the creation of a Prussian corridor to the sea, ruined its economy. Gdańsk appealed for reunification with Poland (1813–14); but when the Congress of Vienna instead partitioned Poland among Russia, Austria, and Prussia, the city was relegated to the province of West Prussia. Gdańsk became somewhat industrialized but failed to regain its stature as a great Baltic trading port.

Brama Wyzynna (High Gate), Gdańsk, built 1574  
By courtesy of CAF

From 1919 to 1939 it again had the status of a free city, under the Treaty of Versailles, with Poland having administrative governance over it. However, the Gdańsk legislative assembly, which was of German composition, tended to antagonize the Polish overseer whenever possible. Poland finally built another port on Polish territory at Gdynia, 10 miles (16 km) to the north. Gdynia grew rapidly, and Gdańsk also flourished. German control of the city increased as the German National Socialist (Nazi) Party won a majority of the assembly seats in the 1933 and 1935 elections. In 1938 Hitler demanded that Gdańsk be given to Germany; Poland's refusal was used by Germany as provocation for its attack on Poland on Sept. 1, 1939, which precipitated World War II.

Greatly damaged during the war, the city was returned to Poland in March 1945. Now fully reconstructed, it counts among its restored buildings St. Catherine's Church, sections of which date from the 14th century, and the medieval town hall. As Danzig it was the childhood home of the contemporary German writer Günter Grass, several of whose novels were set in the locality.

The city centre, known as Stare Miasto ("Old Town"), lies on the Motława, a tributary of the Vistula, 2 miles (3 km) inland. The city has two main port areas. The older Nowy Port ("New Port") is a major industrial centre for shipyards, metallurgical and chemical plants, timber mills, and food-processing facilities. The Polish maritime commission was first

Coal awaiting shipment at the Port of Gdańsk, Gdańsk, Pol.

© Steve Raymer/Corbis

begun there in 1568 to handle questions of defense and trade. The shipyards launched their first warship in 1572. In modern times, shipbuilding there has been an important source of foreign currency. Labour unrest in the Gdańsk shipyards in 1980 led to the creation of the Solidarity union. The newer Port Północny ("North Port") is Poland's largest maritime development project (its first stage completed in 1975); it handles coal exports and petroleum imports, much of the latter being processed at a nearby refinery. The city has an international airport and ferry connections to Sweden.

Gdańsk is an important cultural seat containing schools of medicine, engineering, and fine arts; a maritime centre; many fine churches, museums, theatres, and gardens; and a concert hall and an opera house. The University of Gdańsk was founded in 1970. Gdańsk is part of the Trójmiasto ("Three-City") urban area, comprising the towns of Gdańsk, Gdynia, and Sopot. Pop. (2002) 461,334.

**Gdańsk, Gulf of,** Gdańsk also spelled DANZIG, Polish ZATOKA GDAŃSKA, Russian GDANSKAYA BUKHTA, southern inlet of the Baltic Sea, bordered by Poland on the west, south, and southeast and by Kaliningrad *oblast* (province) of Russia on the east. The gulf extends 40 miles (64 km) from north to south and 60 miles (97 km) from east to west and reaches its maximum depth, more than 371 feet (113 m), in its northern section.

Within the gulf are Puck Bay on the west and the Vistula Lagoon (Zalew Wiślany) on the southeast and east. The gulf receives the Vistula River and, through the Vistula Lagoon, the Nogat, Pasleka, and Pregel rivers. Its ports include Gdańsk (Danzig), Gdynia, Sopot, Elbląg, Baltiysk, and Kaliningrad (Königsberg). Coastal activities include shipbuilding, fishing, and the resort trade.

**Gdynia,** city, Pomorskie województwo (province), north-central Poland. It lies along the Gulf of Gdańsk, just northwest of Gdańsk city.

First mentioned in 1253, Gdynia began as a fishing settlement. Major growth came only after World War I, when Gdynia was returned from Germany to Poland by the Treaty of Versailles. When the German-controlled legislative assembly in Gdańsk barred Poland's use of that city's port facilities, Poland chose Gdynia as the site for its new port. From 1924 to 1939 Gdynia was the major Baltic port,

surpassing Gdańsk and Szczecin. The Nazis destroyed the city and harbour during World War II, but Gdynia was quickly rebuilt after the war. It is the site of the "Paris Commune" shipyard, one of Europe's most modern. Gdynia is part of the Trójmiasto ("Three-City") urban area, along with Gdańsk and Sopot, and is the main passenger port for the three cities. It is a manufacturing centre and the home port of the Polish navy. Its chief exports are lumber, coal, and sugar, while iron ore and food products are the main imports. The city contains a naval museum and several maritime schools. Pop. (2002) 253,458.

not letter by letter

**Ge,** also spelled GÊ, South American Indian peoples who speak languages of the Macro-Ge group. They inhabit eastern and southern Brazil and part of northern Paraguay. The Ge peoples include the Northwestern Ge (Timbira, Northern and Southern Kayapó, and Suyá), the Central Ge (Xavante, Xerente, and Akroá), the Jeikó, the Kamakan, and the Southern Ge, or Kaingang (Guayaná, Coroado, and others). The Ge were originally hunters and gatherers who became semisedentary farmers, although most groups retained hunting and gathering as their primary source of food. Their number probably does not exceed 10,000.

The Ge social organization is unique among South American Indians in its complexity. Every village is divided into moieties (dual groupings), clans, and associations according to age, sex, and occupation. These are found in various forms and combinations in different places. Participation in almost all aspects of life—games, ceremonies, warfare, settlement patterns, marriage, handicrafts, names, friendships—is governed by the individual's relationships and associations. The diversity among Ge peoples makes for further complexity. Some groups are matrilineal (descent being reckoned in the female line), others patrilineal; some are exogamous (marriage being restricted to individuals outside one's clan, moiety, etc.), others endogamous; some are matrilocal (the married couple residing with the female's family), others patrilocal. The infusion of social structure into every aspect of Ge life results in a decentralization of authority, since collective activities tend to be performed by those groups most capable of or best suited for their realization.

The Ge peoples share certain general beliefs about the universe and practice similar forms of magic, although there are many specific differences. Their major deities are the sun and the moon. They have shamans to cure sickness; they believe in spirits inhabiting natural phenomena. Neither men nor women wear any dress except body ornamentation and elaborate painting.

**GE:** see General Electric Company.

**Ge Hong** (Taoist alchemist): see Ko Hung.

**Ge languages,** a group of about 10 South American Indian languages that extend through inland eastern Brazil as far as the Uruguayan border. Most linguists classify the Ge languages with a number of smaller groups (most of which were located closer to the Atlantic coast and are now extinct) in a Macro-Ge grouping.

**gear,** machine component consisting of a toothed wheel attached to a rotating shaft. Gears operate in pairs to transmit and modify rotary motion and torque (turning force) without slip, the teeth of one gear engaging the teeth on a mating gear. If the teeth on a pair of mating gears are arranged on circles, *i.e.*, if the gears are toothed wheels, the ratios of the rotary speeds and torques of the shafts are con-

stant. If the teeth are arranged on noncircular bodies the speed and torque ratios vary.

Most gears are circular. To transmit motion smoothly and with a nonvarying speed ratio at every instant, the contacting surfaces of gear teeth must be carefully shaped to a specific profile. If the smaller of a gear pair (the pinion) is on the driving shaft, the pair acts to reduce speed and to amplify torque; if the pinion is on the driven shaft the pair acts as a speed increaser and a torque reducer. If the

Pair of spur gears and a gear rack

driven gear has twice as many teeth as the pinion, for example, the torque of the driven gear is twice the pinion torque, whereas the pinion speed is twice the speed of the driven gear.

The shafts that gears connect must be relatively close, but they may have practically any spatial relationship with respect to one another; they may be parallel or nonparallel and intersecting or nonintersecting. For each of these arrangements of the shafts, gears having appropriate capabilities can be made. Parallel shafts can be connected by gears with teeth that are straight lengthwise and parallel to the shaft axes (spur gears) or by gears with twisted, screwlike teeth (helical gears). Intersecting shafts are connected by gears with tapered teeth arranged on truncated cones (bevel gears). Nonparallel, nonintersecting shafts are usually connected by a worm and gear. The worm resembles a screw, and the gear resembles a quarter section of a long nut that has been bent around a cylinder. Nonparallel shafts are most commonly arranged at right angles (90°).

Because it is basically a screw, a worm gear may have only one thread (tooth), whereas to maintain continuous contact with parallel shaft gears (spur and helical), the pinion must have at least five teeth. For this reason, to obtain a large speed ratio in a single gear pair, a worm and gear are well suited. If the shafts must be parallel, it may be necessary to use several gear pairs in series (a train) to obtain a large ratio. See also differential gear.

**Geb,** also called KEB, in ancient Egyptian religion, the god of the earth, the physical support of the world. Geb constituted, along with Nut (*q.v.*), his sister, the second generation in the

Geb falling away from intercourse with Nut, detail from the Papyrus of Tameniu; in the British Museum  
By courtesy of the Trustees of the British Museum

Ennead (group of nine gods) of Heliopolis. In Egyptian art Geb was often depicted lying by the feet of Shu, the air god, with Nut, the goddess of the sky, arched above them. Geb was usually portrayed as a man without any distinguishing characteristics, but at times he was represented with his head surmounted by a goose, the hieroglyph of his name. He was the third divine ruler among the gods; the human pharaohs claimed to be descended from him, and the royal throne was referred to as "the throne of Geb."

**Geber** (fl. 14th century), unknown author of several books that were among the most influential works on alchemy and metallurgy during the 14th and 15th centuries.

The name Geber, a Latinized form of Jābir, was adopted because of the great reputation of the 8th-century Arab alchemist Jābir ibn Ḥayyān. A number of Arabic scientific works credited to Jābir were translated into Latin during the 11th to 13th centuries. Thus, when an author who was probably a practicing Spanish alchemist began to write in about 1310, he adopted the westernized form of the name, Geber, to give added authority to his work, which nevertheless reflected 14th-century European alchemical practices rather than earlier Arab ones.

Four works by Geber are known: *Sunna perfectionis magisterii* (*The Sum of Perfection or the Perfect Magistry*, 1678), *Liber fornacum* (*Book of Furnaces*, 1678), *De investigatione perfectionis* (*The Investigation of Perfection*, 1678), and *De inventione veritatis* (*The Invention of Verity*, 1678). They are the clearest expression of alchemical theory and the most important set of laboratory directions to appear before the 16th century. Accordingly, they were widely read and extremely influential in a field where mysticism, secrecy, and obscurity were the usual rule.

Geber accepted most of the Arabic alchemical theories and spread them throughout western Europe. He assumed that all metals are composed of sulfur and mercury and gave detailed descriptions of metallic properties in those terms. He also explained the use of an elixir in transmuting base metals into gold.

Geber's rational approach, however, did much to give alchemy a firm and respectable position in Europe. His practical directions for laboratory procedures were so clear that it is obvious he was familiar with many chemical operations. He described the purification of chemical compounds, the preparation of acids (such as nitric and sulfuric), and the construction and use of laboratory apparatus, especially furnaces. Geber's works on chemistry were not equaled in their field until the 16th century with the appearance of the writings of the Italian chemist Vannoccio Biringuccio, the German mineralogist Georgius Agricola, and the German alchemist Lazarus Ercker.

**Gebhard OF DOLLNSTEIN-HIRSCHBERG** (pope): see Victor II.

**Gebrauchsmusik** (German: "music for use"), also called UTILITY MUSIC, music intended, by virtue of its simplicity of technique and style, primarily for performance by the talented amateur rather than the virtuoso. *Gebrauchsmusik* is, in fact, a modern reaction against the intellectual and technical complexities of much 19th- and 20th-century music, complexities that exalt the professional virtuoso and exclude the amateur from active participation. The purpose of *Gebrauchsmusik*, then, is to allow the nonprofessional musician to regain his role as an amateur music maker by providing him with a composition suitable for impromptu, nonvirtuoso performance.

In a sense, *Gebrauchsmusik* can be traced back to the simple keyboard and lute pieces

of the Renaissance, as well as to the chamber music of the Baroque and Classical eras. The term itself is a child of the 20th century, however, and most *Gebrauchsmusik* represents a species of neoclassicism (the use of old genres, but with contemporary techniques). The leading exponent of the *Gebrauchsmusik* movement was Paul Hindemith (1895–1963), who probably coined the term but later disavowed it. J.S. Bach's church music was cited as the earliest example, and later practitioners included Kurt Weill and Ernst Krenek.

**gecko**, also spelled GEKKO, any lizard of the harmless but noisy family Gekkonidae, which contains about 80 genera and about 750 species. Geckos are small, usually nocturnal reptiles with a soft skin, a short, stout body, large head, and weak limbs often equipped with suction-padded digits. Most species are 3 to 15 cm (1.2 to 6 inches) long, including tail length (about half the total). They have adapted to habitats ranging from deserts to

Diurnal gecko (*Phelsuma*)  
Anthony Bannister

jungles. Many species frequent human habitations, and most feed on insects.

Most geckos have feet modified for climbing. The pads of their long, flattened toes are covered with numerous tiny, hairlike processes that are forked at the end. These microscopic hooks cling to small surface irregularities, enabling geckos to climb absolutely smooth and vertical surfaces and even to run across smooth ceilings. Some geckos also have retractable claws. Like snakes, most geckos have a clear protective covering over the eyes. The pupils of common nocturnal species are vertical and are often lobed in such a manner that they close to form four pinpoints. The tails of geckos may be long and tapering, short and blunt, or even globular. The tail probably serves in some species as a storehouse of reserve nutrient on which the animal can draw during unfavourable conditions. The tail may also be extremely fragile and if detached is quickly regenerated in its original shape. Geckos' colours are usually drab, with grays, browns, and dirty whites predominating, though one genus, *Phelsuma*, of Madagascar, comprises bright green types active in the daytime. Unlike other reptiles, most geckos have a voice, the call differing with the species and ranging from a feeble click or chirp to a shrill cackle or bark. Most species are oviparous, the eggs being white and hard-shelled and usually laid beneath the bark of trees or attached to the underside of leaves. A few species in New Zealand have live births.

Geckos are abundant throughout the warm areas of the world, at least a few species occurring on each continent. The banded gecko (*Coleonyx variegatus*), the most widespread North American species, grows to 15 cm and is pinkish to yellowish tan with darker bands and splotches. The tokay gecko (*Gekko gecko*),

the largest species, attains a length of 25 to 35 cm (10 to 14 inches). It is gray with red and whitish spots and bands. The tokay gecko, native to Southeast Asia, is frequently sold in pet shops.

**Ged, William** (b. 1690, Edinburgh, Scot.—d. Oct. 19, 1749, Leith, Midlothian), Scottish goldsmith who invented (1725) stereotyping, a process in which a whole page of type is cast in a single mold so that a printing plate can be made from it. His work was opposed by typefounders and composers, and the process was abandoned until the early 1800s.

Although Ged's system made fair copy, the opposition to his work resulted in its complete rejection by printers. He experimented in secret and won a contract to supply Bibles and prayer books to the University of Cambridge, but he was ruined by the dishonesty of his London collaborator. He then became a goldsmith and jeweler.

**Gedaliah, fast of**, a minor Jewish observance (on Tishri 3) that mournfully recalls the assassination of Gedaliah, Jewish governor of Judah and appointee of Nebuchadrezzar, the Babylonian king. Gedaliah, a supporter of Jeremiah, was slain by Ishmael, a member of the former royal family of Judah. When the remaining Jews fled to Egypt, Jewish self-rule was thus effectively ended. Liturgically, the fast of Gedaliah follows the ritual of other fast days but adds certain penitential prayers. The festival is postponed one day if Tishri 3 falls on the Sabbath.

**Geddes, James** (b. July 22, 1763, near Carlisle, Pa. [U.S.]—d. Aug. 19, 1838, Geddes, N.Y., U.S.), American civil engineer, lawyer, and politician who played a leading role in the construction of the Erie Canal, one of the first great engineering works in North America.

Around 1794 Geddes moved from his birthplace to Syracuse, N.Y., where he worked in the salt industry. He later studied law, was admitted to the bar, and in 1804 won a seat in the New York State Assembly. While serving in the Assembly, he met the New York surveyor general, Simeon DeWitt, who persuaded him that a canal connecting the Hudson River and the Great Lakes was feasible. Geddes then traveled around the state to gather information and to arouse enthusiasm; despite his lack of technical training, he surveyed a possible route in 1808 and reported his findings to the Assembly on Jan. 20, 1809. The route he proposed at that time was close to the one eventually followed. Between 1816 and 1822 Geddes was one of the four principal engineers involved in the construction of this, the Erie Canal, which helped to establish New York City as one of the most important ports in the United States.

In 1822 Geddes directed the construction of a canal in Ohio and six years later planned a canal in Pennsylvania. He also served one term in the U.S. Congress (1813–15).

**Geddes, Norman Bel**, original name NORMAN MELANCTON GEDDES (b. April 27, 1893, Adrian, Mich., U.S.—d. May 8, 1958, New York, N.Y.), American theatrical designer whose clean, functional decors contributed substantially to the trend away from naturalism in 20th-century stage design. As an important industrial designer he helped popularize "streamlining" as a distinct modern style.

Following brief study at the Cleveland Institute of Art and the Art Institute of Chicago, Geddes became interested in the theatre and staged his first play, *Nju*, and five others for the Los Angeles Little Theatre in 1916. In New York City in 1918 he did scenic designs for the Metropolitan Opera. He designed, produced, or directed some 200 operas, films, plays, and musical comedies.

Toward the end of the 1920s, Geddes adapted his ideas to industrial design, gradually building an organization that employed 2,000

people. His designs ranged from skyscrapers, inkwells, yachts, radios, and interiors to refrigerators. One of his best-remembered designs was the General Motors Futurama building and exhibit at the New York World's Fair (1939–40). Geddes also designed theatres worldwide. He staged circuses, developed equipment and techniques for the armed services, and wrote books on many subjects.

An autobiography, *Miracle in the Evening* (1960), edited by William Kelley, depicts the designer through his theatrical work.

**Geddes, Sir Patrick** (b. Oct. 2, 1854, Ballater, Aberdeen, Scot.—d. April 17, 1932, Montpellier, Fr.), Scottish biologist and sociologist who was one of the modern pioneers of the concept of town and regional planning.

Greatly influenced by Charles Darwin's evolutionary arguments and their application to society, Geddes chose to study biology in London under Darwin's champion, Thomas Henry Huxley. While professor of botany at University College in Dundee, Angus (1889–1919), he emphasized the development of sexual reproduction as a major step in organic evolution and, with the naturalist John Arthur Thomson, published *The Evolution of Sex* (1889).

Geddes turned his attention to sociology after an attack of blindness in Mexico hampered his biological experimentation. His researches in India, where he served as professor of sociology and civics at Bombay University (1920–23), and in Palestine, Mexico, and Scotland formed the basis of his conviction that the development of human communities was primarily biological in nature, consisting of interactions among people, their environment, and their activities. He developed an innovative philosophy of urban planning, summarized in *City Development* (1904) and *Cities in Evolution* (1915). After his return from India, Geddes directed Scots College in Montpellier. He was knighted in 1932.

**BIBLIOGRAPHY.** Studies of his life and ideas include Paddy Kitchen, *A Most Unsettling Person* (1975); Philip Boardman, *The Worlds of Patrick Geddes: Biologist, Town Planner, Re-educator, Peace-warrior* (1978); and Helen Meller, *Patrick Geddes: Social Evolutionist and City Planner* (1990).

**Gedeon** (Old Testament hero): see Gideon.

**Gediminas** (Lithuanian), Polish GEDYMIN (b. c. 1275—d. 1341), grand duke of Lithuania, the strongest contemporary ruler of eastern Europe.

Gediminas succeeded his brother Vytenis (Witen) in 1316 and started the Gedimian dynasty, which included his grandson Jagiello, later Wladyslaw II of Poland. Gediminas' domain was composed not only of Lithuania proper and Samogitia but also of Volhynia, the northwestern Ukraine, and Belorussia to the Dnieper River. It was his difficult task to neutralize the threat of the Teutonic and Livonian Knights while still maintaining the delicate balance between his pagan Lithuanian and Samogitian subjects, his Orthodox subjects in Russia, and his occasional Roman Catholic allies in Poland and Riga. Gediminas' policy, therefore, was necessarily tentative and ambiguous.

In 1322 and 1323 he wrote to Saxon Dominicans and Franciscans and to several cities of the Hanseatic League, offering protection and privileges to monks, merchants, and artisans who would accept his invitation to settle in Lithuania. He also opened direct negotiations with the Holy See, soliciting Pope John XXII's protection against the Knights and claiming that the necessity of national defense against them, rather than any hostility to the church, had kept Lithuania pagan. In October 1323 various ecclesiastical representatives and the grand master of the Teutonic Order assembled at Vilnius, which Gediminas had

recently made his capital, and a compact was signed confirming peaceful relations.

The Teutonic Knights, however, strove to nullify Gediminas' gains and refused to abide by the treaty. In response, Gediminas made an alliance with the archbishop and citizens of Riga, attained peaceful promises from his other neighbours, and further strengthened his position by entering an alliance with Roman Catholic Poland and marrying his daughter Aldona to Casimir, son of King Wladyslaw I the Short, in 1325. The Teutonic Knights thereupon resumed the war against Gediminas, and for the remainder of his reign he was primarily concerned with defending his realm against the Knights, whose strength was reinforced by Western crusaders when it became evident that Gediminas would not honour his promise of conversion.

**Gedling**, district (borough), county of Nottinghamshire, east-central England. With an area of 46 square miles (120 square km), the district takes its name from the former village of Gedling, which was engulfed in the expansion of the eastern suburbs of the city of Nottingham. The district extends from the River Trent in the south to the outskirts of Hucknall and Kirkby-in-Ashfield in the northwest and includes much of Sherwood Forest. Pop. (2001) 111,776.

**Gedrosia**, historic region west of the Indus River, in what is now the Baluchistan region of Pakistan. In 325 bc Alexander the Great's forces suffered disastrous losses there from the effects of the desert, supply shortages, and monsoons. They captured the area, but after Alexander's death his general Seleucus Nicator was forced to make peace with Chandragupta Maurya by trading Gedrosia and all his territories east of the Hindu Kush for 500 elephants. His departure ended Greek intervention on the subcontinent of India.

**Gedymin** (Lithuanian ruler): see Gediminas.

**Gee, Kenneth** (b. 1916, Wigan, Lancashire, Eng.), English rugby player, a member of the powerful Wigan club that won the Rugby League (RL) Challenge Cup in 1948. He was also vital as forward in Wigan's RL championship wins of 1945–46, 1946–47, and 1949–50 and the Challenge Cup victory of 1951.

During his career, Gee kicked 528 goals and scored 58 tries (touchdowns). His domineering plays between 1935 and 1955 earned him 17 British caps. He toured Australia in 1946 and 1950.

**Geel**, also spelled GHEEL, *commune*, Antwerp province, northern Belgium, in the Kempenland (Campine) Plateau, east of Antwerp. Renowned for its unique system of family care for the mentally ill, it is linked by tradition with the Irish martyr St. Dymphna, who was beheaded there by her pagan father in the 7th century and at whose tomb persons suffering from mental illness are said to have been cured. A cathedral was built in her honour, and the afflicted pilgrims were accommodated in a sickroom built next to the church. When the room became too crowded (c. 14th century), the patients were lodged in the homes of the inhabitants. In 1850 this religious-municipal system became a medically supervised government institution.

Served by railroads, canals, and highways, and having some small industries, Geel is now part of the Zuiderkempen, an area zoned for industrial development. The city contains a 16th-century church and a 17th-century town hall. Pop. (1991) mun., 32,487.

**Geelong**, second largest city of Victoria, Australia, and a major port on Corio Bay (an extension of Port Phillip Bay). Founded in 1837, its name is a derivation of the Aboriginal word *jillong*, which means "the place of the native companion," referring to a long-legged water bird. Formally declared a town

in 1838, it was proclaimed a municipality in 1849. Depopulated by news of gold strikes (1851), Geelong began to recover when its rail link to Melbourne was completed (1857). It became a city in 1910 and grew rapidly after World War II.

The city is a transportation hub. Besides its port, which ranks high nationally in total trade, there are rail lines to Melbourne, Ballarat, and the Western District (an area of sheep farms, intensive agriculture, and pine plantations), the Prince's Highway to South Australia, and the Great Ocean Road along the southwest coast.

Geelong markets a significant portion of Australia's total wool clip. It ships crude and refined petroleum, grains (including a large portion of the Australian wheat export), meat, steel, and motor vehicles and parts. Other industries include the manufacture of woollens, automobiles, rope and cordage, superphosphate fertilizers, agricultural machinery, glass, and petrochemicals. Aluminum is refined at nearby Point Henry.

Geelong is an educational centre with a large library, the Gordon Institute of Technology (textiles), and several private schools, notably the Anglican Geelong Grammar School (1854). Deakin University was founded in 1977. Laboratories of the Commonwealth Scientific and Industrial Research Organization have done much to improve the area's sheep industry. The city, 40 percent of whose area is parkland, is the centre of a resort district that includes several neighbouring coastal towns. Pop. (2001 prelim.) 194,902.

**Geer, Dirk Jan de** (b. Dec. 14, 1870, Groningen, Neth.—d. Nov. 28, 1960, Soest), conservative statesman and prime minister of The Netherlands (1926–29, 1939–40) who was disgraced for attempting to negotiate a peace settlement between Great Britain and Nazi Germany in 1940.

After receiving his doctorate in law in 1895, de Geer worked as a journalist and acted as town councillor of Rotterdam (1901–07). He served as a Christian Historical member of Parliament (1907–21), minister of finance (1921–23, 1926–33, 1939–40), and minister of the interior (1925–26). He continued his second term as prime minister in London after the German invasion of The Netherlands in May 1940.

De Geer's abortive attempt to mediate between Great Britain and Germany following the collapse of France in June 1940 was disavowed by Queen Wilhelmina of The Netherlands and her Cabinet (in exile in England), and he resigned on Sept. 3, 1940. He was then entrusted with a mission to the Dutch East Indies but instead returned to The Netherlands and was denounced on a Netherlands government-in-exile broadcast (Radio Orange) from London on Feb. 6, 1941. For his mediation efforts of 1940 he was, on May 23, 1947, fined 20,000 guilders and sentenced to one year's imprisonment. The prison sentence was suspended because of his poor health and advanced age.

**Geer, Gerhard (Jakob), Friherre De:** see De Geer, Gerhard (Jakob), Friherre.

**Ge'ermu** (China): see Golmud.

**Geert Groote** (Dutch religious leader): see Groote, Geert.

**Geertgen TOT SINT JANS** (b. c. 1465—d. c. 1495), Dutch painter of religious subjects, notable for his harmonious fusion of the elements of the landscape.

Little is known of Geertgen's life: his surname derived from his living with the religious order of the Knights of St. John at Haarlem, Neth., where he was a pupil of the painter

Ouwater at Haarlem. Many of his works have been destroyed, but portions of his masterpiece, a large triptych for the high altar of the Knights of St. John, survive. One wing, preserved in the Vienna gallery of painting and fine arts, presages the great portrait groups of 17th-century Dutch painting.

"St. John the Baptist in the Wilderness," panel by Geertgen tot Sint Jans; in the State Museum of Berlin—Prussian Cultural Heritage

By courtesy of the Staatliche Museen Preussischer Kulturbesitz Gemäldegalerie, Berlin

Several other paintings are ascribed to Geertgen on stylistic grounds, such as "St. John the Baptist in the Wilderness" and "Virgin and Child" in Berlin, "The Resurrection of Lazarus" in the Louvre (Paris), "The Virgin's Kindred" and "Adoration of the Magi" in Amsterdam, "The Man of Sorrows" at Utrecht, and a triptych in Prague. His "Nativity" in the National Gallery, London, is a night scene remarkable for its rendering of chiaroscuro.

**Geertz, Clifford**, in full CLIFFORD JAMES GEERTZ (b. Aug. 23, 1926, San Francisco, Calif., U.S.), American cultural anthropologist, a leading rhetorician and proponent of symbolic anthropology and interpretive anthropology.

After service in the U.S. Navy in World War II (1943–45), Geertz studied at Antioch College, Ohio (B.A., 1950), and Harvard University (Ph.D., 1956). He taught or held fellowships at a number of schools before joining the anthropology staff of the University of Chicago (1960–70); he then became professor of social science at the Institute for Advanced Study at Princeton University (from 1970).

At Chicago, Geertz became a champion of symbolic anthropology, which gives prime attention to the role of thought—of "symbols"—in society. Symbols guide action. Culture, according to Geertz, is "a system of inherited conceptions expressed in symbolic forms by means of which men communicate, perpetuate, and develop their knowledge about and attitudes toward life." The function of culture is to impose meaning on the world and make it understandable. The role of anthropologists is to try—though complete success is not possible—to interpret the guiding symbols of each culture.

Geertz's writings tend to be rhetorical and idiosyncratic, more given to metaphors and

examples than bald exposition. Among his major works are *The Religion of Java* (1960), *Person, Time, and Conduct in Bali* (1966), *The Interpretation of Cultures* (1973), *Local Knowledge: Further Essays in Interpretive Anthropology* (1983), and *Works and Lives: The Anthropologist as Author* (1988).

**Ge'ez language**, also spelled GEEZ, also called ETHIOPIC, liturgical language of the Ethiopian church. Ge'ez is a Semitic language of the Southern Peripheral group, to which also belong the South Arabic dialects and Amharic, the official language of Ethiopia. Both Ge'ez and the related languages of Ethiopia are written and read from left to right, in contrast to the other Semitic languages.

Extinct as a vernacular language, Ge'ez is the ancestor of the modern Tigrinya and Tigré languages of Eritrea and Ethiopia. The oldest known inscription in the language dates from the 3rd or 4th century and is written in a script that does not indicate vowels. Subsequent inscriptions found in the ancient Ethiopian capital of Aksum were written from the 4th through the 9th century in a script that does indicate vowels. The Bible was translated into Ge'ez between the 5th and 7th centuries. Although the language ceased to be spoken popularly sometime between 900 and 1200, it continues as a liturgical language; the period of classical Ge'ez literature was between the 13th and 17th centuries.

**Gefara** (Africa): see Jifārah, Al-

**Gegenbaur, Karl** (b. Aug. 21, 1826, Würzburg, Bavaria [Germany]—d. June 14, 1903, Heidelberg, Ger.), German anatomist who demonstrated that the field of comparative anatomy offers important evidence in support of evolutionary theory.

A professor of anatomy at the universities of Jena (1855–73) and Heidelberg (1873–1903), Gegenbaur was a strong supporter of Charles Darwin's theory of organic evolution. His *Grundzüge der vergleichenden Anatomie* (1859; *Elements of Comparative Anatomy*) became the standard textbook of evolutionary morphology, emphasizing that structural similarities in different animals constitute clues to their evolutionary history. In this work Gegenbaur stated that "the most important part of the business of comparative anatomy is to find indications of genetic connections in the organization of the animal body." He pointed out that the most reliable clue to these connections is homology, the comparison of those parts that have a common evolutionary origin, such as a man's arm, a horse's foreleg, and a bird's wing.

Gegenbaur confirmed German zoologist Theodor Schwann's hypothesis that all eggs and sperm are single cells (1861), and he supported the British biologist Thomas Huxley in disproving the concept that the vertebrate skull arose from expanded vertebrae.

**gegenschein**, also called COUNTERGLOW, oval patch of faint luminosity exactly opposite to the Sun in the night sky. The patch of light is so faint it can be seen only in the absence of moonlight, away from city lights, and with the eyes adapted to darkness. The gegenschein is lost in the light of the Milky Way in the summer and winter. The best observing periods are February, March, April, August, September, and October. The gegenschein and the zodiacal light, a similar phenomenon not restricted to a position opposite the Sun, form the most notable parts of a band of very faint light along the ecliptic. The spectrum of the gegenschein is similar to that of the Sun, and it is generally believed that it is the result of the reflection of sunlight from meteoric material or other dust in the Earth's orbital plane.

**Gehenna**, also called GEHINNOM, abode of the damned in the afterlife in Jewish and Christian eschatology (the doctrine of last things).

Named in the New Testament in Greek form (from the Hebrew Ge Hinnom, meaning "valley of Hinnom"), Gehenna originally was a valley west and south of Jerusalem where children were burned as sacrifices to the Ammonite god Moloch. This practice was carried out by the Israelites during the reigns of King Solomon in the 10th century BC and King Manasseh in the 7th century BC and continued until the Babylonian Exile in the 6th century BC. Gehenna later was made a garbage centre to discourage a reintroduction of such sacrifices.

The imagery of the burning of humans supplied the concept of "hellfire" to Jewish and Christian eschatology. Mentioned several times in the New Testament (e.g., Matthew, Mark, Luke, and James) as a place in which fire will destroy the wicked, it also is noted in the Talmud, a compendium of Jewish law, lore, and commentary, as a place of purification, after which one is released from further torture.

**gehlenite**, mineral composed of calcium aluminum silicate, Ca<sub>2</sub>Al<sub>2</sub>SiO<sub>7</sub>, one end-member of the melilite mineral series (see melilite).

**Gehrig, Lou**, byname of HENRY LOUIS GEHRIG (b. June 19, 1903, New York, N.Y., U.S.—d. June 2, 1941, New York City), one of the most durable players in American professional baseball and one of its great hitters. From June 1, 1925, to May 2, 1939, the "Iron Horse," playing first base for the New York Yankees, appeared in 2,130 consecutive games, a record that stood until it was broken on Sept. 6, 1995, by Cal Ripken, Jr., of the Baltimore Orioles.

Gehrig attended Columbia University before joining the Yankees' organization. In each of seven major league seasons, he batted in 150 or more runs, and in 1931 he established the American League record of 184, which persisted into the 1980s. On June 3, 1932, he hit four consecutive home runs in one game. In 1934 he led the American League in batting average, home runs, and runs batted in. In that season, and again in 1936, he hit 49 home runs. He left baseball with a career batting average of .340, 493 home runs, and 1,990 runs batted in, all during regular season play. In seven World Series (34 games), he batted .361, hit 10 home runs, and drove in 35 runs.

A quiet, gentle man, Gehrig was somewhat

Gehrig, 1939  
AP/Wide World Photos

overshadowed by his colourful teammate Babe Ruth, whom he followed in the Yankees' batting order. In 1939, when it was known that Gehrig was dying of amyotrophic lateral sclerosis, he was elected to the Baseball Hall of Fame.

**Gehry, Frank O.**, in full FRANK OWEN GEHRY, original name FRANK OWEN GOLDBERG (b. Feb. 28, 1929, Toronto, Ont., Can.), American architect and designer whose original, sculptural, often audacious work won him worldwide renown.

Gehry's family immigrated to Los Angeles in 1947. He studied architecture at the University of Southern California (1949–51; 1954) and city planning at Harvard University (1956–57). After working for several architectural firms, he established his own company, Frank O. Gehry & Associates, in 1962.

Reacting, like many of his contemporaries, against the cold and often formulaic Modernist buildings that had begun to dot many cityscapes, Gehry began to experiment with unusual expressive devices and search for a personal vocabulary. In his early work, he built unique, quirky structures that emphasized human scale and contextual integrity. His early experiments are perhaps best embodied by the "renovations" he made to his own home (1978, 1991–94) in Santa Monica, Calif. Gehry essentially stripped down the two-story home to its frame and then built a chain-link and corrugated-steel frame around it, complete with asymmetrical protrusions of steel rod and glass. Gehry made the traditional bungalow—and the architectural norms it embodied—appear to have exploded wide open. He continued these design experiments in two popular lines of corrugated cardboard furniture, *Easy Edges* (1969–73) and *Experimental Edges* (1979–82). Gehry's ability to undermine the viewer's expectations of traditional materials and forms has led him to be grouped with the deconstructivist movement in architecture, although his play upon architectural tradition has also caused him to be linked to Postmodernism.

Treating each new commission as "a sculptural object, a spatial container, a space with light and air," Gehry was rewarded with commissions the world over throughout the 1980s and '90s. These works possessed the deconstructed quality of his Santa Monica home but began to display a pristine grandeur that suited his increasingly public projects. Notable structures from the period include the Vitra Furniture Museum and Factory (1987) in Weil am Rhein, Ger.; the American Center (1988–94) in Paris; and the Frederick R. Weisman Art Museum (1990–93) at the University of Minnesota in Minneapolis.

The Guggenheim Museum, Bilbao, Spain, designed by Frank Gehry, 1991–97

Richard Bryant—Arcad

Gehry's reputation soared in the late 1990s. By this time, Gehry's trademark style had become buildings that resemble undulating, free-form sculpture. This form arguably reached its zenith in his Guggenheim Museum (1991–97)

in Bilbao, Spain. In this structure, Gehry combined curvaceous, titanium forms with interconnecting limestone masses to create a sculptural feat of engineering. He further explored these concerns in the Experience Music Project (1995–99) in Seattle, Wash. Constructed of a fabricated steel frame wrapped in colourful sheet metal, the structure was, according to Gehry, modeled on the shape of a guitar—particularly, a smashed electric guitar. As with the Guggenheim structure, he employed cutting-edge computer technology to uncover the engineering solutions that could bring his sculptural sketches to life. In his seventies at the turn of the 21st century, Gehry continued to be offered numerous large-scale commissions.

**Geiami** (Japanese artist): see Shingei.

**Geibel, Emanuel von**, in full FRANZ EMANUEL AUGUST VON GEIBEL (b. Oct. 17, 1815, Lübeck [Germany]—d. April 6, 1884, Lübeck, Ger.), German poet and dramatist who was the centre of a circle of literary figures drawn together in Munich by Maximilian II of Bavaria. This group belonged to the *Gesellschaft der Krokodile* ("Society of the Crocodiles"), a literary society that cultivated traditional poetic themes and forms.

After completing his university studies, Geibel devoted himself to travel and became, in 1838, tutor to the Russian ambassador in Athens. In 1840 his extremely successful *Gedichte* ("Poems") appeared. It ran to 100 editions in his lifetime. Returning to Lübeck, he taught at the *Gymnasium* until 1852, when Maximilian called him to Munich as an honorary professor of German literature and aesthetics.

Geibel's lyrics—*Zeitstimmen* (1841; "Voices of the Times"), *Junius-Lieder* (1848; "June Songs"), and *Spätherbstblätter* (1877; "Leaves of Late Autumn")—reflect the taste of the time: classical, idealistic, and nontopical. He also made excellent translations of Romantic and ancient poets, *Spanisches Liederbuch* (1852; "Spanish Songbook"), and, with Paul von Heyse, *Klassisches Liederbuch* (1875; "Classical Songbook").

**Geiger, Abraham** (b. May 24, 1810, Frankfurt am Main—d. Oct. 23, 1874, Berlin, Ger.), German-Jewish theologian, author, and the outstanding leader in the early development of Reform Judaism.

In 1832 Geiger went to Wiesbaden as a rabbi and in 1835 helped to found the *Wissenschaftliche Zeitschrift für jüdische Theologie* ("Scientific Journal of Jewish Theology"), which he then edited. In 1838 he became junior rabbi in Breslau (now Wrocław, Pol.), where his known Reform leanings aroused Orthodox opposition. Remaining in Breslau until 1863

(he became senior rabbi in 1843), Geiger organized the Reform movement there and wrote some of his most important works, including a translation into German of the works of Judah ben Samuel ha-Levi (1851), consid-

ered the greatest Hebrew poet of 12th-century Spain, and Geiger's own magnum opus, *Urschrift und Übersetzungen der Bibel in ihrer Abhängigkeit von der innern Entwicklung des Judentums* (1857; "The Original Text and the Translations of the Bible: Their Dependence on the Inner Development of Judaism"). In the latter work, Geiger analyzes the Sadducees and the Pharisees, Jewish sects in whose history he sees a paradigm of a basic idea of Reform Judaism: in some respects, the Jewish religious consciousness grows and changes, and this development is reflected in the succeeding editions and translations of the Bible.

In a series of rabbinical conferences at Brunswick (1844), Frankfurt (1845), and Breslau (1846), Geiger incisively presented other main tenets of Reform Judaism: the necessity of simplifying ritual and of using a liturgy spoken in one's native tongue; an emphasis on the prophetic teachings as presenting the core of Judaism; and a deemphasis on a return to the land of Israel. Geiger's last years were spent as a rabbi at Frankfurt and at Berlin.

**Geiger, Hans**, byname of JOHANNES WILHELM GEIGER (b. Sept. 30, 1882, Neustadt an der Haardt, Ger.—d. Sept. 24, 1945, Potsdam), German physicist who introduced the first successful detector (the Geiger counter) of individual alpha particles and other ionizing radiations.

Geiger was awarded the Ph.D. by the University of Erlangen in 1906 and shortly thereafter joined the staff of the University of Manchester, where he became one of the most valuable collaborators of Ernest Rutherford. At Manchester, Geiger built the first version of his particle counter and used it and other radiation detectors in experiments that led to the identification of the alpha particle as the nucleus of the helium atom and to Rutherford's correct proposal (1912) that, in any atom, the nucleus occupies a very small volume at the centre.

Moving in 1912 to the *Physikalisch-Technische Reichsanstalt* ("German National Institute for Science and Technology") in Berlin, Geiger continued his studies of atomic structure. With Walther Bothe, Geiger devised the technique of coincidence counting and used it in 1924 to clarify the details of the Compton effect. In 1925 Geiger accepted his first teaching position, at the University of Kiel. There, he and Walther Müller improved the sensitivity, performance, and durability of the particle counter; the Geiger-Müller counter detects not only alpha particles but beta particles (electrons) and ionizing electromagnetic photons. In 1929 Geiger took up a post at the University of Tübingen, where he made his first observation of a cosmic-ray shower. He continued to investigate cosmic rays, artificial radioactivity, and nuclear fission after accepting a position in 1936 at the Technische Hochschule in Berlin, which he held until he died.

**Geiger, Rudolf Oskar Robert Williams** (b. Aug. 24, 1894, Erlangen, Ger.—d. 1981), German meteorologist, one of the founders of microclimatology, the study of the climatic conditions within a few metres of the ground surface. His observations, made above grassy fields or areas of crops and below forest canopies, elucidated the complex and subtle interactions between vegetation and the heat, radiation, and water balances of the air and soil.

Geiger taught and conducted his research at several institutions in Germany. He was the author of the classic treatise *Das Klima der bodennahen Luftschicht* (1927; *The Climate near the Ground*), a comprehensive survey of microclimatology observations and of the effects of microclimate on plants, animals, and humans.

**Geiger, Theodor Julius** (b. Nov. 9, 1891, Munich, Ger.—d. June 16, 1952, at sea), Ger-

man sociologist and first professor of sociology in Denmark, whose most important studies concerned social stratification and social mobility.

Geiger served in World War I, after which he returned to Munich to take his doctorate in law. He was a teacher, journalist, and government statistician in Berlin and then was a professor of sociology (1928–33) at the Brunswick Institute of Technology. After the rise to power of the Nazis, of whom he was an early critic, he fled to Copenhagen. There a Rockefeller Foundation fellowship and an appointment to the Institute of History and Economics sustained him until 1938, when he was given a full professorship at the University of Århus, in Denmark. During the German occupation of Denmark in World War II, Geiger was exiled again and went to Sweden, teaching at the universities of Stockholm and Uppsala. After the war Geiger returned to Århus (1945), where he founded and directed the first Scandinavian institute of sociological research and developed the academic journal *Acta Sociologica*.

Influenced by Marxism, he believed for a time in the existence (specifically in Germany) of a well-defined class structure; but by 1948, when his *Klassensamfundet i Støbergryden* ("Class Society in the Melting Pot") was published, he had abandoned that idea. His basic textbook was *Sociologi* (1939).

His work on social stratification and mobility included studies of Danish intellectuals and a detailed examination of the people of Århus, *Soziale Umschichtungen in einer dänischen Mittelstadt* (1951; "Social Changes in a Medium-Sized Danish City"). Several of his works were published posthumously: *Ideologie und Wahrheit* (1953; "Ideology and Truth") discusses ideology and its role in the creation of mass society; and *Demokratic ohne Dogma* (1964; "Democracy Without Dogma") is notable for Geiger's vision of a society depersonalized by ideology but redeemed by human relationships. Geiger died at sea when he was returning from a year as visiting professor in Toronto.

**Geiger counter**, also called GEIGER-MÜLLER COUNTER, type of ionization chamber (*q.v.*) especially effective for counting individual particles of radiation.

**Geijer, Erik Gustaf** (b. Jan. 12, 1783, Ransäter, Värmland, Sweden—d. April 23, 1847, Stockholm), Swedish poet, historian, philosopher, and social and political theorist who was a leading advocate, successively, of the conservative and liberal points of view.

A trip to England directly after his university days made a great impression on Geijer and gave him political insight into the life of a major European power. A collection of his

diaries and letters was published as *Geijer i England* (1814; *Impressions of England*). The defeat that Sweden suffered in 1809 through the loss of Finland to Russia led him to a rather extreme nationalism. He was one of the founders, in 1811, of the Götska Förbundet ("Gothic Society"), which aimed at furthering national feeling through historical study. In 1817 Geijer became professor of history at Uppsala University. His main historical works are *Svea rikets räfder* (1825; "The Annals of the Kingdom of Sweden") and *Svenska folkets historia*, 3 vol. (1832–36; *The History of the Swedes*). Geijer's historical investigations, however, rather than furthering his conservatism, brought him to radically new political ideas: universal suffrage, equal educational opportunities for all, and elimination of poverty.

In the posthumously published philosophical *Människans historia* (1856; "Man's History"), Geijer interpreted historical events as a combination of tradition and creation. Some of his best poems are those set to his own music and written between 1838 and 1841. They were published in his collected works (1849–55).

**Geisel, Ernesto** (b. Aug. 3, 1908, Bento Gonçalves, Brazil—d. Sept. 12, 1996, Rio de Janeiro), army general who was president of Brazil from 1974 to 1979.

A career army officer, Geisel joined the military coup led by Getúlio Vargas that overthrew the elected government and installed a dictatorship in 1930. Geisel supported Vargas for 15 years, serving in a variety of military and civil administrative posts, but in 1945 he played an important part in overthrowing Vargas' government. Over the course of the next 15 years he held several important offices, including deputy chief of the military staff of the presidency and military representative to the National Petroleum Council, gaining a reputation for incisive leadership. He participated in the military coup of 1964 and became chief of President Humberto Castelo Branco's military staff. In 1969 Geisel took charge of Petrobrás, the national oil corporation, expanding its scope and increasing production dramatically.

Placed in the presidency by the military oligarchy (March 15, 1974), Geisel risked their opposition by beginning a gradual liberalization and demilitarization of the government, permitting open legislative elections in 1974, meeting with opposition leaders, and relaxing censorship. He outlined a new economic policy, "pragmatic nationalism," which called for shifting emphasis from exports to the development of domestic industry, such as mining, agriculture, and transportation networks. Although there had been some indication that he might be succeeded by an elected civilian president, Geisel and his conservative supporters saw that they would be defeated in open elections. Accordingly, Geisel took no further steps toward democratization, and official repression of the political opposition increased in 1977. Geisel did not run for reelection in 1979 but instead supported General João Baptista de Oliveira Figueiredo, his successor.

**Geisel, Theodor Seuss**, pseudonym DOCTOR SEUSS (b. March 2, 1904, Springfield, Mass., U.S.—d. Sept. 24, 1991, La Jolla, Calif.), American writer and illustrator of immensely popular children's books.

After undergraduate work at Dartmouth College, Hanover, N.H., and postgraduate work at Lincoln College, Oxford, and at the Sorbonne, Geisel began working for *Life*, *Vanity Fair*, and other publications as an illustrator and humorist. After service in the army during World War II, Geisel went into advertising for a time, was made an editorial cartoonist for *PM* newspaper in New York City, and eventually in 1958 founded Beginner Books, Inc., which in 1960 became a division of Random House.

Geisel's books were valued not only for their unique brand of humour but also for their contribution to the education of children. The books coined new nonsense words and animal characters that went far beyond the traditional primers. They include *And To Think That I Saw It on Mulberry Street* (1937), *Horton Hatches the Egg* (1940), *How the Grinch Stole Christmas* (1957), *The Cat in the Hat* (1957), *Green Eggs and Ham* (1960), and *The Lorax* (1971).

Geisel also made documentary films; *Hitler Lives* (1946) and *Design for Death* (1947, with his wife Helen Palmer Geisel [d. 1967]), both won Academy Awards. His animated cartoon *Gerald McBoing Boing* (1951) also won an Academy Award. He designed and produced animated cartoons for television, many of them based on his books.

**geisha**, a member of a professional class of women in Japan whose traditional occupation is to entertain men, in modern times, particularly at businessmen's parties in restaurants or teahouses. The Japanese word *geisha* literally means "art person," and singing, dancing, and playing the *samisen* (a lutelike instrument) are indispensable talents for a geisha, along with the ability to make conversation. Many geisha are also adept at flower arranging, performing the tea ceremony, or calligraphy. The main function of the geisha is to provide an atmosphere of chic and gaiety for her wealthy clientele. Geisha are usually exquisitely dressed in traditional kimonos and delicately mannered and have a knowledge not only of the past but also of contemporary gossip.

The geisha system is thought to have emerged in the 17th century to provide a class of entertainers set apart from courtesans and prostitutes, who plied their trades respectively among the nobility and samurai. The geisha system was traditionally a form of indentured labour, although some girls, attracted by the glamour of the life, volunteered. Usually, a girl at an early age was given by her parents for a sum of money to a geisha house, which taught, trained, fed, and clothed her for a period of years. Then she emerged into the society known as *karyūkai* (the "flower and willow world") and began earning money to repay her parents' debt and her past keep. The most sought-after geisha could command large sums from their customers. Besides providing entertainment and social companionship, geisha sometimes maintained sexual relationships with their clients.

In the 1920s there were as many as 80,000 geisha in Japan, but by the late 20th century their number had dwindled to only a few thousand, almost all confined to Tokyo and Kyōto, where they were patronized by only the wealthiest businessmen and most influential politicians. This decline in numbers was chiefly due to the easier availability of more casual forms of sex in postwar Japan; bar hostesses have taken over the geisha's role with the ordinary Japanese businessman.

When a geisha marries, she retires from the profession. If she does not marry, she usually retires as a restaurant owner, teacher of music or dance, or trainer of young geisha.

**Geissler, Heinrich**, in full JOHANN HEINRICH WILHELM GEISSLER (b. May 26, 1815, Igelshieb, Thuringia, Saxe-Meiningen [Germany]—d. Jan. 24, 1879, Bonn, Prussia [Germany]), German glassblower for whom the Geissler (mercury) pump and the Geissler tube are named.

Geissler opened a shop in Bonn in 1854 to make scientific apparatus and devised his mercury air pump in 1855. Later, using an apparatus of his own invention, he was able to demonstrate, in collaboration with Julius Plücker, that water reaches its maximum density at 3.8° C (later determined to be 3.98°). Among

Geijer, detail of an oil painting by J.G. Sandberg, 1828; in the Nationalmuseum, Stockholm

By courtesy of the Nationalmuseum, Stockholm

his other inventions were the vaporimeter and the Geissler tube, in which an electric current produces light when passed through a rarefied gas.

**Gejiu** (China): see Ko-chiu.

**gekko** (lizard): see gecko.

**Gekoyo** (people): see Kikuyu.

**gel**, coherent mass consisting of a liquid in which particles too small to be seen in an ordinary optical microscope are either dispersed or arranged in a fine network throughout the mass. A gel may be notably elastic and jellylike (as gelatin or fruit jelly), or quite solid and rigid (as silica gel, a material that looks like coarse white sand and is used as a dehumidifier). Gels are colloids (aggregates of fine particles, as described above, dispersed in a continuous medium) in which the liquid medium has become viscous enough to behave more or less as a solid. Contraction of a gel, causing separation of liquid from it, is called syneresis. *Compare* sol.

**gel chromatography**, also called **GEL FILTRATION**, in analytical chemistry, technique for separating chemical substances by exploiting the differences in the rates at which they pass through a bed of a porous, semisolid substance. The method is especially useful for separating enzymes, proteins, peptides, and amino acids from each other and from substances of low molecular weight. The separation of the components of a mixture by gel chromatography is based on the differences in the molecular sizes of the components. Small molecules tend to diffuse into the interior of the porous particles so that their flow is restricted, while large molecules are unable to enter the pores and tend to flow unhindered. Thus, the components of highest molecular weight leave the bed first, followed by successively smaller molecules. The bed materials most extensively used are polyacrylamide and a polymer prepared from dextran and epichlorohydrin. The dry polymers are usually suspended in suitable agents to form a homogeneous, semisolid mixture.

**Gela**, town, Caltanissetta province, southern Sicily, Italy, on the Gulf of Gela (of the Mediterranean Sea) with a fertile plain (ancient Campi Geloi) to the north. It was founded by Cretan and Rhodian colonists c. 688 BC and sent forth colonists to found Acragas (now Agrigento, 45 mi [72 km] northwest) in c. 581 BC. Gela enjoyed its greatest prosperity under the tyrant Hippocrates of Gela (498–491 BC), whose dominion extended over much of the island, but his even more powerful successor, Gelon, took possession of Syracuse unopposed and transferred his capital and half of the pop-

ulation there in 482. Gela later revived, but it was destroyed by the Carthaginians in 405 BC and abandoned by order of Dionysius I the Elder of Syracuse. The inhabitants returned and rebuilt the town but it was only refortified c. 337 in the time of the Greek statesman Timoleon. In 311 BC the Syracusan tyrant Agathocles put to death more than 4,000 of the inhabitants and, after its destruction by the Mamertini (Campanian mercenaries) in 281 BC, Phintias of Acragas transferred the remainder to the new town of Phintias (now Licata). Refounded in 1233 by Frederick II, the town was known as Terranova di Sicilia until 1928. In World War II Gela was one of the initial objectives of Allied landings in the invasion of Sicily.

An archaeological centre of great distinction, Gela's ancient remains include a temple of Athena (5th century BC), Greek fortifications that provide evidence of rebuilding under Timoleon, and the acropolis with a "Timoleontean" quarter on the site of earlier sanctuaries. Vast quantities of rich, decorative terra-cotta revetments have been recovered, and Greek vases found at Gela are famous throughout Europe.

Gela is the centre of a cotton-growing region. Fishing is important and petroleum deposits were discovered nearby in the 1950s and are today the basis of a large local petrochemical industry. Pop. (2000 est.) mun., 77,562.

**gelada** (*Theropithecus gelada*), large baboon-like monkey, family Cercopithecidae, differing

Gelada (*Theropithecus gelada*)

Tierbilder Okapia Frankfurt am Main

from true baboons (*Papio*) in having the nostrils some distance from the tip of the muzzle. The gelada, or lion baboon, is a stocky animal with white eyelids, brown fur, a tufted tail, and a naked pink chest. The male bears a long, heavy mane and may be more than 70 centimetres (28 inches) long, excluding the somewhat shorter tail, with a weight of about 20 kilograms (44 pounds). The female is markedly smaller and has a necklace-like row of bead-shaped caruncles along the edges of the bare chest patch. The gelada inhabits the mountains of southern Ethiopia and lives in groups among the steep cliffs of rocky ravines. Diurnal and terrestrial, it feeds on leaves, roots, and tubers.

**Gelasius I**, SAINT (b. probably Africa—d. Nov. 19, 496, Rome; feast day November 21), pope from 492 to 496.

Succeeding St. Felix III in March 492, Gelasius combatted the Acacian Schism that had arisen in the East under Patriarch Acacius (reigned 471–489) as a result of Rome's refusal to accept the *Henotikon*—a peace formula designed by the Eastern Roman emperor Zeno to reconcile the dissident Monophysites, advocators of the heretical doctrine that the human and divine in Christ constitute one nature. During that long, bitter struggle, Gelasius maintained papal authority, making him

one of the great architects of Roman primacy in ecclesiastical affairs.

His writings include more than 100 treatises and letters; one of the most celebrated (494) was addressed to Zeno's successor, Anastasius I, in which Gelasius states: "There are two powers by which this world is chiefly ruled: the sacred authority of the priesthood and the authority of kings." Gelasius' doctrine that both sacred and civil power are of divine origin and independent, each in its own sphere, was then the most progressive thinking on the subject; had his formula been established, the subsequent history of the papacy probably would have been different. Among his acts, in 494 he changed the Lupercalia, a Roman pagan festival, into the feast of the Purification.

*Consult the INDEX first*

**Gelasius II**, original name GIOVANNI DA GAETAN, English JOHN OF GAETA (b. Gaeta, Kingdom of Naples—d. Jan. 29, 1119, Cluny, Burgundy), pope from 1118 to 1119.

He was called to Rome from Montecassino, Italy, by Pope Urban II, who created him cardinal (1088) and papal chancellor (1089). He was elected pope on Jan. 24, 1118, as successor to Paschal II, whose pontificate had been damaged by dissension from the "investiture controversy," an administrative struggle between the popes and the Holy Roman emperors over the right to grant titles to ecclesiastics. Paschal's attempt to end the struggle with the Holy Roman emperor Henry V in 1111 had caused a revolt among the German bishops. Henry then fled Rome amidst an uprising there and took Paschal as his prisoner. Despite opposition from the Curia, Paschal—whom Gelasius fervently defended—granted Henry the right to investiture, but the controversy continued.

Gelasius' election was blackened by Henry, whose loyal supporter Cencius II Frangipani attacked and imprisoned the new pope. Driven twice from Rome by Henry, who installed Antipope Gregory VIII, Gelasius died while planning a council at Reims, leaving the close of the struggle to his successor, Calixtus II.

**gelatin**, animal protein substance having gel-forming properties, used primarily in food products and home cookery, also having various industrial uses. Derived from collagen, a protein found in animal skin and bone, it is extracted by boiling animal hides, skins, bones, and tissue after alkali or acid pretreatment. An easily digested, pure protein food, it is nutritionally an incomplete protein, deficient in certain amino acids. Unflavoured, granulated gelatin, almost tasteless and odourless, ranges from faint yellow to amber in colour. Gelatin is also available as a finely ground mix with added sugar, flavouring, acids, and colouring. When stored in dry form, at room temperature, and in an airtight container, it remains stable for long periods.

Immersed in a liquid, gelatin takes up moisture and swells. When the liquid is warmed, the swollen particles melt, forming a sol (fluid colloidal system) with the liquid that increases in viscosity and solidifies to form a gel as it cools. The gel state is reversible to a sol state at higher temperatures, and the sol can be changed back to a gel by cooling. Both setting time and sugar concentration are affected by protein and sugar concentration and by temperature. Gelatin may be whipped to form a foam and acts as an emulsifier and stabilizer. It is used to make such gel foods as jellied meats, soups, and candies, aspics, and molded desserts and to stabilize such emulsion and foam food products as ice cream, marshmal-

Doric column of the temple of Athena, 5th century BC, at Gela, Sicily

© Marani—CLICK/Chicago

lows, and mixtures of oils or fats with water. Fruit jellies resemble gelatin products but achieve solidification as a result of a natural vegetable substance called pectin.

The food industry makes use of most of the gelatin produced. Gelatin is also used by the pharmaceutical industry for the manufacture of capsules, cosmetics, ointments, lozenges, and plasma products and by other industries.

**gelatin process**, also called GELATIN DRY-PLATE PROCESS, photographic process in which gelatin is used as the dispersing vehicle for the light-sensitive silver salts. The process, introduced in about 1880, superseded the wet collodion process, in which a wet negative was produced from a nitrocellulose (collodion) solution applied to a glass plate immediately prior to exposure. This chemical treatment necessitated the presence of a darkroom wherever a photograph was to be made. The development of a process in which a sensitized gelatin emulsion could be dried on the plate and stored, protected from light, for months before use revolutionized the world of photography. Gelatin is still the standard binding medium for the silver halide crystals used in ordinary photographic film.

**Gelber, Jack** (b. April 12, 1932, Chicago, Ill., U.S.—d. May 9, 2003, New York, N.Y.), American playwright known for *The Connection* (performed 1959, published 1960) and for his association with The Living Theatre (*q.v.*), an innovative, experimental theatre group.

After graduating from the University of Illinois, Urbana, Gelber began working with the struggling Living Theatre group in New York City. His first play, *The Connection*, is historically important for its disintegration of the traditional relationship between audience and actor; it was a breakthrough for The Living Theatre, and both the production and the playwright received wide notice.

Set in a slum apartment, the play was staged to suggest a naturalistic scene, with actors already on stage as the audience arrived (as if the audience were seeing life, not a play, in progress). This nontraditional technique was supported by other subversive techniques: by presenting an actor as an audience member; by using the theatre aisles as a performance area; and by having the actors (who represented drug addicts) panhandle the audience during the play's intermission. The play was imaginatively and brilliantly produced by The Living Theatre, though, for all its appearance of improvisation, it was tightly structured.

*The Apple* (1961), Gelber's second play, also was written expressly for The Living Theatre. Its subject is the growing madness of an actor during a play rehearsal. With its second act written from the mad actor's point of view, this play, too, broke with the conventions of theatre. Less successful than its predecessor, *The Apple* had a run of 69 performances. Upon the departure of The Living Theatre for Europe, however, Gelber lost a performance group ideally suited to his drama.

His *Square in the Eye* (1965), a multimedia theatre piece, and the rest of his later plays—including *The Cuban Thing* (1968), *Sleep* (1972), and *Rehearsal* (1976)—continued to challenge theatrical conventions, though none matched the popular or critical success of his first play. Gelber also taught drama at several American colleges and universities and wrote the novel *On Ice* (1964).

**Gelder, Aert de**, Aert also spelled ARENT (b. Oct. 26, 1645, Dordrecht, United Provinces [now The Netherlands]—d. Aug. 28, 1727, Dordrecht), the only Dutch artist of the late 17th and early 18th century to paint in the tradition of Rembrandt's late style.

De Gelder spent his life in Dordrecht, except

"The Artist Painting a Portrait of an Old Woman," painting on canvas by Aert de Gelder, 1685; in the Städtisches Kunstinstitut, Frankfurt-am-Main

By courtesy of the Städtisches Kunstinstitut, Frankfurt-am-Main

for a period of time in about 1661 when he was Rembrandt's pupil in Amsterdam. His biblical paintings—*e.g.*, "Scenes from the Passion" (c. 1715)—feature warm colour and atmospheric light. In his portraits—*e.g.*, "The Family of Herman Boerhave" (c. 1722; Louvre, Paris)—his bold, broad manner of brushwork and surface texture contrasts markedly with the refined techniques and smoothly finished canvases of his contemporaries.

**Gelderland**, also called GUELDERS, *provincie*, eastern and central Netherlands. It occupies an area (1,935 square miles [5,011 square km]) extending from the German border westward to the narrow Lake Veluwe (separating Gelderland from several polders of Flevoland province) between the provinces of Overijssel (north) and Noordbrabant, Zuidholland, and Utrecht (south). Its capital is Arnhem.

The province's history began with the countship of Gelre, or Geldern, established in the 11th century around castles near Roermond and Geldern (now in Germany). The counts of Gelre acquired the Betuwe and Veluwe regions and, through marriage, the countship of Zutphen. This laid the foundation for a territorial power that, through control of the Rhine, Waal, Meuse, and IJssel rivers, was to play an important role in the later Middle Ages. The geographical position of their territory dictated the external policy of the counts: they were committed to the interests of the Holy Roman Empire and to expansion south and west. Further enlarged by the acquisition of the imperial city of Nijmegen in the 13th century, the countship was raised to a duchy in 1339 by the German king, Louis the Bavarian. After 1379 the duchy was ruled from Jülich and by the counts of Egmond and Cleves. The duchy resisted Burgundian domination, but William the Rich (duke of Jülich, Cleves, and Berg) was forced to cede it to Charles V in 1543, after which it formed part of the Burgundian-Habsburg hereditary lands. The duchy revolted with the rest of the Netherlands against Philip II of Spain and joined the Union of Utrecht (1579). After the deposition of Philip II, its sovereignty was vested in the "estates" of Gelderland, and the princes of Orange were stadholders. In 1672 it was temporarily occupied by Louis XIV; and in 1713 the southeastern part, including the ducal capital of Geldern, fell to Prussia. Successively part of the Batavian Republic (1795–1806), Louis Bonaparte's kingdom of Holland (1806–10), and the French Empire (1810–13), Gelderland became a province of the Kingdom of The Netherlands in 1815.

Gelderland is divided by the Lower Rhine (Neder Rijn) and the Oude ("Old") IJssel rivers. The main portion north of this line is a formerly glaciated region with sandy soil; south is fertile clay alluvium. The northern portion is divided by the broad valley (Gelderse) of the IJssel into the Veluwe ("Bad Land") region on the west and the Achterhoek on the

east. The hill plateau of the Veluwe is covered with scantily cultivated heaths and some woods, primarily fir and beech. There are two national parks (Hoge Veluwe and Veluwezoom) and a wildlife reserve. Much of the Veluwe is used for military purposes. In the south, the hills slope steeply along the Rhine, and the wooded part is residential, with some industry around Arnhem. The other large centre of the Veluwe is Apeldoorn along the eastern border. The Achterhoek is a well-watered and wooded pasture region supporting mixed farming, with dairy processing, meatpacking, and leather factories. The eastern part has textile works, and several foundries lie along the Oude IJssel. Zutphen and Doetinchem are the chief markets and have some industries. The valley of the IJssel, the Gelderse Valley (on the west along the Utrecht border), and the northern border of the Veluwe support mixed farming, especially poultry.

The southern division of the province is watered by the Rhine, Waal, and Maas (Meuse) rivers. In the east are some isolated hills and a sandy, wooded stretch south of Nijmegen, the province's largest town. The fertile marshy area of the Betuwe ("Good Land"), between the Rhine and the Waal, supports orchards (cherries and apples), market gardening, and mixed farming. Pop. (2003 est.) 1,960,384.

**gelechiid moth**, any member of the large, cosmopolitan insect family Gelechiidae (order Lepidoptera), containing more than 3,700 described species of moths, including several important pests. The brown adults have gray or silver markings and average 19 mm (¾ inch) in wingspan. The hindwings have somewhat concave outer margins and pointed tips, in contrast with the regular, narrow forewings.

The larval habits of gelechiid moths vary; larvae may mine or bore in plants, spin webs, form galls, or roll leaves. They are pale and naked and pupate within silken cocoons.

The whitish larvae of the Angoumois grain moth (*Sitotroga cerealella*) attack stored and growing grains, hollowing out the insides of kernels. The gray-coloured adult has blackish spots and a wing span of about 12 mm (about ½ inch).

The pink bollworm (*Pectinophora gossypiella*), deemed one of the most destructive insects, is a serious cotton pest. Though probably native to India, it is now distributed worldwide. It bores into cotton bolls, devouring blossoms and seeds. The pinkish-coloured bollworm generally pupates in a cocoon inside a boll or seed, in trash, or underground. The brown adult has fringed wings. In warm climates several generations occur annually.

The potato tuberworm (*Gnorimoschema operculella*) attacks potatoes, tomatoes, tobacco, and related plants, boring into tubers, burrowing in stems, and mining leaves. Pupation occurs in silken, dirt-covered cocoons, often found in rubbish. The adults are a dark mottled grayish brown.

The peach twig borer (*Anarsia lineatella*) attacks fruit trees. Less destructive gelechiid pests include the tomato pinworm (*Keiferia lycopersicella*) and the strawberry crown miner (*Aristotelia fragariae*). Several *Gnorimoschema* species produce galls in goldenrod stems, and many *Recurvaria* species mine leaves and pine needles.

**Gelfand, Aleksandr Izrail Lazarevich:** *see* Helphand, Alexander Israel (Lazarevitch).

**Gelfond, Aleksandr Osipovich** (b. Oct. 24, 1906, St. Petersburg, Russia—d. Nov. 7, 1968, Moscow), Russian mathematician who originated basic techniques in the study of transcendental numbers (numbers that cannot be expressed as the root or solution of an algebraic equation with rational coefficients). He profoundly advanced transcendental-number theory and the theory of interpolation and approximation of complex-variable functions.

Gelfond taught mathematics at the Moscow Technological College (1929–30) and, from 1931, at Moscow State University, at various times holding chairs of analysis, theory of numbers, and history of mathematics.

In 1934 Gelfond proved that  $a^b$  is transcendental if  $a$  is an algebraic number not equal to 0 or 1, and if  $b$  is an irrational algebraic number. This statement, now known as Gelfond's theorem, solved the seventh of 23 famous problems that had been posed by the German mathematician David Hilbert in 1900. Gelfond's methods were readily accepted by other mathematicians and rapidly developed important new concepts in transcendental-number theory. Much of his work, including the construction of new classes of transcendental numbers, is found in his *Transcendentnye i algebraicheskie chisla* (1952; *Transcendental and Algebraic Numbers*). In *Ischislenie konechnykh raznostey* (1952; "Calculus of Finite Differences"), he summarized his approximation and interpolation studies.

**Gelimer** (fl. early 6th century), last Vandal king (ruled 530–534) of the area called by the Romans "Africa" (roughly, modern Tunisia).

The great-grandson of the Vandal leader Gaiseric (ruled 428–477), Gelimer deposed King Hilderic, his pro-Roman cousin, in 530 and usurped the throne despite protests from the Eastern Roman emperor Justinian I. In June 533, Justinian sent an expeditionary force commanded by Belisarius against him. Landing in Africa in September 533, the Byzantines defeated Gelimer's army at Decimum, near Carthage, and occupied the city. As a result of his tactical blunders, Gelimer was decisively defeated (mid-December 533). He fled to Numidia, near the edge of the Sahara, but was forced to surrender in March 534. Thus the Vandal kingdom was destroyed and Roman rule returned to Africa. After the defeat Gelimer was sent to Constantinople, and Justinian gave him an estate in Galatia.

**Gell-Mann, Murray** (b. Sept. 15, 1929, New York City), American physicist, winner of the Nobel Prize for Physics for 1969 for his work pertaining to the classification of subatomic particles and their interactions.

Having entered Yale University at the age of 15, Gell-Mann received his B.S. in physics in 1948 and his Ph.D. at the Massachusetts Institute of Technology in 1951. His doctoral research on subatomic particles was influential in the later work of the Nobel laureate (1963) Eugene P. Wigner. In 1952 Gell-Mann joined the Institute for Nuclear Studies at the University of Chicago. The following year he introduced the concept of "strangeness," a quantum property that accounted for previously puzzling decay patterns of certain mesons. As defined by Gell-Mann, strangeness is conserved when any subatomic particle interacts via the strong force—i.e., the force that binds the components of the atomic nucleus.

In 1962 Gell-Mann and Yuval Ne'eman, an Israeli theoretical physicist, proposed a scheme for classifying previously discovered strongly interacting particles into a simple, orderly arrangement of families. Called the Eightfold Way (after Buddha's Eightfold Path to Enlightenment and bliss), the scheme grouped mesons and baryons (e.g., protons and neutrons) into multiplets of 1, 8, 10, or 27 members on the basis of various properties. All particles in the same multiplet are to be thought of as variant states of the same basic particle. Gell-Mann speculated that it should be possible to explain certain properties of known particles in terms of even more fundamental particles, or building blocks. He later called these basic bits of matter "quarks," adopting the fanciful term from James Joyce's novel *Finnegans Wake*. One of the early successes of Gell-Mann's quark hypothesis was the prediction and subsequent discovery of the omega-minus particle (1964). Over the years,

research has yielded other findings that have led to the wide acceptance and elaboration of the quark concept (see also quark).

Gell-Mann joined the faculty of the California Institute of Technology, Pasadena, in 1955 and was appointed Millikan Professor of Theoretical Physics in 1967 (emeritus, 1993). He published a number of works, notable among which are *The Eightfold Way* (1964), written in collaboration with Ne'eman, and *Broken Scale Variance and the Light Cone* (1971), coauthored with K. Wilson.

**Gellée, Claude** (painter): see Claude Lorrain.

**Gellert**, in Welsh tradition, the trusted hound of Prince Llewellyn the Great of Wales. Having been left to guard his master's infant son, Gellert killed a wolf that attempted to attack the child. Llewellyn, returning home to find the baby missing and Gellert's muzzle stained with blood, assumed that the dog had destroyed his son, and stabbed it. He later found the child unharmed beneath the overturned cradle, with the wolf's corpse beside him. The remorseful prince caused Gellert to be honourably buried on Mt. Snowden, and he named the place *Beddgelert* (Grave of Gellert).

The story, associated now with the historical Prince Llewellyn, is a late Welsh version of an ancient Indian folktale recounted in the Sanskrit *Pañca-tantra*. The legend is found in various forms in many European countries. It also exists in the Persian, Hebrew, and Buddhist traditions.

**Gellert, Christian Fürchtegott** (b. July 4, 1715, Hainchen, Saxony—d. Dec. 13, 1769, Leipzig), poet and novelist, a prominent representative of the German Enlightenment whose works were, for a time, second in popularity only to the Bible.

Gellert, lithograph  
Historia-Photo

The son of a pastor, Gellert was reared in a poor and extremely pious family. After working as a tutor, he studied at the University of Leipzig, where he became a *Privatdozent* (unsalaried lecturer) in 1745 and a professor in 1751. Popular both for his work and for his personality, his lectures on poetry, rhetoric, and ethics were exceptionally well attended.

Gellert was best known for his *Fabeln und Erzählungen* (1746–48; "Fables and Tales"), a collection of naively realistic fables and moralizing stories charming for their directness and simplicity. These tales not only had many readers among the common people but also influenced other fable writers. Equally popular was *Geistliche Oden und Lieder* (1757; "Spiritual Odes and Songs"), religious poems and hymns that combined religious feeling with the rationalism of the Enlightenment. The most famous of these, "Die Himmel rühmen den Ewigen Ehren" ("The Heavens Praise the Eternal Glories") and "Die Ehre Gottes aus der Natur" ("The Glory of God in Nature"), were later set to music by Beethoven and still appear in hymn books. Gellert also wrote a sentimental novel, *Das Leben der schwedische Gräfin von G* (1748; "The Life of the Swedish Countess of G"), which combined the late 17th-century novel of exotic adventure with

the character novel of modern literature and introduced the moralistic "family novel" in German literature.

**Gelligaer**, community, formerly known for mining, Caerphilly county borough, historic county of Glamorgan (Morgannwg), Wales, lying in the middle of the River Rhymney valley. Old Gelligaer village is located on the site of a Roman fort, on the ridge-top road northward from Cardiff, but the main settlements of the community, chief among them Bargoed, are villages in the river valley. Some light industry has been established since 1945, but the closing of the last coal mines during the late 20th century brought economic hardship. The locality contains the 8th-century Church of St. Cattwg and the 16th-century manor house of Llancaiach. Pop. (1991), 15,906.

**Gellius, Aulus** (fl. 2nd century AD), Latin author remembered for his miscellany *Noctes Atticae* ("Attic Nights"), in which many fragments of lost works are preserved. Written in Athens to beguile the winter evenings, the work is an interesting source on the state of knowledge and scholarship of his time. Both in Rome, where he studied literature and rhetoric, and in Athens, where he studied philosophy, Gellius' teachers and friends included many distinguished men, anecdotes about whom he included in his book.

**Gelmírez, Diego** (b. c. 1068—d. c. 1139), Spanish bishop and archbishop of Santiago de Compostela, site of the supposed shrine of St. James, which he developed as a place of pilgrimage.

Gelmírez was consecrated bishop of Compostela in 1101, and in 1120 Pope Calixtus II promoted him to archbishop and appointed him papal legate in Spain. Gelmírez' ambition involved him both in bitter ecclesiastical quarrels and in the civil strife which characterized the minority of Alfonso VII of Castile. On several occasions he narrowly escaped death at the hands of the queen mother Urraca or the burgesses of Santiago, who found him a tyrannical overlord.

Gelmírez did much to develop the reputation of Santiago as a pilgrim shrine, his own wealth and influence being based on it. He reformed what had previously been a lax diocese and, at the Council of Compostela (1124), caused the Peace and Truce of God to be proclaimed for the first time in Castile. In civil war he showed himself to be a competent military commander; and, to defeat Moorish naval attacks on Galicia, he organized a small fleet—the first in medieval Castile. Gelmírez' inordinate desire to extend his power, however, caused Honorius II, the successor of Calixtus II (d. 1124), to deprive him of his legateship and incurred the distrust of his former protégé, Alfonso VII, who managed, by devious methods, to lay hands on some of Gelmírez' great wealth. His influence had, therefore, considerably declined when he died.

**Gelon** (b. c. 540 BC—d. 478), tyrant of the cities of Gela (491–485) and Syracuse (485–478) in Sicily.

On the death of Hippocrates, the tyrant of Gela, in 491, Gelon, who had been his cavalry commander, succeeded him. Gelon early became involved in inconclusive hostilities with Carthage. In 485, taking advantage of an appeal by the *gamoroi* (conservative landowners) of Syracuse, who had been driven out by the people, he made himself master of that city, leaving his brother Hieron to control Gela. Under Gelon, Syracuse grew rapidly in population and power. Mercenaries were recruited widely, and a strong fleet was built up. Gelon conquered the nearby Sicilian cities of Euboea and Megara Hyblaea (c. 483), selling

their common people into slavery and bringing their oligarchs to Syracuse. He controlled the Greek and Sicel communities of east Sicily and became linked by marriage with Theron, tyrant of Acragas (later the Roman Agrigentum, modern Agrigento). When the Carthaginians invaded Sicily in 480, Theron appealed to Gelon, who was primarily responsible for the decisive Greek victory of Himera.

**Gelosi, Compagnia dei** (Italian: "Company of Jealous Ones"), one of the earliest and most

Commedia dell'arte troupe, probably depicting Isabella Andreini and the Compagnia dei Gelosi, oil painting by unknown artist, c. 1580; in the Musée Carnavalet, Paris

CFL—Giraoudon from Art Resource/EB Inc

famous of the commedia dell'arte companies of 16th-century Italy. The name was derived from the troupe's motto, *Virtù, fama ed honore fèr gelosi* ("We are jealous of attaining virtue, fame, and honour").

Formed in Milan c. 1568 under the leadership of Flaminio Scala, the Gelosi became highly popular throughout Italy. Their group was the first to be patronized by nobility, and in 1574 they were invited to perform before the visiting French king, Henry III, in Venice. Their fame spread abroad, and they were asked by King Henry to perform before his court in 1577. Thereafter the Gelosi carried the tradition and influence of the commedia all over Europe, playing in France, Poland, Spain, and Germany. They established a habit of touring that was quickly followed by other Italian companies. The star performers were Francesco Andreini, a scholarly and talented actor who specialized in the roles of Capitano and Dottore, and his wife, Isabella, who was one of the leading belles and most famous actresses of the age (see Andreini, Francesco; Andreini, Isabella). After her death in 1604 the company was dissolved.

**Gelsenkirchen**, city, North Rhine-Westphalia *Land* (state), western Germany, just north of Essen. It was a village of fewer than 1,000 inhabitants in 1850, but the opening of its first coal mine (1853) and its favourable position on the Rhine-Herne Canal stimulated Gelsenkirchen's rapid development as a Ruhr inland port and industrial centre. It was chartered in 1875 and absorbed the neighbouring towns of Buer and Horst in 1928. Buer, north of the Emscher River, which bisects the city, is surrounded by a 1,000-acre (400-hectare) greenbelt. The moated castles of Schloss Berge, Schloss Horst (restored Baroque), and Haus Lüttinghof survived the heavy bombings, which caused widespread destruction, during World War II.

Located in one of the largest coal-mining and coking areas of Germany, Gelsenkirchen is dominated by heavy industry, producing iron, steel, chemicals, glass, and clothing. Pop. (1989 est.) 287,255.

**Geltzer, Yekaterina Vasilyevna** (b. Nov. 14 [Nov. 2, old style], 1876, Moscow—d. Dec. 12, 1962, Moscow), prima ballerina of the Moscow Bolshoi Theatre who, during the period of disorder following the Revolution of 1917, helped preserve and pass on the classical technique and repertory of the Imperial Russian Ballet.

Though her father, Vasily Geltzer, an outstanding mime dancer and regisseur of the Bolshoi Theatre, believed her physique was unsuitable for dancing, Yekaterina persuaded him to enroll her at eight in the Bolshoi's ballet school. There she developed strong pointe

and pirouette technique under her teacher Joseph Mendes and graduated in 1894. After two years with the Bolshoi company, she went to St. Petersburg to study with Christian Johansson, who helped her attain the elegant grace that earned her the title "queen of adagio." In 1901 she became prima ballerina. Though she danced in most of the classic ballets at the Bolshoi, including *Swan Lake*, *The Sleeping Beauty*, and *Coppélia*, she excelled in dramatic roles and in the so-called *demi-caractère* style of dance, in which classical ballet technique is used to perform character dance. She also performed in Paris (1910) with the Diaghilev company and in London (1911)

Yekaterina Geltzer, 1912

with the famous Russian dancer and teacher Vasilii Tikhomirov, whom she later married.

After the Revolution of 1917, Geltzer remained with the Moscow company, and in 1927 she created one of her most famous roles, that of Tao-Hoa, the self-sacrificing heroine of *The Red Poppy* who dies to save the life of a Soviet captain. Her career at the Bolshoi spanned more than 40 years, and she was one of the first to receive (1925) the title People's Artist of the Russian Soviet Federated Socialist Republic.

**Gelukpa** (Buddhist sect): see Dge-lugs-pa.

**gem**: see gemstone.

**Gemara**, a rabbinic commentary on and interpretation of the collection of Jewish law known as the Mishna. See Talmud.

**gematria**, the substitution of numbers for letters of the Hebrew alphabet, a favourite method of exegesis used by medieval Kabbalists to derive mystical insights into sacred writings or obtain new interpretations of the texts. Some condemned its use as mere toying with numbers, but others considered it a useful tool, especially when difficult or ambiguous texts otherwise failed to yield satisfactory analysis. Genesis 28:12, for example, relates that in a dream Jacob saw a ladder (Hebrew *sullam*) stretching from earth to heaven. Since the numerical value of the word *sullam* is 130 (60 + 30 + 40)—the same numerical value of Sinai (60 + 10 + 50 + 10)—exegetes concluded that the Law revealed to Moses on Mount Sinai is man's means of reaching heaven. Of the 22 letters in the Hebrew alphabet, the first ten are given number values consecutively from one to ten, the next eight from 20 to 90 in intervals of ten, while the final four letters equal 100, 200, 300, and 400, respectively. More complicated methods have been used, such as employing the squares of numbers or making a letter equivalent to its basic value plus all numbers preceding it.

**Gemayel FAMILY**, Maronite Christian family prominent in Lebanese politics before and after the start of that country's civil war in 1975.

Pierre Gemayel (b. Nov. 1/6, 1905, Bikfaya?, Leb.—d. Aug. 29, 1984, Bikfaya) was born into a Christian family already powerful in the region immediately north of Beirut. He attended St. Joseph University in Beirut and trained as a pharmacist. On a visit to Berlin to attend the 1936 Olympic Games, he was so impressed by the spirit and discipline of Nazi youth groups that on his return to Lebanon he helped found the right-wing authoritarian youth movement called the Phalange. He became the leader of the Phalange Party in 1937, retaining that position until 1980. This party became the political arm of the largest Christian community in Lebanon, the Maronites. Pierre was first elected to the Lebanese Parliament in 1960 and held several Cabinet posts during the 1960s. He ran unsuccessfully for the presidency (which was traditionally held by a Christian) in 1964 and 1970. When the civil war broke out in 1975, Gemayel led the powerful Phalangist militia in their clashes with Lebanese Muslims and Palestinian fighters. He was instrumental in creating a large, militarily secure Christian enclave north of Beirut and became Lebanon's preeminent Christian political chieftain.

Pierre's youngest son, Bashir Gemayel (b. Nov. 10, 1947, Bikfaya—d. Sept. 14, 1982, Beirut), emerged during the fighting of the late 1970s as the able and ruthless leader of the Phalangist militia. Bashir unified the military forces of the Maronite community in 1980 after launching several murderous surprise attacks on rival Christian militias. He formally took over control of the Phalangist Party from his father in 1980. Bashir was elected president of Lebanon by the Parliament in August

1982 in the face of opposition by many of the country's Muslims, who disliked his close association with sectarian violence. Bashir was assassinated in a bomb explosion 10 days before he was due to take office.

Bashir's older brother, Amin Gemayel (b. 1942, Bikfaya), was elected president of Lebanon a week after Bashir died. In contrast to his warlike brother, Amin had shown himself to be conciliatory toward the other religious groups in Lebanon during his 12 years as a member of the Lebanese Parliament (1970–82). He had been trained as a lawyer and had overseen the Phalangist Party's vast business interests while Bashir led the party's militia. As president, however, the ineffective Amin proved no more successful than his predecessors in securing an agreement between Lebanon's warring groups that would end the country's civil war.

**Gemeinschaft and Gesellschaft**, ideal types of social organizations that were systematically elaborated by the German sociologist Ferdinand Tönnies in his influential work *Gemeinschaft und Gesellschaft* (1887; *Community and Society*).

Tönnies' conception of the nature of social systems is based on his distinction between the *Gemeinschaft* (communal society) and the *Gesellschaft* (associational society). In the rural, peasant societies that typify the *Gemeinschaft*, personal relationships are defined and regulated on the basis of traditional social rules. People have simple and direct face-to-face relations with each other that are determined by *Wesenwille* (natural will)—i.e., natural and spontaneously arising emotions and expressions of sentiment.

The *Gesellschaft*, in contrast, is the creation of *Kürwille* (rational will) and is typified by modern, cosmopolitan societies with their government bureaucracies and large industrial organizations. In the *Gesellschaft* rational self-interest and calculating conduct act to weaken the traditional bonds of family, kinship, and religion that permeate the *Gemeinschaft*'s structure. In the *Gesellschaft* human relations are more impersonal and indirect, being rationally constructed to serve efficiency or other economic and political considerations.

The alienation and the breakdown of cohesive peasant values attending the rise of industrialization caused many disenchanted intellectuals to romanticize the *Gemeinschaft* after World War I. This misuse of Tönnies' dichotomy constituted a failure to understand that *Gemeinschaft* and *Gesellschaft* were ideal types and not categories of classification.

**gemilut hessed** (Hebrew: "bestowing kindness"), also called *GEMILUT HASADIM* ("bestowing kindnesses"), in Judaism, an attribute of God said to be imitated by those who in any of countless ways show personal kindness toward others. A Jew who does not manifest sensitive concern for others is considered no better than an atheist, regardless of his knowledge of the Torah. Although emphasis is on personal service rather than on money, many *gemilut hessed* societies have been organized to lend money without interest to those temporarily in need, an act of kindness considered superior to almsgiving because a loan does not humiliate the recipient.

**Gemini** (Latin: "Twins"), in astronomy, zodiacal constellation lying between Cancer and Taurus, at about 7 hours right ascension (the coordinate of the celestial sphere analogous to longitude on the Earth) and 22° north declination (angular distance north of the celestial equator). Its brightest stars are Castor and Pollux (Alpha and Beta Geminorum), Pollux being the brighter of the two. The summer solstice, the northernmost point reached by the Sun in its annual apparent journey among the stars, lies in Gemini.

In astrology, Gemini is the third sign of the

Gemini, illumination from a Book of Hours, Italian, c. 1475; in the Pierpont Morgan Library, New York City (MS. G.14)

By courtesy of the Pierpont Morgan Library, New York. The Glazier Collection

zodiac, considered as governing the period c. May 21–c. June 21. It is represented by a set of twins (in Egyptian astrology by a pair of goats and in Arabian astrology by a pair of peacocks). In addition to their identification as Castor and Pollux, the twins have also been related to other celebrated pairs, such as the younger and older Horus, or Romulus and Remus.

**Gemini**, any of a series of 12 two-man spacecraft launched into orbit around the Earth by the United States between 1964 and 1967. The Gemini (Latin: "Twins") program was preceded by the Mercury series of one-man spacecraft and was followed by the Apollo series of three-man spacecraft. The Gemini program was chiefly designed to test the ability of astronauts to maneuver their spacecraft by means of manual control. The Gemini series, directed by the National Aeronautics and Space Administration (NASA), helped to develop the techniques for orbital rendezvous and docking with a target vehicle, procedures that were vital to the subsequent Apollo Moon-landing program. It also provided NASA engineers with an opportunity to improve environmental control and electrical power systems of spacecraft. During the Gemini 4 mission (launched June 3, 1965), astronaut Edward H. White practiced maneuvering outside the spacecraft for 20 minutes, demonstrating man's increasing ability to function in space. Gemini 5 (Aug. 21, 1965) completed an eight-day mission, the longest space flight undertaken up to that time. Gemini 12 (Nov. 11, 1966), the last in the series, made the first automatically controlled reentry into the Earth's atmosphere.

**Geminiani, Francesco** (baptized Dec. 5, 1687, Lucca, Tuscany—d. Sept. 17, 1762, Dublin), Italian composer, violinist, writer on musical performance, and a leading figure in early 18th-century music.

Geminiani may have studied under Corelli. He established his reputation as a brilliant performer in England, publishing (1716) his Opus 1 sonatas for violin and continuo, which were famous for their technical difficulty and were widely acclaimed as equal to Corelli's. His other popular works include concerti grossi, of which his Opus 2 and Opus 3 sets became extremely popular in England, holding a place in the popular repertoire well into the next century. His theoretical writings, particularly *The Art of Playing on the Violin* (1730), had considerable influence, and the latter work remains an important reference on the performance of late Baroque music.

**Gemistus Plethon, George**, Plethon also spelled PLETHO (b. c. 1355, Constantinople—d. 1450/52, Mistra, Morea), Byzantine

philosopher and humanist scholar whose clarification of the distinction between Platonic and Aristotelian thought proved to be a seminal influence in determining the philosophic orientation of the Italian Renaissance.

Plethon studied in Constantinople and at the Ottoman Muslim court in nearby Adrianople. He founded a school of esoteric religious philosophy at Mistra, an important citadel in the Peloponnese, where he spent much of the rest of his life. He served as a consultant and composed proposals on social and governmental reform for the emperors Manuel II Palaeologus (reigned 1391–1425) and John VIII Palaeologus (1425–48). Most importantly, Plethon served as lay theologian with the Byzantine delegation to the 1438–45 general Council of Ferrara–Florence, which had been convened to reunite the Latin and Greek churches confronted by the rapid encroachment of the Ottoman Turks upon Constantinople.

Concerned more with the advancement of Neoplatonic philosophy than with religious questions, Plethon delivered to the Florentine humanists at the Council of Ferrara–Florence his treatise "On the Difference Between Aristotle and Plato." This work fired the humanists with a new interest in Plato (who had been ignored in the West during the Middle Ages because of the preoccupation with Aristotle) and inspired Cosimo de' Medici with the project of founding the Platonic Academy of Florence. Plethon also introduced the *Geography* of Strabo to the West (where it had hitherto been unknown) and led the way to the overthrow of Ptolemy's erroneous geographical theories. He thus greatly affected the Renaissance conception of the configuration of the Earth and so played an important, if indirect, role in the discovery of America by Christopher Columbus, who cited Strabo among his principal authorities.

On returning to the Peloponnese, Plethon wrote his "Code of Laws," evocative of Plato's *Laws*, in which he set forth a social and political utopia modeled on classic Athenian culture and integrating with it elements of Platonism, Stoicism, Islamic fatalism, and emperor worship. Plethon also composed orations and essays on Zoroaster, astronomy, music, history, rhetoric, and various theological subjects. Nearly all of his writing is marked by passionate devotion to Greece and a desire to restore its ancient glory.

**Gemma Augustea** (Latin: "Gem of Augustus"), sardonyx cameo depicting the apotheosis of Augustus. He is seated next to the goddess Roma, and both are trampling the armour of defeated enemies. It is one of the most impressive carved cameos of a series of Roman gems representing imperial persons. The Gemma Augustea (now in the Kunsthistorisches Mu-

Gemma Augustea, Roman sardonyx cameo, late 1st century bc; in the Kunsthistorisches Museum, Vienna

By courtesy of the Kunsthistorisches Museum, Vienna

seum, Vienna) was probably carved during the reign of Caligula (AD 37–41). Others in the series include the Grand Camée de France and the Blacas onyx cameo in the British Museum, London.

**gemmail**, plural **GEMMAUX**, in stained glass, technique employing fused layers of coloured glass fragments illuminated from behind, creating an illusion of three-dimensionality in the design. *Gemmail* is frequently used to reproduce works from other pictorial media. The

technique was developed in the late 1930s by the French artist Jean Crotti.

A *gemmail* is constructed, piece by piece, on a pane of clear glass bearing the outline of the design. When all fragments have been glued in place, the work is dipped in transparent enamel and baked until fused. Works by Picasso, Braque, and Rouault have been reproduced in this medium, and the Franklin D. Roosevelt station of the Paris metro is decorated with a series of *gemmaux*.

**Gempei War** (1180–85), final struggle in Japan between the Taira and Minamoto clans that resulted in the Minamoto's establishment

of the Kamakura shogunate, a military dictatorship that dominated Japan from 1192 to 1333.

The Taira clan had dominated the Imperial government from 1160 to 1185. Minamoto Yoritomo, the son of the great Minamoto leader Yoshitomo, had been spared after his father's defeat in 1160 because of his youth. Now an adult, he capitalized on the growing dissent with Taira leadership on behalf of members of both the Taira and Minamoto families and organized a new revolt in 1180. He soon gained control of the strategic east coast of Japan and by 1182 was ready to

advance on the capital at Kyōto. The Taira leaders fled, taking with them the infant emperor Antoku. In the sea battle of Dannoura (1185) on the Inland Sea in western Japan, the Taira were finally defeated. The emperor Antoku was drowned in the battle, losing a famous sword, one of the Imperial Treasures of Japan supposedly brought from heaven by the first Japanese emperor. The battle became legendary through accounts such as the *Gempei seisui-ki* ("Record of the Rise and Fall of the Minamoto and Taira").

**gemsbok**, African hoofed mammal, a subspecies of oryx (*q.v.*).

**gemstone**, any of various minerals highly prized for beauty, durability, and rarity. A few noncrystalline materials of organic origin (*e.g.*, pearl, red coral, and amber) also are classified as gemstones.

Gemstones have attracted humankind since ancient times, and have long been used for jewelry. The prime requisite for a gem is that it must be beautiful. The beauty may lie in colour or lack of colour; in the latter case, extreme limpidity and "fire" may provide the attraction. Iridescence, opalescence, asterism (the exhibition of a star-shaped figure in reflected light), chatoyance (the exhibition of a changeable lustre and a narrow, undulat-

ing band of white light), pattern, and lustre are other features that may make a gemstone beautiful. A gem must also be durable, if the stone is to retain the polish applied to it and withstand the wear and tear of constant handling.

In addition to their use as jewelry, gems were regarded by many civilizations as miraculous and endowed with mysterious powers. Different stones were endowed with different and sometimes overlapping attributes; the diamond, for instance, was thought to give its

\*Properties given here are for gem-quality material, and hence may differ from those of the mineral.

wearer strength in battle and to protect him against ghosts and magic. Vestiges of such beliefs persist in the modern practice of wearing a birthstone.

Of the more than 2,000 identified natural minerals, fewer than 100 are used as gemstones and only 16 have achieved importance. These are beryl, chrysoberyl, corundum, diamond, feldspar, garnet, jade, lazurite, olivine, opal, quartz, spinel, topaz, tourmaline, turquoise, and zircon. Some of these minerals provide more than one type of gem; beryl, for example, provides emeralds and aquamarines, while corundum provides rubies and sapphires. In virtually all cases, the minerals have to be cut and polished for use in jewelry.

Except for diamond, which presents special problems because of its very great hardness (see diamond cutting), gemstones are cut and polished in any of three ways. Agate, opal, jasper, onyx, chalcedony (all with a Mohs hardness of 7 or less) may be tumbled; that is, they may be placed in a cylinder with abrasive grit and water and the cylinder rotated about its long axis. The stones become polished but are irregular in shape. Second, the same kinds of gemstones may instead be cut *en cabochon* (i.e., with a rounded upper surface and a flat underside) and polished on water- or motor-driven sandstone wheels. Third, gemstones with Mohs hardness of more than 7 may be cut with a carborundum saw and then mounted in a holder (dop) and pressed against a lathe that can be made to revolve with extreme rapidity. The lathe carries a point or small disk of soft iron, which can vary in diameter from that of a pinhead to a quarter of an inch. The face of the disk is charged with carborundum grit, diamond dust, or other abrasives, along with oil. Another tool used to grind facets is the dental engine, which has greater flexibility and sensitiveness than the lathe. The facets are ground onto the stone using these tools and then are polished as described above.

Of decisive significance for the modern treatment of gemstones was the kind of cutting known as faceting, which produces brilliance by the refraction and reflection of light. Until the late European Middle Ages, gems of all kinds were simply cut either *en cabochon* or, especially for purposes of incrustation, into flat platelets.

The first attempts at cutting and faceting were aimed at improving the appearance of stones by covering natural flaws. Proper cutting depends on a detailed knowledge of the crystal structure of a stone, however. Moreover, it was only in the 15th century that the abrasive property of diamond was discovered and used (nothing else will cut diamond). After this discovery, the art of cutting and polishing diamonds and other gems was developed, probably in France and The Netherlands first. The rose cut was developed in the 17th century, and the brilliant cut, now the general favourite for diamonds, is said to have been used for the first time about 1700.

In modern gem cutting, the cabochon method continues to be used for opaque, translucent, and some transparent stones, such as opal, caruncle, and so on; but for most transparent gems (especially diamonds, sapphires, rubies, and emeralds), faceted cutting is almost always employed. In this method, numerous facets, geometrically disposed to bring out the beauty of light and colour to the best advantage, are cut. This is done at the sacrifice of material, often to the extent of half the stone or more, but the value of the gem is greatly increased. The four most common faceted forms are the brilliant cut, the step cut, the drop cut, and the rose cut.

In addition to uncut stones being cabochon cut, some are engraved. High-speed, diamond-tipped cutting tools are used. The stone

is hand-held against the tool, with the shape, symmetry, size, and depth of cut being determined by eye. Gemstones can also be made by cementing several smaller stones together to create one large jewel. See assembled gem.

In some cases, the colour of gemstones is also enhanced. This is accomplished by any of three methods: heating under controlled conditions, exposure to X rays or radium, or the application of pigment or coloured foil to the pavilion (base) facets.

In recent times various kinds of synthetic gems, including rubies, sapphires, and emeralds, have been produced. Two methods of fabrication are currently employed, one involving crystal growth from solution and the other crystal growth from melts.

**genale** (Ethiopia and Somalia): see Jubba River.

**Genç Osman** (Ottoman sultan): see Osman II.

**Genck** (Belgium): see Genk.

**gender**, in language, a phenomenon in which the words of a certain part of speech, usually nouns, require the agreement, or concord, through grammatical marking (or inflection), of various other words related to them in a sentence. In languages that exhibit gender, two or more classes of nouns control variation in words of other parts of speech (typically pronouns and adjectives and sometimes verbs). These other words maintain constant meaning but vary in form according to the class of the word that controls them in a given situation.

Among modern Indo-European languages such as French, Spanish, and Italian, nouns are classified into two genders, masculine and feminine. Russian and German nouns are grouped into three genders, the third being neuter. While nouns referring to masculine or feminine beings almost always take the logical gender in these languages, for most other nouns the gender is arbitrary.

In the following examples from French, the indefinite article and the adjective display a change in form depending on whether the noun that they modify is masculine (*poème*, "poem") or feminine (*pièce*, "play"); *un poème intéressant*, "an interesting poem," but *une pièce intéressante*, "an interesting play."

Swahili and many other languages have a gender system in which the relationship between the logical category of an object and its grammatical gender is specified to a much greater degree. Gender classes in such languages may include animate beings, inanimate objects, plants, animals, tools, and objects of a particular shape.

**gender identity**, an individual's self-conception as being male or female, as distinguished from actual biological sex. For most persons, gender identity and biological characteristics are the same. There are, however, circumstances in which an individual experiences little or no connection between sex and gender; in transsexualism, for example, biological sexual characteristics are distinct and unambiguous, but the affected person believes that he or she is—or ought to be—of the opposite sex (see transsexualism). Gender identity is not fixed at birth; both physiologic and social factors contribute to the early establishment of a core identity, which is modified and expanded by social factors as the child matures.

Basic gender identity—the concept "I am a boy" or "I am a girl"—is generally established by the time the child reaches the age of three and is extremely difficult to modify thereafter. In cases where biological sex was ambiguous at birth and errors in sexing were made, it has been almost impossible to reestablish the proper identity later in childhood or adolescence. Furthermore, a secondary gender identity can be developed over the core identity, as sex-associated behaviours may be adopted

later in life; heterosexual or homosexual orientations also develop later.

Like an individual's concept of his or her sex role, gender identity develops by means of parental example, social reinforcement, and language. Parents teach sex-appropriate behaviour to their children from an early age, and this behaviour is reinforced as the child grows older and enters a wider social world. As the child acquires language, he also learns very early the distinction between "he" and "she" and understands which pertains to him- or herself.

**gene**, unit of hereditary information that occupies a fixed position (locus) on a chromosome. Genes achieve their effects by directing the synthesis of proteins.

A brief treatment of genes follows. For full treatment, see MACROPAEDIA: Genetics and Heredity, The Principles of.

Genes are composed of deoxyribonucleic acid (DNA), except in some viruses, which have genes consisting of a closely related compound called ribonucleic acid (RNA). A DNA molecule is composed of two chains of nucleotides that wind about each other to resemble a twisted ladder. The sides of the ladder are made up of sugars and phosphates; the rungs are formed by bonded pairs of nitrogenous bases. These bases are adenine (A), guanine (G), cytosine (C), and thymine (T). An A on one chain bonds to a T on the other (thus forming an A–T ladder rung); similarly, a C on one chain bonds to a G on the other. If the bonds between the bases are broken, the two chains unwind, and free nucleotides within the cell attach themselves to the exposed bases of the now-separated chains. The free nucleotides line up along each chain according to the base-pairing rule—A's bond to T's, C's bond to G's. This process results in the creation of two identical DNA molecules from one original and is the method by which hereditary information is passed from one generation of cells to the next.

The sequence of bases along a strand of DNA determines the genetic code. When the product of a particular gene is needed, the portion of the DNA molecule that contains that gene will split. A strand of RNA with bases complementary to those of the gene is created from the free nucleotides in the cell. (RNA has the base uracil [U] instead of thymine, so A and U form base pairs during RNA synthesis.) This single chain of RNA, called messenger RNA (mRNA), then passes to the organelles called ribosomes, where protein synthesis takes place. A second type of RNA, transfer RNA (tRNA), matches up the nucleotides on mRNA with specific amino acids. Each set of three nucleotides codes for one amino acid. The series of amino acids built according to the sequence of nucleotides forms a polypeptide chain; all proteins are made from one or more linked polypeptide chains.

Experiments indicate that one gene is responsible for the assembly of one polypeptide chain. This is known as the one-gene-one-polypeptide hypothesis.

Other experiments have shown that many of the genes within a cell are inactive much or even all of the time. Thus, at any time, it seems that a gene can be switched on or off. The process by which genes are activated and deactivated in bacteria has been determined. Bacteria actually have three types of genes: structural, operator, and regulator. Structural genes code for the synthesis of specific polypeptides. Operator genes contain the code necessary to begin the process of transcribing the DNA message of one or more structural genes into mRNA. Thus, structural genes are linked to an operator gene in a functional unit called an operon. Ultimately, the activity of the operon is controlled by a regulator gene, which produces a small protein molecule

called a repressor. The repressor binds to the operator gene and prevents it from initiating the synthesis of the protein called for by the operon. The presence or absence of certain repressor molecules determines whether the operon is off or on. As was mentioned, this model applies to bacteria. Gene regulation in higher organisms is less clearly understood.

Mutations occur when the number or order of bases in a gene is disrupted. Nucleotides can be deleted, doubled, rearranged, or replaced, with each alteration having a particular effect. The mutation generally has little or no effect; when it does alter an organism, the change is frequently lethal. A beneficial mutation will rise in frequency within a population until it becomes the norm.

**gene flow**, also called **GENE MIGRATION**, the introduction of genetic material (by interbreeding) from one population of a species to another, thereby changing the composition of the gene pool of the receiving population. The introduction of new alleles through gene flow increases variability within the population and makes possible new combinations of traits. In human beings gene flow usually comes about through the actual migration of human populations, either voluntary or forced.

*Articles are alphabetized word by word,  
not letter by letter*

**genealogy**, the study of family origins and history. Genealogists compile lists of ancestors, which they arrange in pedigree charts. In forms varying from rudimentary to the comparatively complex, genealogy is found in all nations and periods.

A brief treatment of genealogy follows. For full treatment, see **MACROPAEDIA: History, The Study of**.

Genealogy is international in its scope and interest and, though now principally confined to European and American countries, has been studied in all civilized parts of the world. Wherever there has been a hereditary monarchy or aristocracy (e.g., China and Japan), genealogy has been a necessity as well as a pastime. In Muslim countries descent from the Prophet Muhammad and claims on the caliphate have always had a political as well as a religious significance. In non-Christian countries the frequent practice of polygamy, the legal status given to concubinage, and the habit of adoption (as in India) have added problems of their own.

Because genealogy is an international science, attempts have been made to secure a uniform system of signs and abbreviations for universal use in constructing pedigrees. The first International Congress of Heraldry and Genealogy, held in Barcelona in 1928, greatly helped to stimulate interest on a worldwide basis. Many countries now possess societies for promoting genealogical research, and some have even established university professorships in it.

The genealogist needs to have some knowledge of paleography, to help him decipher ancient records (e.g., parish registers and rolls, like the so-called Roll of Battle Abbey), and of chronology, so that he can recognize variations in the calendars and assess regnal years, etc. A knowledge of older languages such as Latin, as well as of the modern languages, is especially helpful. Old deeds, charters, seals, coins, medals, banners, tapestries (for example, the Bayeux tapestry), paintings, tombs, gravestones, and monumental tablets such as brasses may also provide valuable information.

Genealogy no longer concerns itself exclusively with the lineage of the highly placed but has an equal concern for all sorts and conditions of people. It furthermore possesses a genetic interest insofar as certain abilities and characteristics tend to repeat themselves in successive generations.

Oral traditions were of prime importance in the early days of civilization. Without written records, memory, along with such mnemonic devices as rhymes, was relied upon to provide a history. Genealogical information was orally transmitted most often as a list of names, as in the lineages of the ancient Irish kings. Sometimes outstanding events were also featured in such lists.

The long Oriental genealogies concern only great persons or princes. It is impossible to determine if the genealogies of the ancient families of India, which trace the descent of Indian princes from the earliest centuries, are fabricated because the genealogies are all that is known. In Africa another claim to a very long descent, that of the former emperor of Ethiopia, cannot be verified. The emperor was said to have descended from King Solomon's marriage to the Queen of Sheba; but, because this oral tradition was recorded over 15 centuries ago, there is no documentary proof.

The Old Testament contains many genealogies that have the purpose of showing descent from Adam, Noah, and Abraham. When these genealogies became part of the Jewish scriptures, the keeping of family records was reinforced by the concept of racial purity. Among the Gentiles, the idea of divine origin was manifested in the fables about heroes whose paternity was almost always ascribed to the gods. In Greek and Roman genealogies great men were usually begotten by gods or mortals that had become divine.

Early written family records originated in the ancient Mediterranean area, where the oral genealogies became poems and histories. But the invention of writing did not yet render genealogy a science. Writers dealt with genealogy either incidentally or out of concern with the lineage of their gods.

The recording of regal traditions began in the early Middle Ages. The first chroniclers were monks who documented the oral pedigrees of their kings. From approximately 1100 to 1500, genealogists concentrated on the pedigrees of noble and royal lines. Claims to a throne often involved genealogical trees, as when the death of Scotland's Alexander III in 1286 and of his direct heir, Margaret the Maid of Norway, in 1290 brought out a dozen claimants to the Scottish crown. Sometimes the truth was stretched for political purposes, but, in general, medieval European records are genealogically accurate. This is due to their primary purpose, which was to record land transactions, taxation, and lawsuits and not to provide genealogical information.

This period was also characterized by the appearance of pedigrees of common folk. Attention to pedigree became particularly important in the transition from serfdom to villenage, when a man would try to show that he was not a villein and the bailiff would try to prove that he was. It was only in the latest period in European genealogical history, from 1500 to the present, that records that included most ordinary people were begun. The emergence of a powerful mercantile and business community and the rise of the middle classes contributed to the proliferation of records. The Reformation's emphasis on individual religion and the Renaissance monarchs' desire for greater information about their subjects also led to the increased importance of keeping records and tracing ancestry.

In modern genealogy, professional genealogists are concerned with a large number of family histories and broad principles of genealogical research.

**genecentre**, also spelled **GENECENTER**, any of a number of areas on the Earth from which arose important crop plants and domestic animals. As few as four of these centres of origin have probably provided the great majority of the most useful plants and animals: (1) tropical southeastern Asia—rice, chickens; (2) temper-

ate southwestern Asia—wheat, sheep, goats, asses; (3) subtropical or temperate Mexico and Central America—corn (maize), turkeys; and (4) the central Andes of South America—potatoes, guinea pigs, llamas. Genecentres are associated historically with areas of fairly high population that were suitable for moderately intense agriculture.

**Genée, Dame Adeline**, original name **ANITA JENSEN** (b. Jan. 6, 1878, Arhus, Den.—d. April 23, 1970, Esher, Surrey, Eng.), ballerina whose classic style and precise technique were especially noteworthy during ballet's general decline in the years around 1900.

At eight she was adopted by her aunt and uncle, the dancers who trained her for the

Adeline Genée, c. 1900  
BBC Hulton Picture Library

ballet. Her early appearances were in Germany. From 1897 until 1907 she was prima ballerina at the Empire Theatre in London. Although her repertoire was extensive, she is most frequently associated with *Coppélia*, a ballet revived for her in 1906.

She made her U.S. debut in 1907 and during the following decade played five American seasons, mainly in musical revues. She retired from the stage in 1917 but continued to play an active part in English ballet, making occasional appearances until 1933 and serving as the first president, from 1920 until 1954, of the Association of Operatic Dancing of Great Britain (later the Royal Academy of Dancing). She was created Dame of the Order of the British Empire in 1950.

**Geneina Fort** (The Sudan): see **Junaynah Fort**, al-.

**Generación del Noventa y Ocho** (Spanish literature): see '98, Generation of.

**general**, title and rank of a senior army officer, usually one who commands units larger than a regiment or its equivalent or units consisting of more than one arm of the service. Frequently, however, a general is a staff officer who does not command troops but who plans their operations in the field. General, lieutenant general, and major general are the first,

second, and third grades of general officers in many armies. The United States Army, Air Force, and Marines have a fourth general officer grade, brigadier general (brigadier in the British Army). The highest U.S. Army rank, five-star general of the army, was created in 1944 and was conferred upon Henry Harley "Hap" Arnold, Dwight D. Eisenhower, Douglas MacArthur, and George C. Marshall in that year and upon Omar N. Bradley in 1950. The four-star rank of general of the army of the United States was established for Ulysses S. Grant in 1866 and was bestowed later upon William T. Sherman and Philip Sheridan; the unique four-star rank of general of the armies of the United States, created in 1799 for George Washington but never held by him, was conferred upon John J. Pershing in 1919.

**General Agreement on Tariffs and Trade (GATT)**, set of multilateral trade agreements aimed at the abolition of quotas and the reduction of tariff duties among the contracting nations. When GATT was concluded by 23 countries at Geneva, in 1947 (to take effect on Jan. 1, 1948), it was considered an interim arrangement pending the formation of a United Nations agency to supersede it. When such an agency failed to emerge, GATT was amplified and further enlarged at several succeeding negotiations. It subsequently proved to be the most effective instrument of world trade liberalization, playing a major role in the massive expansion of world trade in the second half of the 20th century. By the time GATT was replaced by the World Trade Organization (WTO) in 1995, 125 nations were signatories to its agreements, which had become a code of conduct governing 90 percent of world trade.

GATT's most important principle was that of trade without discrimination, in which each member nation opened its markets equally to every other. As embodied in unconditional most-favoured nation clauses, this meant that once a country and its largest trading partners had agreed to reduce a tariff, that tariff cut was automatically extended to every other GATT member. GATT included a long schedule of specific tariff concessions for each contracting nation, representing tariff rates that each country had agreed to extend to others. Another fundamental principle was that of protection through tariffs rather than through import quotas or other quantitative trade restrictions; GATT systematically sought to eliminate the latter. Other general rules included uniform customs regulations and the obligation of each contracting nation to negotiate for tariff cuts upon the request of another. An escape clause allowed contracting countries to alter agreements if their domestic producers suffered excessive losses as a result of trade concessions.

GATT's normal business involved negotiations on specific trade problems affecting particular commodities or trading nations, but major multilateral trade conferences were held periodically to work out tariff reductions and other issues. Seven such "rounds" were held from 1947 to 1993, starting with those held at Geneva in 1947 (concurrent with the signing of the general agreement); at Annecy, France, in 1949; at Torquay, Eng., in 1951; and at Geneva in 1956 and again in 1960-62. The most important rounds were the so-called Kennedy Round (1964-67), the Tokyo Round (1973-79), and the Uruguay Round (1986-94), all held at Geneva. These agreements succeeded in reducing average tariffs on the world's industrial goods from 40 percent of their market value in 1947 to less than 5 percent in 1993.

The Uruguay Round negotiated the most ambitious set of trade-liberalization agreements in GATT's history. The worldwide

trade treaty adopted at the round's end slashed tariffs on industrial goods by an average of 40 percent, reduced agricultural subsidies, and included groundbreaking new agreements on trade in services. The treaty also created a new and stronger global organization, the WTO, to monitor and regulate international trade. GATT went out of existence with the formal conclusion of the Uruguay Round on April 15, 1994. Its principles and the many trade agreements reached under its auspices were adopted by the WTO.

**General Assembly**, one of the six principal organs of the United Nations, and the only body in which every member of the organization is represented. The General Assembly convenes annually or in special sessions and exercises deliberative, supervisory, financial, and elective functions relating to any matter within the scope of the UN charter. These functions include the admission of new nations to membership, control of the budget, choice of members of the Economic and Social Council and of the elective members of the Security Council and the Trusteeship Council, and participation in the election of judges of the International Court of Justice and in the appointment of the secretary-general. The Assembly elects a new president annually, with the office rotating each year among five groups of states: African, Asian, eastern European, Latin American, and western European and other states. At the beginning of each regular session, the Assembly also holds a general debate, in which all members participate and may raise any issue of international concern. Most work, however, is delegated to seven main committees on: disarmament and related international security matters; political issues; economic and financial matters; social, humanitarian, and cultural matters; issues of decolonization; administrative and budgetary matters; and legal matters. *See also* United Nations.

**General Confederation of Labour (France)**: *see* Confédération Générale du Travail.

**General Confederation of Labour-Work Force (France)**: *see* Confédération Générale du Travail-Force Ouvrière.

**General Council of Congregational Christian Churches**, Protestant church in the United States, organized in 1931 by a merger of the National Council of the Congregational Churches and the General Convention of the Christian Church. It was merged with the Evangelical and Reformed Church into the United Church of Christ in 1957.

The Congregational churches developed from the churches established by the settlers at Plymouth, Mass. (1620), and at Massachusetts Bay (1630). Local congregations were independent, and a national governing body was not established for many years, though the churches cooperated in many areas. In 1852 representatives from all the Congregational churches met in Albany, N.Y., to discuss a plan of union. In 1871 a national Congregational organization, the National Council, was established at Oberlin, Ohio, and national councils were held regularly from that date. At the time of the merger with the Christian Church in 1931, the Congregational churches had about 943,500 members.

The Christian Church developed from three independent groups that had withdrawn from the Methodist, Baptist, and Presbyterian denominations in the late 1700s and early 1800s. The three groups began cooperating a few years later in a General Council. The Bible was the only rule of faith, church government was congregational, and complete freedom of belief was allowed.

**General Dynamics Corp.**, major American defense contractor. The company's headquarters are in St. Louis, Mo., U.S.

The original company, the Electric Boat Company, was founded in 1899 and built the *Holland*, the first submarine purchased by the U.S. Navy, in 1900. Electric Boat continued to build submarines and surface ships, and in 1954 it launched the *Nautilus*, the world's first nuclear-powered submarine. The firm was incorporated under its present name in 1952. The company began to diversify into other defense industries after World War II and became a leading manufacturer of military aircraft in the 1950s. While continuing to build submarines, it also developed and manufactured military, commercial, and private aircraft; space vehicles; armored vehicles; and advanced electronics and communications equipment. General Dynamics produced the F-16 fighter jet, the F-111 fighter bomber, and the M-1 tank. The company also became a major builder of liquid natural-gas tankers and was the prime contractor for the U.S. Navy's Trident nuclear submarine program.

Following the end of the Cold War, General Dynamics sold off its fighter aircraft, private aircraft, and missile-systems businesses in 1992. Its Electric Boat division continued to build submarines of all types, while other divisions produced M-1 battle tanks, space-launch vehicles, and electronics and communications equipment. A majority of General Dynamics' annual revenues continued to be derived from government contracts with the United States.

**General Electric Co. (GE)**, major American corporation and one of the largest and most diversified corporations in the world. Its products include electrical and electronic equipment, plastics, aircraft engines, medical imaging equipment, and financial services. Headquarters are in Fairfield, Conn., U.S.

The company was incorporated in 1892, acquiring all the assets of the Edison General Electric Company and two other electrical companies. Edison General had been founded as the Edison Electric Light Company in 1878 by Thomas Alva Edison to market his incandescent lamp and other later products. Edison remained associated with General Electric through his patents and consulting duties.

General Electric established an industrial research laboratory in 1900, and many of its later products were developed by in-house scientists. It produces one of the largest lines of electrical consumer goods in the world, and, through its General Electric and Hotpoint appliance brands, it is a top seller of various types of home appliances.

While its consumer products are most visible to the general public, they account for a minority of the company's annual sales. General Electric is also engaged in manufacturing jet engines, industrial products and components, and power systems for electric utilities. GE Financial Services, Inc., is involved in real estate and business financing, reinsurance, and investment banking. A substantial portion of the company's sales are to the U.S. Department of Defense.

In 1986 GE purchased the RCA Corporation (which it had helped to found in 1919), including the RCA-owned television network, the National Broadcasting Company, Inc. In 1987, however, GE sold RCA's consumer electronics division to Thomson SA, a state-owned French firm, and purchased Thomson's medical technology division. In 1989 GE agreed to combine its European business interests in appliances, medical systems, electrical distribution, and power systems with the unrelated British corporation General Electric Company.

**General Foods Corporation**, former American manufacturer of packaged grocery and meat products.

The company was incorporated in 1922, having developed from the earlier Postum Cereal Co. Ltd., founded by C.W. Post (1854–1914) in 1895 in Battle Creek, Mich. After a number of experiments, Post marketed his first product—the cereal beverage called Postum—in 1895. Other profitable products followed, notably Grape Nuts (1897), Post Toasties (1904), and, after Post's death, Post 40% Bran Flakes (1922). From 1925 to 1929 the Postum company began absorbing other firms: Jell-O Company in 1925; Igleheart Brothers (Swans Down flour) and Minute Tapioca Co. in 1926; Franklin Baker (coconut), Walter Baker (chocolate), and Log Cabin (syrup) in 1927; La France Company (bluing), Maxwell House (coffee), and Calumet (baking powder) in 1928; and Certo (pectin) and Birdseye (frozen foods) in 1929. Several other products eventually came into the organization, such as Sanka coffee (1932), Gaines dog food (1943), Bird's Custard Powder (1947), Kool-Aid (1953), W. Atlee Burpee garden products (1970), Oscar Mayer & Company meat products (1981), and Entenmann's Inc. bakery products (1982).

As early as 1908, Post had established foreign operations, including the Canadian Postum Company Ltd., in Windsor, Ont., and the Grape-Nuts Company Ltd., in London. By the late 20th century General Foods had manufacturing plants in most of western Europe and in such other nations as Japan, Australia, Mexico, Venezuela, and Brazil. In 1985 General Foods Corporation was bought by Philip Morris Companies Inc. (*q.v.*).

**General Grant National Memorial**, also called GRANT'S TOMB, mausoleum of U.S. President Ulysses S. Grant in New York City, standing on a bluff overlooking the Hudson River. It was designed by John H. Duncan. The monument, 150 feet (46 m) high in gray granite, was erected at a cost of \$600,000 raised by public contributions. It was dedicated April 27, 1897, and made a national memorial in 1959. The memorial is a combination of several classical styles, its lower section supporting a rotunda surrounded by Ionic columns and surmounted by a conical dome. Massive bronze doors lead to a white marble interior, in the centre of which is an open crypt containing the sarcophagi of the general and his wife, Julia Dent Grant.

**General Italian Confederation of Labour (Italy)**: *see* Confederazione Generale Italiana del Lavoro.

**General Mills, Inc.**, leading American producer of packaged consumer foods, especially flour, breakfast cereals, snacks, prepared mixes, and similar products. Headquarters are in Minneapolis, Minn.

General Mills was incorporated in 1928 to acquire Washburn Crosby Company, a flour-milling company formed in 1866, and four other milling companies. Specializing in cereals and flour products, the company grew as a food processor through the years of the Great Depression. Products include Wheaties and Cheerios (originally introduced as Cheerioats in 1941; renamed Cheerios four years later) breakfast cereals, Gold Medal flour, and Bisquick baking mix. During its early years, the company also created a fictional personage, Betty Crocker, that became one of America's most widely known food advisers.

From the early 1960s to the mid-1980s, the company diversified into nonfood businesses such as toys and apparel, but it returned its focus to foods, purchasing the Chex cereal and snack brands in 1997 from the former Ralston Purina company. General Mills then doubled in size when it acquired its former rival, Pillsbury, in 2001. The acquisition provided brands, symbols, and products such as the Pillsbury Doughboy and associated foods, Green Giant vegetables, and the Pillsbury Bake-Off Contest.

**General Motors Corporation (GM)**, American corporation that became the world's largest vehicle manufacturer in 1931 and maintained that status into the 21st century. It operates manufacturing and assembly plants and distribution centres throughout the United States and Canada and many other countries. Its major products include automobiles and trucks, automotive components, engines, and defense and aerospace matériel. Its subsidiary General Motors Acceptance Corporation (GMAC), founded in 1919 to finance and insure the installment sales of GM products, entered the mortgage business in 1985 and expanded into commercial finance in 1999. Headquarters are in Detroit, Mich.

Under the leadership of William C. Durant, the General Motors Company was founded in 1908 to consolidate several motorcar companies producing Buick, Oldsmobile, Cadillac, Oakland (later Pontiac), Ewing, Marquette, and other automobiles, as well as Reliance and Rapid trucks. GM introduced the electric self-starter commercially in its 1912 Cadillac, making the hand crank obsolete. GM was reincorporated and named General Motors Corporation in 1916. The Chevrolet auto company and Delco Products joined GM in 1918, and the Fisher Body Company and Frigidaire joined in 1919 (the latter was sold in 1979).

Durant was forced out of the company in 1920 and was succeeded by Alfred P. Sloan, Jr., who served as president (1923–37) and then as chairman of the board of directors (1937–56). Sloan reorganized GM from a sprawling, uncoordinated collection of business units into a single enterprise consisting of five main automotive divisions—Cadillac, Buick, Pontiac, Oldsmobile (discontinued in 2004), and Chevrolet. The various divisions remained autonomous within a framework of overall policy; it was this decentralized concept of management that became a model for large-scale industrial enterprises in the United States. Sloan also greatly strengthened GM's sales organization, pioneered annual style changes in car models, and developed innovations in consumer financing.

By 1929 General Motors had passed the Ford Motor Company to become the leading American passenger-car manufacturer. The company added overseas operations, including Vauxhall of England in 1925, Adam Opel of Germany in 1929, and Holden of Australia in 1931. The Yellow Truck & Coach Manufacturing Co. (now GMC Truck & Coach Division), organized in 1925, was among the new American divisions and subsidiaries to be established. By 1941 GM was making 44 percent of all the cars in the United States and had become one of the largest industrial corporations in the world.

In the 1950s and '60s GM continued to hold 40–45 percent of total U.S. automotive sales. It bought Electronic Data Systems Corporation, a large data-processing company, in 1984 and acquired the Hughes Aircraft Company, a maker of weapons systems and communications satellites, in 1986.

In 1984 GM, facing competition from Japanese automakers in the 1970s and '80s, began a new division, Saturn, that used highly automated plants to produce subcompact cars. While GM's modernization efforts showed some success, heavy losses in the early 1990s forced the company to close many plants and reduce its workforce by tens of thousands.

Like other American automakers, however, GM made a robust recovery in the middle of the decade and returned its focus to its automotive businesses. It sold Electronic Data Systems in 1996 and the following year sold the defense units of its Hughes Electronics subsidiary. By the early 21st century, GM had equity shares in a number of car companies, including Fiat, Isuzu, Fuji Heavy Industries (Subaru), and Suzuki. In 2000 it became the sole owner of Saab Automobile AB.

**General, Municipal, and Boilermakers' Union (GMB)**, formerly GENERAL AND MUNICIPAL WORKERS' UNION (GMWU), one of the largest trade unions in the United Kingdom and one of Britain's two general unions (the other being the Transport and General Workers' Union). The General and Municipal Workers' Union was formed in 1924 by the merger of the National Union of Gas and General Workers, the National Amalgamated Union of Labour, and the Municipal Employees' Association. The union's membership originally comprised unskilled workers spread across a wide range of industries, particularly public utilities, local government, chemicals and rubber, engineering and shipbuilding, and food and drink manufacturing. Later in the 20th century, the GMWU drew increasing numbers of skilled and white-collar workers. Thus, in 1982 it merged with the craft-based Amalgamated Society of Boilermakers to form the General, Municipal, and Boilermakers' Union, and in 1989 the latter merged with the white-collar Association of Professional, Executive, Clerical, and Computer Staff. The GMB had about 700,000 members in the early 21st century.

**General San Martín**, formerly SAN MARTÍN, *cabecera* (county seat) and *partido* (county) of Gran ("Greater") Buenos Aires, Argentina. It lies immediately northwest of the city of Buenos Aires, in Buenos Aires *provincia*. The county seat and county began as an early rural settlement centred on the 18th-century Chapel of Santos Lugares. In 1856 the settlement was formally declared a town, and eight years later the county of San Martín (named for the Argentine liberator) was created. Besides the county seat of General San Martín, the major localities in the county are San Andrés, José León Suárez, and Villa Ballester. In 1911 General San Martín town was given official city status, and since then it has grown into a major industrial centre, processing and manufacturing linseed oil, textiles, dairy products, frozen meat, cigarettes, liquor, and a variety of other products.

With the growth of the national capital, General San Martín has been absorbed into Gran Buenos Aires. Area *partido*, 22 square miles (56 square km). Pop. (2001 prelim.) *partido*, 405,122.

**General Santos**, formerly (1954) BUAYAN, city, southern Mindanao, Philippines. The city is named for General Paulino Santos, who directed the pioneer settlement (mostly by Christian Filipino migrants) and development of the Koronadal Valley that began in the mid-1930s. General Santos city is located at the head of Sarangani Bay of the Celebes Sea along the southern shore of Mindanao. The city is a principal shipping point and is also administrative headquarters for the Koronadal settlement projects. A number of small-scale manufacturing companies are located there, along with banana, pineapple, and cassava plantations. Its national port, the largest in southern Mindanao, is the port of entry for overseas shipping in the region. General Santos also has a national airport. Inc. city, 1968. Pop. (2000) mun., 411,822.

**General Sarmiento**, *partido* (county) of Gran ("Greater") Buenos Aires, Argentina. It lies northwest of the city of Buenos Aires, in Buenos Aires *provincia*. The early settlement of the county centred on the agricultural plantation San José del Pilar, established by Adolfo Sordeaux in 1862. This plantation settlement led Sordeaux to establish the towns of San Miguel and Bella Vista in 1872. In 1889 General Sarmiento county (named for Domingo Faustino Sarmiento, Argentine president, 1868–74) was created by expropriating

lands from Pilar and Moreno counties. Besides the *cabeceira* (county seat) of San Miguel, the major localities in the county are Bella Vista, Jose C. Paz, and Villa de Mayo. General Sarmiento now lies almost totally within the Gran Buenos Aires urban area. Three major railways running northwest from Buenos Aires serve the county. Area 76 square miles (196 square km). Pop. (1991 prelim.) 646,891.

**General Security, Committee of**, French COMITÉ DE SÛRETÉ GÉNÉRALE, organ of the French Revolutionary government. It directed the political police and Revolutionary justice. Founded by the National Convention in 1792, the committee administered the Reign of Terror of 1793-94, along with the Committee of Public Safety. *See also* Revolutionary Tribunal.

**general semantics**, a philosophy of language-meaning that was developed by Alfred Korzybski (1879-1950), a Polish-American scholar, and furthered by S.I. Hayakawa, Wendell Johnson, and others; it is the study of language as a representation of reality. Korzybski's theory was intended to improve the habits of response to environment. Drawing upon such varied disciplines as relativity theory, quantum mechanics, and mathematical logic, Korzybski and his followers sought a scientific, non-Aristotelian basis for clear understanding of the differences between symbol (word) and reality (referent) and the ways in which words themselves can influence (or manipulate) and limit human ability to think.

A major emphasis of general semantics has been in practical training, in methods for establishing better habits of evaluation, e.g., by indexing words, as "man<sub>1</sub>," "man<sub>37</sub>," and by dating, as "Roosevelt<sub>1930</sub>," "Roosevelt<sub>1940</sub>," to indicate exactly which man or which stage of time one is referring to.

Korzybski's major work on general semantics is *Science and Sanity* (1933; 3rd ed., 1948). The International Society for General Semantics (founded 1942 as the Society for General Semantics) publishes a quarterly, *Review of General Semantics*, and *ETC.*, a periodical.

**general staff**, in the military, a group of officers that assists the commander of a division or larger unit by formulating and disseminating his policies, transmitting his orders, and overseeing their execution. Normally a general staff is organized along functional lines, with separate sections for administration, intelligence, operations, training, logistics, and other categories. In many countries a similar but more elaborately organized staff assists the supreme military authority. While a general staff contains specialists as well as more broadly trained officers, it is distinguished in character and functions from special staffs (in the U.S. Army) consisting of technical specialists in the various services: medical, police, communications, supply, and others.

Although the name general staff was sometimes applied to high military staffs in the 18th century, the institution did not appear in its modern form until the early 19th century, in the Prussian army, and in other European countries after 1870. The U.S. Army created a general staff in 1903, the British army in 1906. In the British and U.S. armies, however, the general staff differed from that of the Prussian army in that the officers, although especially qualified, were not trained as an elite corps; they were individually selected from the officer corps as a whole just as for other assignments. The air force counterpart of army general staff is usually called the air staff.

**general store**, retail store in a small town or rural community that carries a wide variety of goods, including groceries. In the United States the general store was the successor of

the early trading post, which served the pioneers and early settlers. Located at a crossroads or in a village, it served the surrounding community and farmers from the neighbouring countryside and carried a wide variety of goods, including food, clothing, housewares, and farm equipment. Because money was scarce in many rural areas, some of the trade was accomplished through barter. The general store served as a meeting place for members of the community, of which the storekeeper was an important member, not only because he supplied material goods but because he was also the source of news and gossip. Because produce from the land and forest tended to yield a seasonal return, the storekeeper might also extend long-term credit of from six months to a year to his customers.

The American general store flourished throughout the 19th century but declined rapidly in the 20th century, particularly after the 1920s. It was mostly succeeded by specialized stores, each handling a particular type of goods.

**general strike**, stoppage of work by a substantial proportion of workers in each of a number of industries in an organized endeavour to achieve economic or political objectives. A strike covering only one industry cannot properly be called a general strike.

The idea of a general strike, as a deliberate part of the tactics of collective bargaining, apparently began in Great Britain, where the term had entered the language by the 1830s. The theory of the general strike as a method of social revolution was developed later in the century in France by syndicalist thinkers, who believed that workers could achieve a social revolution by using a general strike to directly overthrow the capitalist owners of industry.

General strikes first became possible with the growth of large trade unions late in the 19th century. Two large general strikes occurred in Belgium in 1893 and 1902 in support of universal manhood suffrage. A large-scale strike took place in Sweden in 1902 over similar issues and was followed by one in Italy in 1904 protesting the use of soldiers as strike-breakers. The general strike that gripped Russia during the Revolution of 1905 forced the tsar to issue the October Manifesto, in which he promised to create a constitution and a national legislature. In 1909 Sweden had another general strike, this time in response to the wage-freeze and lockout policies adopted by employers because of falling profits. Nearly half of the country's total workforce struck, and the stoppage lasted a month before the strike was settled. The Swedish general strike encouraged the idea in other countries that major economic reforms could be achieved without resorting to violence.

A general strike in Berlin thwarted a right-wing takeover of the German government in 1920. In 1926 Britain faced one of the largest of all general strikes, which was undertaken by the Trades Union Congress in support of the nation's coal miners, who were in a bitter dispute with the mine owners. About 3,000,000 of Britain's 5,000,000 trade-union members were involved in the strike, which was intended to force the government to intervene in the coal dispute. The strike lasted only nine days and ended on May 12, however, after the TUC realized that it was unable to prevent the government from keeping essential services running.

General strikes have been infrequent in Europe since World War II. Notable exceptions were the outbreak of a general strike in France (May 1967), touched off by student demands for educational reform, and nationwide strikes for social security and educational reform in Italy (November 1968) involving more than 12,000,000 workers.

In the United States, labour has accepted in principle the inviolability of the collective con-

tract and consequently has in principle always opposed the general strike. A general strike would lead to universal breaches of existing agreements and would expose weaker unions to reprisals from employers.

In Asian and African countries, trade unions allied with independence movements often resorted to general strikes as a means of political protest during colonial rule. The smallness of industry in these countries has limited all trade-union action. Wherever organized trade unions exist, however, they have continued to use the general strike as an instrument for achieving economic as well as political ends.

**General Stud Book**, in horse breeding, prototype of the breeding record of purebred horses, or studbook (*q.v.*).

**General Telephone and Electronics Corporation**: *see* GTE Corporation.

**General Union of Jewish Workers in Lithuania, Poland, and Russia**: *see* Bund.

**general will**, theory of Jean-Jacques Rousseau, 18th-century French political philosopher, that in a democratic society the state represents the general will of the citizens, and that in obeying its laws each citizen is pursuing his own real interest. Rousseau distinguished the "general will" from particular wills. The general will is a moral will, a will that aims at the common good.

Rousseau assumed that all people are capable of taking the moral standpoint of aiming at the common good, and that if they did so they would reach a unanimous decision. Thus, in an ideal state, laws express the general will. An individual who disagrees with a law must be failing to look at things from the moral standpoint. The general will expressed by the law is what that individual, no less than others, would share if he took the moral, the truly human, view.

**généralité**, the basic administrative unit of 17th- and 18th-century France. It was first established in the late 14th century to organize the collection of royal revenues. In the 15th century, four *généralités* covered most of France. An edict of 1542 established their number at 16, each under a *receveur* ("receiver") *général* (from which the unit took its name).

In the 17th century the already existing *généralité* became the sphere of authority of the intendant, a direct agent of the king with wide police, justice, and finance powers. In the language of the time, *généralité* came to be synonymous with intendency. In 1789 there were about 33 *généralités*; their boundaries were often arbitrarily chosen without any geographic or historical basis. The district seats (*chefs-lieux*), from which the *généralités* took their names, were themselves often inconveniently located in a corner of the territory.

**generalization**, in psychology, the tendency to respond in the same way to different but similar stimuli. For example, a dog conditioned to salivate to a tone of a particular pitch and loudness will also salivate with considerable regularity in response to tones of higher and lower pitch. The generalized response is predictable and orderly: it will measure less than that elicited by the original tone and will diminish as the new tone departs increasingly from the original. Similar behaviour is observed in humans, as children learning to talk may call anything that can be sat upon "chair" or any man "daddy." Adults conditioned by mild electric shock to fear a certain word will respond with symptoms of anxiety to any synonym of that word; in this instance, physical similarity, the usual basis of generalization, is less important than prior learning. Responses may also be generalized, allowing an individual to take an alternative course of action if the usual response is for some reason precluded. Learning may be considered a

balance of generalization and discrimination (the ability to respond to differences among stimuli). An imbalance can lead to negative results. For example, a child who is scared by a man with a beard may fail to discriminate between bearded men and generalize that all men with beards are to be feared.

**Generation of '98** (Spanish literature): *see* '98, Generation of.

**generative grammar**, a precisely formulated set of rules whose output is all (and only) the sentences of a language—*i.e.*, of the language that it generates. There are many different kinds of generative grammar, including transformational grammar as developed by Noam Chomsky from the mid-1950s. Linguists disagree as to which, if any, of these different kinds of generative grammar will serve as the best model for the description of natural languages.

Generative grammars do not merely distinguish the grammatical sentence of a language from ungrammatical sequences of words of the same language; they also provide a structural description, or syntactic analysis, for each of the grammatical sentences. The structural descriptions provided by a generative grammar are comparable with, but more precisely formulated than, the analyses that result from the traditional practice of parsing sentences in terms of the parts of speech.

**generator**: *see* electric generator.

**género chico** (Spanish: "little genre"), Spanish literary genre of light dramatic or operatic one-act playlets, as contrasted with the *género grande* of serious drama or opera. Developed primarily in the theatres of Madrid during the later 19th century, *género chico* works usually dealt with Madrid's lower classes, whose way of life was regarded with mingled sentimentality and satiric humour. Carlos Arniches, Ricardo de la Vega, and Tomás Luceño were the chief writers in the genre.

**Genesee River**, river that flows mainly in New York state, U.S. The Genesee flows generally north from its headwaters in Pennsylvania, crosses the New York State Barge Canal, and bisects Rochester to enter Lake Ontario after a course of 158 miles (254 km). At Portageville, midway along its course, the river flows into a 25-mile-long postglacial, winding rocky gorge with sides rising at times 800 feet (245 m) above its banks. Called the "Grand Canyon of the East," this gorge, cut into sedimentary rocks of the Appalachian Upland, is the focal point of Letchworth State Park, which is noted for its scenic beauty and is the site of a well-known Indian and Pioneer Museum. At Portage Falls, within the park, the Genesee cascades over three waterfalls. There is a flood-control dam at Mount Morris, where the river leaves the gorge to enter a wide, preglacial moraine-filled plain. At Rochester it enters another (7-mile-long) gorge containing three waterfalls, which supply industrial power. Genesee is an Iroquoian Indian term meaning "beautiful valley"; the Senecas called it Casconchiagon ("River of Many Falls").

**Genesis**, Hebrew BERESHIT ("In the Beginning"), the first book of the Old Testament. Its name derives from the opening words: "In the beginning . . ." Genesis narrates the primeval history of the world (chapters 1–11) and the patriarchal history of the Israelite people (chapters 12–50). The primeval history includes the familiar stories of the Creation, the Garden of Eden, Cain and Abel, Noah and the Flood, and the Tower of Babel. The patriarchal history begins with the divine promise to Abraham that "I will make of you a great nation" (12:2) and tells the stories of Abraham (chapters 12–25) and his descendants: Isaac and his twin sons Jacob and Esau (chapters 26–36) and Jacob's family, the principal figure being Joseph (chapters 37–50), whose story

tells how the Israelites came to be in Egypt. Their deliverance is narrated in the following book of Exodus. Genesis must thus be seen as a part of a larger unit of material traditionally understood to comprise the first five books of the Bible, called the Torah, or Pentateuch.

Scholars have identified three literary traditions in Genesis, as in Deuteronomy, usually identified as the Yahwist, Elohist, and Priestly strains. The Yahwist strain, so called because it used the name Yahweh (Jehovah) for God, is a Judean rendition of the sacred story, perhaps written as early as 950 bc. The Elohist strain, which designates God as Elohim, is traceable to the northern kingdom of Israel and was written 900–700 bc. The Priestly strain, so called because of its cultic interests and regulations for priests, is usually dated in the 5th century bc and is regarded as the law upon which Ezra and Nehemiah based their reform. Because each of these strains preserves materials much older than the time of their incorporation into a written work, Genesis contains extremely old oral and written traditions.

**Genesis, Little**: *see* Jubilees, Book of.

**Genesis Apocryphon**, pseudepigraphal work (not accepted in any canon of scripture), one of the most important works of the Essene community of Jews, part of whose library was discovered in 1947 in caves at Qumrān, near the Dead Sea, in Palestine. The scroll, the last of seven scrolls discovered in Cave I, is also the least well preserved. Examination of the entire scroll showed it to be a collection of apocryphal embellishments on leading figures in Genesis and not, as was first suspected, the long lost "Apocalypse of Lamech." The contents of the scroll comprise four major sections: the story of Lamech (columns 1–5), the story of Noah (columns 6–15), the table of the Peoples (columns 16–17), and the story of Abraham (columns 18–22).

The work is a good example of Essene biblical exegesis and shows striking similarities to the pseudepigraphal *Book of Jubilees*, which also presents a highly imaginative version of Genesis. Though their calculations differ, the two books show a common interest in the calendar. Because the scroll also contains material related to that found in *First Book of Enoch*, the *Genesis Apocryphon* was possibly the source for both *Jubilees* and *1 Enoch*.

Written in Palestine in Aramaic, the scroll is the earliest example of a pseudepigraphal work in that language and is important for the study of its linguistic development. It dates from either the 1st century bc or ad. The date of the original text, however, is difficult to determine, since the scroll may be an Aramaic translation of a Hebrew original or an altered edition of an Aramaic original.

**Genesius, Joseph** (fl. 10th century), Byzantine scholar whose history of Constantinople is one of the few known sources on the relatively obscure 9th-century period of Byzantine history.

The details of Genesius' life are unknown. He apparently composed his history between 945 and 959 at the order of Emperor Constantine VII, using his high social position to gain eyewitness reports of events from members of the royal court. Also referring to a variety of manuscripts, including chronicles and the biographical accounts of patriarchs, the *History of Constantinople* covers the Byzantine Empire from the reign of Leo the Armenian (813) to the death of Basil I in 886.

**Genêt** (American writer): *see* Flanner, Janet.

**genet**, any of about five species of lithe, catlike carnivores of the genus *Genetta*, family Viverridae. Genets are elongate, short-legged animals with long, tapering tails; pointed noses; large, rounded ears; and retractile claws. Coloration varies among species but usually is

pale yellowish or grayish, marked with dark spots and stripes; the tail is banded black and white. Adult genets weigh 1–2 kg (2.2–4.4 pounds) and are about 40–60 cm (16–24 inches) long, excluding the 40–55-centimetre tail.

Genet (*Genetta*)

Warren Garst—Van Cleve Photography

Except for the small-spotted genet (*G. genetta*), which also occurs in western Asia and southern Europe, they are found only in Africa. Genets live alone or in pairs and are active mainly at night. They frequent forests, grasslands, and brush and are as agile in the trees as on the ground. They prey on small mammals and birds. Litters contain two or three young.

**Genet, Edmond-Charles**, Genet also spelled GENEST (b. Jan. 8, 1763, Versailles, Fr.—d. July 14, 1834, Schodack, N.Y., U.S.), French emissary to the United States during the French Revolution who severely strained Franco-American relations by conspiring to involve the United States in France's war against Great Britain.

In 1781 Edmond succeeded his father, Edmé-Jacques Genet, as head of the translation department at the French Ministry of Foreign Affairs. Soon after the outbreak of the Revolution in 1789 he was made chargé d'affaires to the French legation in Russia; but his enthusiasm for the Revolution antagonized the empress Catherine II the Great, who expelled him from Russia in July 1792. Genet then identified himself with the moderate Girondin faction in the French Revolutionary government; and in April 1793 the Girondins secured his appointment as chargé d'affaires to the United States. He was instructed to seek repayment of part of the American debt to France or—at the very least—to obtain credit for purchasing the supplies needed for the war with Great Britain.

Nevertheless, Genet soon exceeded his diplomatic authority. Hailed as "Citizen Genet" by Americans who favoured the French cause, he conspired with those who opposed President George Washington's policy of neutrality. His efforts to bring the United States into the war and his highhanded arming of privateers in American ports to operate against the British brought relations between the United States and France to the brink of war and risked the loss of France's sole source of credit abroad. In August 1793 Washington, who was firmly committed to a policy of neutrality in the European conflict, requested that Genet be recalled. Realizing that he faced arrest if he returned to France, Genet chose to remain in the United States; he married the daughter of George Clinton, governor of New York, became a U.S. citizen, and settled down to farming.

**Genet, Jean** (b. Dec. 19, 1910, Paris, France—d. April 15, 1986, Paris), French

criminal and social outcast turned writer who, as a novelist, transformed erotic and often obscene subject matter into a poetic vision of the universe and, as a dramatist, became a

Jean Genet  
© Jerry Bauer

leading figure in the avant-garde theatre, especially the Theatre of the Absurd.

Genet, an illegitimate child abandoned by his mother, Gabrielle Genet, was raised by a family of peasants. Caught stealing at the age of 10, he spent part of his adolescence at a notorious reform school, Mettray, where he experienced much that was later described in the novel *Miracle de la rose* (1945–46; *Miracle of the Rose*). His autobiographical *Journal du voleur* (1949; *The Thief's Journal*) gives a complete and uninhibited account of his life as a tramp, pickpocket, and male prostitute in Barcelona, Antwerp, and various other cities (c. 1930–39). It also reveals him as an aesthete, an existentialist, and a pioneer of the Absurd.

He began to write in 1942 while imprisoned for theft at Fresnes and produced an outstanding novel, *Notre-Dame des Fleurs* (1943; *Our Lady of the Flowers*), vividly portraying the prewar Montmartre underworld of thugs, pimps, and perverts. His talent was brought to the attention of Jean Cocteau and later Jean-Paul Sartre and Simone de Beauvoir. Because Genet in 1948 was convicted of theft for the 10th time and would have faced automatic life imprisonment if convicted again, a delegation of well-known writers appealed on his behalf to the president of the French republic, and he was “pardoned in advance.”

After writing two other novels, *Pompes funèbres* (1947; *Funeral Rites*) and *Querelle de Brest* (1947; *Querelle of Brest*, filmed 1982), Genet began to experiment with drama. His early attempts, by their compact, neoclassical, one-act structure, reveal the strong influence of Sartre. *Haute Surveillance* (1949; *Death-watch*) continues his prison-world themes. *Les Bonnes* (1947; *The Maids*), however, begins to explore the complex problems of identity that were soon to preoccupy other avant-garde dramatists such as Samuel Beckett and Eugène Ionesco. With this play Genet was established as an outstanding figure in the Theatre of the Absurd.

His subsequent plays, *Le Balcon* (1956; *The Balcony*), *Les Nègres* (1958; *The Blacks*), and *Les Paravents* (1961; *The Screens*), are large-scale, stylized dramas in the Expressionist manner, designed to shock and implicate an audience by revealing its hypocrisy and complicity. This “Theatre of Hatred” attempts to wrest the maximum dramatic power from a social or political situation without necessarily endorsing the political platitudes of either the right or the left.

Genet, a rebel and an anarchist of the most extreme sort, rejected almost all forms of social discipline or political commitment. The violent and often degraded eroticism of his experience led him to a concept of mystic

humiliation. Jean-Paul Sartre's study, *Saint Genet, comédien et martyr* (1952; *Saint Genet, Actor and Martyr*), compares Genet's evident pursuit of mortification and self-abasement to that of a saint.

**genetic code**, the sequence of nucleotides in deoxyribonucleic acid (DNA) and ribonucleic acid (RNA) that determines the amino acid sequence of proteins. Though the linear sequence of nucleotides in DNA contains the information for protein sequences, proteins are not made directly from DNA. Instead, a messenger RNA (mRNA) molecule is synthesized from the DNA and directs the formation of the protein. RNA is composed of four nucleotides: adenine (A), guanine (G), cytosine (C), and uracil (U). Three adjacent nucleotides constitute a unit known as the codon, which codes for an amino acid. For example, the sequence AUG is a codon that specifies the amino acid methionine. There are 64 possible codons, three of which do not code for amino acids but indicate the end of a protein. The remaining 61 codons specify the 20 amino acids that make up proteins. The AUG codon, in addition to coding for methionine, is found at the beginning of every mRNA and indicates the start of a protein. Because most of the 20 amino acids are coded for by more than one codon, the code is called degenerate.

The genetic code, once thought to be identical in all forms of life, has been found to diverge slightly in certain organisms and in the mitochondria of some eukaryotes. Nevertheless, these differences are rare, and the genetic code is identical in almost all species, with the same codons specifying the same amino acids.

**genetic drift**, also called **GENETIC SAMPLING ERROR**, or **SEWALL WRIGHT EFFECT**, a change in the gene pool of a small population that takes place strictly by chance. Genetic drift can result in genetic traits being lost from a population or becoming widespread in a population without respect to the survival or reproductive value of the alleles involved. A random statistical effect, genetic drift can occur only in small, isolated populations in which the gene pool is small enough that chance events can change its makeup substantially. In larger populations, any specific allele is carried by so many individuals that it is almost certain to be transmitted by some of them unless it is biologically unfavourable. See also founder principle.

**genetic engineering**, the artificial manipulation, modification, and recombination of DNA or other nucleic acid molecules in order to modify an organism or population of organisms.

A brief treatment of genetic engineering follows. For full treatment, see **MACROPAEDIA: Genetics and Heredity, Principles of**.

The term genetic engineering initially meant any of a wide range of techniques for the modification or manipulation of organisms through the processes of heredity and reproduction. As such, the term embraced both artificial selection and all the interventions of biomedical techniques, among them artificial insemination, *in vitro* fertilization (e.g., “test-tube” babies), sperm banks, cloning, and gene manipulation. But the term now denotes the narrower field of recombinant DNA technology, or gene cloning, in which DNA molecules from two or more sources are combined either within cells or *in vitro* and are then inserted into host organisms in which they are able to propagate. Gene cloning is used to produce new genetic combinations that are of value to science, medicine, agriculture, or industry.

DNA is the carrier of genetic information; it achieves its effects by directing the synthesis of proteins. Most recombinant DNA technology involves the insertion of foreign genes into the plasmids of common laboratory strains of bacteria. Plasmids are small rings of DNA; they

are not part of the bacterium's chromosome (the main repository of the organism's genetic information). Nonetheless, they are capable of directing protein synthesis, and, like chromosomal DNA, they are reproduced and passed on to the bacterium's progeny. Thus, by incorporating foreign DNA (for example, a mammalian gene) into a bacterium, researchers can obtain an almost limitless number of copies of the inserted gene. Furthermore, if the inserted gene is operative (i.e., if it directs protein synthesis), the modified bacterium will produce the protein specified by the foreign DNA.

Genetic engineering has advanced the understanding of many theoretical and practical aspects of gene function and organization. Through recombinant DNA techniques, bacteria have been created that are capable of synthesizing human insulin, human growth hormone, alpha interferon, a hepatitis B vaccine, and other medically useful substances. Plants may be genetically adjusted to enable them to fix nitrogen, and genetic diseases can possibly be corrected by replacing “bad” genes with “normal” ones. Nevertheless, special concern has been focused on such achievements for fear that they might result in the introduction of unfavourable and possibly dangerous traits into microorganisms that were previously free of them—e.g., resistance to antibiotics, production of toxins, or a tendency to cause disease.

The “new” microorganisms created by recombinant DNA research were deemed patentable in 1980, and in 1986 the U.S. Department of Agriculture approved the sale of the first living genetically altered organism—a virus, used as a pseudorabies vaccine, from which a single gene had been cut. Since then several hundred patents have been awarded for genetically altered bacteria and plants.

**genetics**, the study of heredity in general and of genes in particular.

A brief treatment of genetics follows. For full treatment, see **MACROPAEDIA: Genetics and Heredity, Principles of**.

Although the influence of heredity has been recognized since prehistoric times, scientific understanding of inheritance is a fairly recent event. Modern genetics began with the work of Gregor Mendel, an Austrian monk whose breeding experiments with garden peas led him to formulate the basic laws of heredity. Mendel concluded that his plants inherited two factors (one from each parent) for each of the hereditary traits he studied. He further deduced that these factors do not mix in the offspring, that some factors are dominant over others, and that a parent plant randomly transmits one factor from each pair to an offspring.

Mendel published his findings in 1866, but his discoveries were not appreciated by the scientists of his day. By the turn of the century, however, the intellectual climate had changed; in 1900 a number of researchers independently rediscovered Mendel's work and grasped its significance.

The infant science of genetics flowered rapidly. By 1902 Walter Sutton of the United States had proposed that chromosomes—major components of the cell nucleus—were the site of Mendel's hereditary factors. The Hardy-Weinberg law, which established the mathematical basis for studying heredity in populations, was independently formulated by the English mathematician Godfrey H. Hardy and the German physician Wilhelm Weinberg in 1908. In 1910 the American geneticist Thomas Hunt Morgan began his studies with the fruit fly, *Drosophila melanogaster*. Morgan provided evidence not only that genes (as Mendel's factors had come to be called) occur on chromosomes but that those genes lying close together on the same chromosome form linkage groups that tend to be inherited together.

During the 1940s George W. Beadle and Edward L. Tatum of the United States demonstrated that genes exert their influence by directing the production of enzymes, proteins that facilitate chemical reactions in the cell. By 1944 Oswald T. Avery had shown that deoxyribonucleic acid (DNA) was the chromosome component that carried genetic information. The molecular structure of DNA, however, was not deduced until 1953 by James D. Watson of the United States and Francis H.C. Crick of Great Britain. By 1961 the French geneticists François Jacob and Jacques Monod had developed a model for the process by which DNA directs protein synthesis in bacterial cells. These developments led to the deciphering of the genetic code of the DNA molecule, which in turn made possible the recombinant DNA techniques that hold immense potential for genetic engineering (*q.v.*).

Modern genetics studies include population genetics (the study of genetic patterns within populations), classical genetics (how traits are transmitted and expressed), cytogenetics (the mechanics of heredity within the cell), microbial genetics (the heredity of microorganisms), and molecular genetics (the molecular study of genes and related structures). To some extent, these divisions are artificial; every field overlaps with other genetic fields, and all have implications for the other biological sciences. Genetics has been applied to the diagnosis, prevention, and treatment of hereditary diseases; to the breeding of plants and animals; and to the development of industrial processes that utilize microorganisms.

**Geneva**, French GENÈVE, German GENÈ, Italian GINEVRA, city, capital of Genève canton, southwestern Switzerland. The city, located in the Rhône River valley at the extreme southwestern corner of Lake Geneva (Lac Léman) near the French frontier, was the centre of the Calvinist Reformation. Modern Geneva is a centre of financial activity and the headquarters of many international organizations.

A brief treatment of Geneva follows. For full treatment, see MACROPAEDIA: Geneva.

Geneva grew on a hill in the centre of a natural basin between the Alps and the Jura Mountains, where the Rhône River exits Lake Geneva. The city exhibits the classic pattern of old European cities, with a concentric arrangement of neighbourhoods around the original nucleus. The climate in and around Geneva is tempered by the presence of Lake Geneva, while the Jura create a barrier that diminishes rainfall.

Geneva has functioned primarily as a centre of commerce and finance, important not only in Europe but throughout the world. Its economy emphasizes trade, banking, and insurance. Geneva is a sanctuary for international capital, holding half of all the foreign capital in Switzerland. Geneva's industry, though hampered by lack of space and raw materials, has developed diversified exports that include precision machinery and instruments, watches and jewelry, chemicals, and food.

Many international institutions have established headquarters in Geneva. The International Red Cross was founded there in 1864, and the League of Nations was installed in 1919. In 1945 Geneva became the European headquarters of the United Nations and its related organs.

The Haute-ville ("Upper City"), centred on Geneva's original hill site and marked by the Cathedral of St. Peter, is the historic heart and civic centre of Geneva. Suburbs have grown up on the site of the old fortifications, mostly to the south of the Rhône, and beyond them is an irregular belt of working-class residential areas close to the railway stations and the industrial zone.

The University of Geneva, founded by the Reformation leader John Calvin in 1559 as Schola Genevensis (later called the Academy),

draws a large number of foreign students attracted by its reputation in international studies, botany, and education. The city's modern cultural life is based on its museums, musical events, and international meetings.

Of the many roads radiating from Geneva, only a few connect the city to other Swiss towns, with most leading into France. Rail and highway facilities link the city to Swiss and French towns. Geneva's international airport is 3 miles (5 km) northwest of the city. Area city, 7 square miles (18 square km); metropolitan area, 80 square miles (208 square km). Pop. (1991 est.) city, 167,167; metropolitan area, 394,783.

**Geneva** (*canton*, Switzerland): see Genève.

**Geneva, Academy of**, French ACADÉMIE DE GENÈVE, also called INSTITUT JEAN-JACQUES ROUSSEAU, private school of education founded at Geneva, Switz., in 1912 by a Swiss psychologist, Édouard Claparède, to advance child psychology and its application to education. A pioneer of scientific-realist education, Claparède believed that, as opposed to automatic learned performance or simple reflex, thinking must be developed in children, and that education must be tailored to fit the child (*l'école sur mesure*)—"the school made to measure". The institute soon attracted students from all over the world. Claparède's work was furthered by his protégé Jean Piaget, who became director of research at the institute in 1921. Piaget's investigations resulted in a series of influential articles and books on child psychology, stressing the intellectual development of the child. In the 1930s, as vice-director and then director of the institute, Piaget helped to reorganize it as part of the University of Geneva.

**Geneva, Lake**, French LAC LÉMAN, or LAC DE GENÈVE, German GENFERSEE, largest Alpine lake in Europe (area 224 square miles [581 square km]), lying between southwestern Switzerland and Haute-Savoie département, southeastern France. About 134 square miles (347 square km) of the lake's area are Swiss, and 90 square miles (234 square km) are French. Crescent in shape, the lake is formed by the Rhône River, which enters it at the east end between Villeneuve, Switz., and Saint-Gingolph, France, and leaves it at the west end through the city of Geneva. The only important tributaries are the Dranse (south) and the Venoge (north). Lying at an elevation of 1,220 feet (372 m), the lake is 45 miles (72 km) long, with a maximum width of 8.5 miles (13.5 km) and an average width of 5 miles (8 km). The maximum depth is 1,017 feet (310 m), the mean depth 262 feet (80 m). The strait of Promenthoux, or Nernier, separates the lake into two well-marked divisions, the Grand Lac (east) and the Petit Lac, the special Genevese portion. The water, unusually blue and transparent, is subject to remarkable fluctuations of level known as seiches, in which the whole fluid mass in the lake rhythmically swings from shore to shore. The lake is not as rich in fish as the other Swiss lakes; there are known to be 20 indigenous species and 6 that were introduced in the 19th century.

Prehistoric lake dwellings have been found on the shores. The Lacus Lemanus of classical Latin writers, it was known from the 16th century as the Lac de Genève, but the name Lac Léman was revived from the end of the 18th century.

The north shore forms a fertile wine-producing hinterland rising to the Jura Mountains, whereas the south and east shores are bordered by the Savoy and Valaisian Alps. Geneva and Lausanne are the largest lakeside cities, and there are numerous resorts, including Montreux and Vevey in Switzerland and Thonon-les-Bains and Évian-les-Bains in France.

**Geneva Accords**, collection of documents relating to Indochina and issuing from the

Geneva Conference of April 26–July 21, 1954, attended by representatives of Cambodia, the People's Republic of China, France, Laos, the United Kingdom, the United States, the Soviet Union, the Viet Minh (*i.e.*, the North Vietnamese), and the State of Vietnam (*i.e.*, the South Vietnamese). The 10 documents—none of which were treaties binding the participants—consisted of 3 military agreements, 6 unilateral declarations, and a Final Declaration of the Geneva Conference (July 21, 1954).

Following intensive negotiations, beginning on May 8, 1954, the day after the fall of the French garrison at Dien Bien Phu, agreements were finally signed on July 21 between the French and Vietnamese, Laotian, and Cambodian representatives. The principal provisions were for a cease-fire line along the 17th parallel (effectively dividing Vietnam in two); 300 days for each side to withdraw its troops to its side of the line; and communist troops and guerrillas to evacuate Laos and Cambodia, where free elections would be held in 1955 and where French troops could be stationed if the Laotian or Cambodian governments should so request. It was stipulated explicitly that the partition line "should not in any way be interpreted as constituting a political or territorial boundary." Execution of the agreements was to be supervised by a commission of representatives from India, Poland, and Canada. A provision that was known as the Final Declaration stipulated that all-Vietnamese elections were to be held under the supervision of the committee before July 1956 to reunify the country. This was a matter of great importance in inducing the Viet Minh to accept the temporary regrouping of its forces in the northern half of the country, because on the eve of the conference it controlled three-quarters of Vietnam.

Most of the nine participating countries pledged themselves to guarantee the agreements, but the United States made it clear that it was not bound by them. The South Vietnamese also withheld approval, and the Final Declaration was left unsigned by all parties. The U.S. government undertook to build a separate anticommunist state in South Vietnam and in 1956 supported South Vietnam's refusal to hold nationwide elections in consultation with North Vietnam.

**Geneva Bible**, also called BREECHES BIBLE, new translation of the Bible published in Geneva (New Testament, 1557; Old Testament, 1560) by a colony of Protestant scholars in exile from England who worked under the general direction of Miles Coverdale and John Knox and under the influence of John Calvin. The English churchmen had fled London during the repressive reign of the Roman Catholic Mary I, which had halted the publication of Bibles there.

The work acquired the sobriquet "Breeches Bible" because it described Adam and Eve as having made "breeches" to cover their nakedness (Genesis 3:7), instead of "aprons" or "loincloths." The Great Bible (named for its large page size and first ordered by Henry VIII in 1538) was restored to the churches after Elizabeth I's succession halted persecution of Anglicans and Protestants, but the Geneva Bible, imported from Europe and not printed in England until 1576, quickly surpassed the Great Bible in public favour. The work's enduring popularity made the Geneva Bible an important influence on the translators of the King James Version of 1611.

**Geneva Catechism**, doctrinal confession prepared by John Calvin to instruct children in Reformed theology. Recognizing that his first catechism (1537) was too difficult for children, Calvin rewrote it. He arranged the Geneva

Catechism (1542) in questions and answers in an effort to simplify doctrinal complexities.

The Geneva Catechism is primarily concerned with man's relationship to God. It is composed of five sections: (1) faith, with an exposition of the Apostles' Creed, (2) the law (the Ten Commandments), (3) prayer, (4) the Word of God, and (5) the sacraments. Used principally in Geneva and Scotland, it was superseded by the Heidelberg and Westminster catechisms, both of which were indebted to Calvin's work.

**Geneva City Conservatory and Botanical Gardens**, FRENCH CONSERVATOIRE ET JARDIN BOTANIQUES DE LA VILLE DE GENÈVE, major botanical research centre in Geneva, Switz., specializing in such areas as floristics, biosystematics, and morphology. Founded in 1817, the 19-hectare (47-acre) municipal garden cultivates about 15,000 species of plants; it has important collections of alpine plants and orchids, an arboretum, and special plantings for pedagogic purposes. Many of the plantings are arranged to show characteristic species of different geographic regions of the world. Of the garden's greenhouses, five are designed for public display and three for service functions. Its herbarium, consisting of about five million reference specimens with a worldwide geographic representation, is one of the great collections of Europe. The garden also has an extensive library and a large scientific staff.

**Geneva Convention**, any of a series of international treaties concluded in Geneva, Switz., between 1864 and 1949, for the purpose of ameliorating the effects of war on soldiers and civilians.

The history of the conventions is closely associated with that of the Red Cross, whose founder, Henri Dunant, initiated international negotiations establishing in 1864 the Convention for the Amelioration of the Wounded in Time of War. This provided for (1) the immunity from capture and destruction of all establishments for the treatment of wounded and sick soldiers and their personnel, (2) the impartial reception and treatment of all combatants, (3) the protection of civilians rendering aid to the wounded, and (4) recognition of the Red Cross symbol as a means of identifying persons and equipment covered by the agreement.

This first convention was ratified within three years by all the European great powers, as well as by many lesser states. It was amended and extended by the second Geneva Convention in 1906. Also, by the Hague conventions of 1899 and 1907, its provisions were applied to maritime warfare. In 1929 the third Geneva Convention, the Convention Relating to the Treatment of Prisoners of War, made provision for the protection of prisoners of war (a subject earlier dealt with in a Hague Convention of 1907), providing that belligerents must treat prisoners humanely, supply information about them, and permit visits to prison camps by representatives of neutral states.

After World War II, because some belligerents had abused the principles contained in the earlier conventions, it was decided to extend and codify the existing provisions in an International Red Cross conference in Stockholm held Aug. 23–30, 1948. The conference developed four conventions which were approved in Geneva on Aug. 12, 1949: (1) Convention for the Amelioration of the Condition of the Wounded and Sick in Armed Forces in the Field, (2) Convention for the Amelioration of the Condition of the Wounded, Sick, and Shipwrecked Members of Armed Forces at Sea, (3) Convention Relative to the Treatment of Prisoners of War, and (4) Convention Relative to the Protection of Civilian Persons in Time of War.

The first two conventions were elaborations of the principle of the neutralization of the sick and wounded outlined above. The convention covering prisoners of war further developed that of 1929, requiring humane treatment, adequate feeding, and delivery of relief supplies and forbidding pressure on prisoners to supply more than a minimum of information.

The provisions of the fourth convention contained little that was not established in international law prior to World War II. The disregard of humanitarian principles during that conflict, however, made a restatement and reaffirmation timely. The convention contained detailed provisions for the protection of individuals falling under the jurisdiction of a belligerent. The following practices were forbidden: deportation of individuals or groups, regardless of motive; the taking of hostages; outrages upon personal dignity; torture; collective punishment and reprisals; the unjustified destruction of property; and discrimination in treatment on the basis of race, religion, nationality, or political grounds.

In the decades following World War II, the growing number of anticolonial and insurrectionary wars threatened to render the Geneva conventions obsolete. After four years of negotiation under the sponsorship of the Red Cross, an international conference on June 8, 1977, approved two protocols to the 1949 conventions. These extended protection under the Geneva and Hague conventions to guerrilla combatants fighting wars of "self-determination" or civil wars in which they exercised "control" over significant measures of territory.

More than 150 nations (including the United Kingdom and the United States) have become parties to the 1949 conventions, but only slightly more than half that number have signed the 1977 protocols (the United Kingdom and the United States have not).

**Genève** (French), English GENEVA, German GENÈVE, southwestern Switzerland. The *canton* lies between the Jura Mountains and the Alps and consists mainly of its capital, the city of Geneva (Genève). It is one of the smallest *cantons* in the Swiss Confederation. Bordering on Vaud *canton* for 3.5 miles (5.5 km) in the extreme north, it is otherwise surrounded by French territory—the *département* of Haute Savoie to the south and that of Ain west and north. The *canton* is drained by the Rhône River from east to west and then along its southwest edge, and by the turbid L'Arve River, which flows from Mont Blanc to join the Rhône within the city of Geneva.

Admitted into the Swiss Confederation in 1815, Genève was increased in 1815–16 by adding to the old territory belonging to the city 16 communes (to the south and east) ceded by Savoy and 6 communes (to the north) from the French district of Gex. The population, about one-half Roman Catholic and two-fifths Protestant, is primarily French-speaking.

Industry is concentrated in the city of Geneva and its suburbs. Market gardens, vineyards, and orchards occupy a large proportion of the *canton's* soil, and cattle, horses, swine, goats, and sheep are raised. Area 109 square miles (282 square km). Pop. (1992 est.) 378,849.

**Geneviève**, SAINT, French SAINTE GENEVIÈVE, German SANKT GENOVEFA (b. c. 422, city, Nanterre, France?—d. c. 500, Paris; feast day January 3), patron saint of Paris, who allegedly saved that city from the Huns.

When she was seven, Geneviève was induced by Bishop St. Germain of Auxerre to dedicate herself to the religious life. On the death of her parents she moved to Paris, where she is said to have predicted the invasion of the Huns. When Attila threatened Paris (451), she persuaded the inhabitants to remain, assuring them that the attack would be inconsequential; Attila's army went on to Orléans, 70

miles (110 km) from Paris, and was defeated. Geneviève is reported to have had great influence over King Childeric I of the Salian Franks and, in 460, to have had a church built over the tomb of Saint Denis, patron saint of France.

She was buried in the Church of the Holy Apostles, popularly known as the Church of Sainte-Geneviève. During the French Revolution in 1793, her body was burned on the Place de Grève; the relics were enshrined in the Church of Saint-Étienne-du-Mont, where they still attract pilgrims.

**Genghis Khan**, Genghis also spelled CHINGIS, CHINGIS, JENGHIZ, or JINGHIS, original name TEMÜJIN, also spelled TEMUCHIN (b. 1155, or 1162, or 1167, near Lake Baikal, Mongolia—d. Aug. 18, 1227), Mongolian warrior-ruler, one of the most famous conquerors of history, who consolidated nomadic tribes into a unified Mongolia and extended his empire from China to Europe's Adriatic Sea.

A brief treatment of Genghis Khan follows. For full treatment, see MACROPAEDIA: Genghis Khan.

The leader of a destitute clan, Temüjin acquired a fighting force of 20,000 neighbouring tribesmen (according to the anonymous saga the *Secret History of the Mongols*, c. 1240) in order to settle an interclan feud. He broke with his rival, Jamuka; overcame all contenders, Mongolian and Tatar, through executions and forced service; and by 1206 was acknowledged as Genghis Khan ("Universal Ruler") of all Mongolian steppe people. Using more refined military tactics, he captured Peking (1215) and subjugated a declining China. He then led a savage devastation of the extensive Muslim empire of Khwarezm (now in Turkmenistan and Uzbekistan) about 1216–23 while his generals raided Iran and Russia. Learning the importance of towns and agriculture from his subjects, he improved his governmental structure.

Genghis Khan's idea of the state was simple: the nomad warrior elite should remain in the steppes, drawing tribute from the conquered civilized kingdoms. But this concept could not withstand two corrosive trends: the nomads split into groups, each facing toward the subject state (China, Iran, etc.) from which it drew tribute; and in each group those who had to be detached for garrison and administrative service tended to be corrupted (or civilized) by their subjects.

**genie** (spirit): see jinni.

**genius** (Latin: "begetter"), plural GENII, in classical Roman times, an attendant spirit of a person or place.

In its earliest meaning in private cult, the *genius* of the Roman housefather and the *iuno*, or *juno*, of the housemother were worshiped. These certainly were not the souls of the married pair, as is clear both from their names and from the fact that in no early document is there mention of the *genius* or *iuno* of a dead person. The *genius* and *iuno* were probably the male and female forms of the family's, or clan's, power of continuing itself by reproduction, which were in the keeping of the heads of the family for the time being and passed at death to their successors. In this as in all forms of his cult, the *genius* was often conceived as appearing in the form of a snake, although he is also shown in art as a young man, generally engaged in sacrificing. At every wedding a bed, the *lectus genialis*, was made for the *genius* and *iuno* of the husband and wife, and its presence in the house was a sign of matrimony.

Owing to the rise of individualism and also to the prevalence of Greek ideas concerning a guardian spirit, or *daimon*, the *genius* lost its original meaning and came to be a sort of personification of the individual's natural desires and appetites. Hence the phrases *indulgere ge-*

*nio, genium defrudare*, signifying, respectively, to lead a pleasurable life, and to lead a stingy life. The development, however, did not stop here. The *genius* came to be thought of as a sort of guardian angel, a higher self; and, as the Greek *daimon* was sometimes rationalized into the individual's character or temper, so also the poet Horace half-seriously said that only the *genius* knows what makes one person so different from another, adding that he is a god who is born and dies with each one of us. This individual *genius* was worshipped by each individual, especially on his birthday. A few inscriptions even mention the *genius* of a dead person, as Christian epitaphs sometimes speak of his angel.

To show reverence for the genius of another or to swear by it was a mark of deep respect; hence, it is not unnatural that the *genius* of Augustus and of his successors formed objects of popular cult. Thus, to worship the *genius Augusti* avoided affronting the feeling against worshipping any living emperor, which remained fairly strong in Italy; for, of course, all *genii* were divine and might properly be worshipped.

As with the Greek *daimones*, there was a vast variety of *genii*, or guardian spirits—those of places, *genius loci*, including buildings (*genius balnearum*, etc.), and of corporations of all sorts, from the state (*genius populi Romani*) to small bodies of troops, guilds of tradesmen, and so forth. A very curious development is that one sometimes heard of the *genius* of a god, even of Jupiter, or of the *iuno* of a goddess.

**genius**, in psychology, a person of extraordinary intellectual power. The word *genius* is used in two closely related but somewhat different senses. In the first sense, as popularized by U.S. psychologist Lewis M. Terman, *genius* refers to high intellectual ability as measured by performance on a standardized intelligence test. The exact intelligence quotient designating *genius* varies. Terman set the intelligence quotient for "potential *genius*" at 140 or over, a level reached by about 1 in 250 of the general population. This seemed insufficiently stringent to some writers, who set a higher standard. In any event, *genius* here means simply high intellectual ability and refers to potentiality rather than to attainment. In this sense, the term may be used to characterize children who have not yet had an opportunity to gain eminence by achievement. A growing and probably more practicable usage is to refer to children of this sort as "gifted" and to make a distinction between first-order gifted children, those in the upper 0.1 percent of the general population, and second-order gifted children, those in the upper 10 percent of the remaining population.

In the second and more popular sense, as derived from work of the 19th-century British scientist Sir Francis Galton, "genius" is used to designate creative ability of an exceptionally high order as demonstrated by actual achievement, always provided that such achievement is not merely of transitory value or the result of accident of birth, as in the case of hereditary rulers. *Genius* is distinguished from talent both quantitatively and qualitatively. Talent refers to a native aptitude for some special kind of work and implies a relatively quick and easy acquisition of a particular skill. *Genius* involves originality, creativeness, and the ability to think and work in areas not previously explored and thus to give the world something of value it would not otherwise possess. Although geniuses have usually left their unique mark in a particular field, studies of the early development of these people appear to show that their general intelligence is also exceptionally high.

There have been a variety of attempts to explain the nature and source of *genius*. One theory holds that the *genius* belongs to a separate

psychobiological species, differing as much from ordinary man in his mental and emotional processes as man differs from the ape. Another theory looks upon *genius* as closely related to neurosis and psychosis. The Italian criminologist Cesare Lombroso is perhaps the most widely cited among those who held or hold this point of view. Although modern psychoanalytic theory would also hold that *genius*, like neurosis and psychosis, has its source in basic conflict between the self and environment, in the *genius* these conflicts are resolved in such a way that the symptoms and products are socially useful and valued. Investigations indicate that the *genius* is actually somewhat less prone to mental disorders, physical weakness, and bodily deformities than are people in general. Children who show exceptionally high general intelligence of the sort that may be classified as "gifted" or "potential *genius*" are on the average superior to other children in physique and health and in emotional and social adjustment.

Galton, who inaugurated the systematic study of *genius*, formulated the theory that *genius* is a very extreme degree of three combined traits—intellect, zeal, and power of working—that are shared by all persons in various "grades." In his *Hereditary Genius* (1869), he presented the first clear statistical evidence that *genius*, as measured by outstanding accomplishment, tends to run in families. Since then, scientists have differed over how much biological heredity, as distinct from education and opportunity, is responsible for the great differences in achievement of different individuals. The consensus is, however, that *genius* is a function of both hereditary and environmental factors. The original potentiality for exceptional achievement comes from heredity, but whether or not this potentiality is brought to fruition depends, at least to some extent, upon opportunity and training. *See also* gifted child; prodigy.

**genizah**, also spelled GENIZA (Hebrew: "hiding place"), plural GENIZOT, GENIZOTH, or GENIZAHs, in Judaism, a repository for time-worn sacred manuscripts and ritual objects, generally located in the attic or cellar of a synagogue. In the Middle Ages most synagogues had a *genizah*, because ceremonial burial (often with the remains of a pious, scholarly Jew) was thought to be the only fitting manner of disposing of sacred documents. Countless sacred manuscripts—called *shemot* ("names") because they contained the name of God—were thus left to gather dust or to disintegrate slowly.

In 1896 Solomon Schechter investigated a *genizah* in the old Ezra synagogue in Cairo. In time, some 90,000 manuscripts were uncovered there, a cache so priceless that biblical scholars subsequently referred to the site simply as "the *genizah*." This vast collection of liturgical, legal, commercial, and literary documents—among them a fragment of the original Hebrew text of Ecclesiasticus—generally revolutionized the study of the medieval history of Palestinian and Middle Eastern Jewry. Schechter's conclusions regarding a Zadokite sect were confirmed years later, after the discovery (late 1940s and '50s) of the Dead Sea Scrolls. The scrolls were found in caves that apparently also served as *genizot*. The manuscripts from the Cairo *genizah* are now preserved in many of the great libraries of the world.

**Genji monogatari** (Japanese literature): *see* Tale of Genji, The.

**Genk**, formerly GENCK, municipality, Limburg province, northeastern Belgium, on the edge of the Kempenland (Campine) Plateau, north of Liège. Formerly a market centre and holiday resort with scenic marshes and woods (including the Bokrijk Nature Reserve), it has become industrialized with the discovery (be-

fore World War I) of rich coalfields in the Kempenland. Metallurgy and automobile assembly are now major economic factors, and natural gas (*grison*) is a local resource. Pop. (1982) mun., 61,643.

**Genkū** (Buddhist leader): *see* Hönen.

**Gennadios II SCHOLARIOS** also spelled GENNADIUS II SCHOLARIUS, original name GEORGIOS SCHOLARIOS (b. c. 1405, Constantinople—d. c. 1473), first patriarch of Constantinople (1454–64) under Turkish rule and the foremost Greek Orthodox Aristotelian theologian and polemicist of his time. Scholarios became expert in European philosophy and theology and was called "the Latinist" derisively by his colleagues. He also taught and commented on Aristotelian and Neoplatonic texts, the chief expressions of classical Greek realism and idealism, respectively.

An imperial judge and lay preacher at the court of the Byzantine emperor John VIII Palaeologus, Scholarios was named a theological consultant to the general Council of Florence (1439) when the Greek Byzantine Church reluctantly consented to a union with the West in order to win military support against the advance of the Ottoman Turks. Later, in Constantinople, Scholarios repudiated the council's statement of doctrinal compatibility between Eastern and Western churches. He assumed leadership of the anti-unionist faction that proclaimed Orthodoxy's absolute autonomy and fundamental differences with Western Christianity. Out of favour with Emperor Constantine XI Palaeologus (1449–53), Scholarios became a monk at Constantinople's monastery of Pantocrator. When that city fell to the Ottoman Turks, May 1453, he was captured by a hospitable Muslim then invited to assume the vacant patriarchate by Sultan Mehmed II (1451–81) in order to stabilize the political situation. He was invested with ecclesiastical insignia and political authority as head of the Greek population, and the consequent treaty governed Greek Orthodox and Turkish relations for nearly 500 years. He helped persuade the Sultan to adopt a more conciliatory policy toward Christian peoples under Islamic political control.

Scholarios' 10-year patriarchal office was twice interrupted by Greek-Arab tensions, and he finally abdicated and retired to the Prodromos monastery at Seres (near modern Thessalonica [Thessaloniki], Greece). There he produced a wealth of theological and philosophical literature, including commentaries, on the works of Thomas Aquinas (unusual for an Eastern theologian); polemical tracts supporting Aristotelian thought; and many other compositions in liturgy, ethics, and poetry.

**Gennadius I OF CONSTANTINOPLE, SAINT** (d. 471, Constantinople; feast day August 25), Byzantine theologian, biblical exegete, and patriarch, a champion of Christian Orthodoxy who strove for an ecumenical (Greek: "universal") statement of doctrine on the person and work of Christ to reconcile the opposing Alexandrian (Egyptian) and Antiochene (Syrian) theological traditions.

Abbot of a monastery in Constantinople, Gennadius became patriarch in 458 and, with the counsel of Pope Leo I (440–461), proceeded against the Monophysites (*q.v.*) and deposed their titular head, Bishop Timotheus Aelurus of Alexandria. To counter any Monophysite interpretation of the dogmas promulgated at Ephesus against the Nestorian heresy (*see* Nestorians), Gennadius composed a sharp critique of Cyril of Alexandria's anathemas, written against the empirically oriented school of Antioch; indeed, he charged Cyril with blasphemy for identifying Christ's human ac-

tions with divinity. Moreover, to demonstrate his own orthodoxy, he wrote a commendation of Pope Leo's celebrated letter of 449 to Patriarch Flavian of Constantinople, delineating for both the Latin and the Greek churches the authoritative statement on Christ's nature and identifying the degrees of erroneous interpretation; this definitive expression became the norm for the general Council of Chalcedon.

Only parts of Gennadius' biblical commentaries on the Old Testament book of Genesis and Letter of Paul to the Romans are extant. His contemporaries esteemed him as a scholarly man of letters and a sincere churchman dedicated to reform of simoniacal practices. In the Eastern Orthodox church Gennadius is revered as a saint.

**Gennadius OF MARSEILLES** (fl. late 5th century, Marseille [now in France]), theologian-priest whose work *De viris illustribus* ("On Famous Men") constitutes the sole source for biographical and bibliographical information on numerous early Eastern and Western Christian authors.

Having read widely in Greek and Latin, Gennadius, between 467 and 480, drew up his continuation of the chronicle *De viris illustribus*, which had been initiated by St. Jerome after the identically titled classic model of the 2nd-century Latin historian Suetonius. Gennadius' version comprised 91 biographies of late 4th- and 5th-century Greek and Latin theological writers; the work was augmented to 100 biographies by later editors.

**Gennadius OF NOVGOROD** (d. after 1504), Russian Orthodox archbishop of Novgorod, Russia, whose leadership in suppressing Judaizing Christian sects occasioned his editing the first Russian translation of the Bible.

Named archbishop in 1485, Gennadius initiated a persecution of Christian Judaizers, a movement of zealots stressing the monotheistic element of the Jewish religion and promulgating anti-Trinitarian doctrine. Collaborating with the monastic reformer Joseph of Volokolamsk (Russia), he convoked three synods to counter the heretical sectarians and consciously imitated the model of the 15th-century Spanish Catholic Inquisition against nonconforming Jewish, Arab, and Protestant Christians. When the Judaizers began distributing their own versions of the Old Testament Psalms, Gennadius published the first complete translation of the Old and New Testaments into the Old Church Slavonic language. The translation, made from the Greek, Hebrew, and Latin versions, was completed with the help of a Croatian Dominican friar, Benjamin.

Because of Moscow's governmental policy of expropriating church property as punishment for Novgorod's separatist tendencies, Gennadius was forced to resign in 1504 and was imprisoned on suspicion of treason.

**Gennaro, SAINT:** see Januarius, Saint.

**Gennep, Arnold van,** in full CHARLES-ARNOLD KURR VAN GENNEP (b. 1873, Württemberg, Ger.—d. 1957), French ethnographer and folklorist, best known for his studies of the rites of passage of various cultures.

Although Gennep was born in Germany and had a Dutch father, he lived most of his life and received his education in France, his mother's native country. Gennep learned a remarkable number of languages (he knew Arabic and studied Egyptology) and thus could effectively use linguistic and philological facts in his ethnographic studies. Most of his work was done outside of, and occasionally in odds with, the academic community.

Gennep's major work was *Les Rites de Passage* (1909; *The Rites of Passage*), in which he systematically compared those ceremonies

that celebrate an individual's transition from one status to another within a given society. He found a tripartite sequence in ritual observance: separation, transition, and incorporation. Gennep offered interpretations of the significance of these rites as forms of social regeneration, based on such natural symbols as death and rebirth.

Gennep also made studies of European folklore, viewing folk literature and practices as aspects of a living culture rather than as remains of a dead one.

**Genes, Pierre-Gilles de** (b. Oct. 24, 1932, Paris, Fr.), French physicist, who was awarded the 1991 Nobel Prize for Physics for his discoveries about the ordering of molecules in various substances.

The son of a physician, Genes studied at the École Normale Supérieure ("Upper Normal School"). He was employed as an engineer at the French Atomic Energy Commission (1955-61) and then was a professor with the Orsay Liquid Crystals Group of the University of Paris (1961-71) and a professor at the Collège de France (from 1971).

De Genes's research from the 1960s on focused mainly on crystals, in both inorganic and organic contexts, with related studies and analyses of other materials, as he tried to determine their molecular behaviour in ordered and disordered states. A few of the judges on the Nobel committee described him as "the Isaac Newton of our time" in having successfully applied mathematics to generalized explanations of several different physical phenomena.

**Genoa, Italian GENOVA, ancient (Latin) GENUA,** city and Mediterranean seaport in northwestern Italy. It is the capital of Genoa *provincia* and of Liguria *regione* and is the centre of the Italian Riviera. Its total area is 93 square miles (240 square km).

**Geography.** Located about 75 miles (120 km) south of Milan on the Gulf of Genoa, the city occupies a narrow coastal plain and the western slopes of the Apennine Mountains. Genoa has a mild Mediterranean climate.

Shipbuilding is the major industry; other industries produce petroleum, textiles, iron and steel, locomotives, paper, sugar, cement, chemicals, fertilizers, and electrical, railway, and marine equipment. Genoa also is a major centre for finance and commerce. The port of Genoa leads all other Italian ports in volume of passengers and freight traffic and is the main source of city income.

Genoa was the birthplace of Christopher Columbus (1451), who embodied the active maritime tradition of the city. It is noted for its many examples of medieval, Renaissance, Baroque, and Gothic architecture. The Ducal Palace, San Lorenzo Cathedral, Church of San Matteo, and Palazzo San Giorgio are some of the most important historical monuments. The Palazzo Bianco and the Palazzo Rosso are the two largest picture galleries; Choissone Museum of Oriental Art and the Cathedral Treasury have extensive medieval collections. The University of Genoa (founded 1471) is an important centre of higher learning in northern Italy. The city also has several commercial colleges and a school of navigation.

Genoa is linked with the major cities of Italy, France, and Switzerland by railway and highways. Its port serves as the chief outlet for the agricultural and industrial products of northern Italy and much of central Europe. Cristoforo Colombo International Airport, situated 4 miles (6.5 km) west of the city, provides domestic and international flights.

**History.** In ancient times, what probably began as a Ligurian village on the Sarzano Hill overlooking the natural port (today Molo Vecchio) prospered through contacts with the Etruscans and the Greeks. As a flourishing Roman *municipium* it became a road junction, a military port, and a market of the

Ligurians. After the fall of the Roman Empire, followed by invasions of Ostrogoths and Lombards, Genoa long existed in comparative obscurity as a fishing and agrarian centre with little trade. By the 10th century, however, the general demographic and economic upswing of Europe brought fresh opportunity and enabled the Genoese to answer the challenge of Muslim raids vigorously. A Fatimid fleet stormed and sacked the town (934 or 935), but the Genoese raised their walls anew and counterattacked under the leadership of their bishop and of the local viscounts. Soon, Genoese merchant ships were trading briskly in the western Mediterranean and calling at Palestinian seaports.

Before 1100 a voluntary association (*compagna*) of all citizens who would contribute arms, capital, or labour to the life of the community generated the independent commune of Genoa; executive power was vested in a number of "consuls" yearly elected by a popular assembly. The ruling class consisted chiefly of petty noblemen and affluent bourgeois. Maritime commerce was the dominant activity. During the 12th and 13th centuries Genoa played a leading role in the commercial revolution that Europe was undergoing. It became a town of about 100,000 inhabitants, a naval power dealing on equal terms with the greatest monarchies, and a commercial centre rivaled only by Venice in the Levant trade and competing with other Italian towns in trade with western Europe. Eastern spices, dyestuffs and medicaments, Western cloth and metals, African wool, skins, coral, and gold were the main articles of a very diversified international commerce. Banking and shipbuilding flourished, and the textile industry began.

At the same time, the Genoese brought all of Liguria, most of Corsica, and northern Sardinia under their direct or indirect control and founded self-governing commercial colonies all around the Mediterranean coast. Many of these colonies were the result of Genoese participation in the Crusades and of shorter campaigns by the Genoese alone in Spain, Africa, and the Levant, but some were established peacefully. They ranged in size from individual buildings to walled suburbs of towns and, eventually, entire islands or districts of coastal land.

The collapse of the Crusaders' states, with their Genoese enclaves, in the late 13th century was amply compensated by Genoa's alliance with the Byzantine Empire under the Treaty of Ninfes (1261), which paved the way for a great expansion in the Black Sea. Pera (modern Beyoğlu), the Genoese independent suburb of Constantinople, gradually outstripped the Byzantine capital in economic development, and Kaffa (modern Feodosiya) became the capital of a broad stretch of the Crimean coast ruled by the Genoese. Many Aegean islands became independent Genoese principalities.

Throughout this period internal political strife in Genoa was almost incessant, but it did not seriously hamper the progress of the community. The state was managed as a business affair, to the common profit of the ruling families—such as the Spinola, Fieschi, Grimaldi, and Doria—and generally to the advantage of the whole population. The form of government changed and evolved, so that by the second half of the 13th century "captains of the people" were governing with unlimited tenure and with the support of the guilds. The living standard of the entire population constantly improved. Municipal and family pride led to the construction of splendid buildings, wharves, bridges, and churches.

Genoa's political zenith was marked by a crushing naval victory over the Pisans at Meloria (1284) and a less decisive one over the Venetians at Curzola (1298). In the same period, maritime trade reached its peak. During the 14th and 15th centuries, however, the

whole of Europe was in a profound material and moral crisis. In Genoa class and party struggles kept the government in perpetual turmoil, and public finances were ruined by war. The election of native doges after the Venetian model, beginning with that of Simone Boccanegra in 1339, was a vain attempt to solve the political problem.

After emerging from periods of French domination (1394–1409) and Milanese overlordship (1421–35), Genoa was no longer a great power. Corsica was in perennial revolt; Sardinia was overrun by the Aragonese; the Levant colonies, which had become virtually independent of the motherland, were conquered by the Egyptians or the Turks. Only the mainland domain (that is, Liguria proper) was successfully held.

After a period of successive Milanese, French, and Spanish intrusions, Andrea Doria, scion of an old noble Genoese family, forced through a new constitution (1528) and restored his city to orderly government under biennial doges and an oligarchy of the old and new noble merchants; he also made Genoa politically a satellite of Spain, trying to ensure that Genoa would be a privileged exploiter of the new and vast Spanish empire in the New World. The result was a partial economic recovery in the 16th and 17th centuries.

As the fortunes of Spain and the Italian states declined, Genoa's did so likewise. By the mid-18th century, trade had sunk to its lowest level. In 1768, by the Treaty of Versailles, the republic ceded to France its last overseas possession, Corsica.

In the French revolutionary and Napoleonic wars, the republic saw its neutrality violated by both sides. In 1797, under Napoleon Bonaparte's pressure, it was transformed into the Ligurian Republic, under a French protectorate. In 1805 Genoa was annexed by the French Empire. In November 1814 the Congress of Vienna awarded Genoa to the house of Savoy. Thereafter in the 19th century the merchant marine rapidly revived, and Genoese trade blossomed anew.

The unification of Italy in 1861 further broadened the scope of Genoese activity. Genoa, then Italy's greatest commercial port, vied with Marseille for supremacy in the Mediterranean and competed with the ports of the North Sea for the trade of Switzerland and central Europe; and when Genoa's share in the latter declined somewhat in the 20th century the difference was counterbalanced by the ever-increasing trade flowing to and from northern Italy. The university, into which pre-existing institutions of higher learning had been merged in 1803, became especially distinguished for teaching on economic and maritime subjects. Pop. (2000 est.) mun., 636,104.

**Genoa, Gulf of**, Italian GOLFO DI GENOVA, northern portion of the Ligurian Sea (an inlet of the Mediterranean Sea), extending eastward around the northwest coast of Italy for 90 miles (145 km), from Imperia to La Spezia. It receives the Magra, Roia, Centa, and Taggia rivers and includes the small gulfs of Spezia and Rapallo. The coastal region forms part of the Italian Riviera centred on Genoa (the gulf's main port); it is noted for its scenery, mild winter climate, and luxuriant subtropical vegetation. Resorts include Imperia, Savona, Rapallo, Sestri Levante, and La Spezia. The Gulf of Spezia, Italy's largest and best harbour, has been the site of the chief Italian naval station since the mid-19th century.

**genocide**, the deliberate and systematic destruction of a group of people because of their ethnicity, nationality, religion, or race. The term, derived from the Greek *genos* ("race," "tribe," or "nation") and the Latin *cide* ("killing"), was coined by Raphael Lemkin, a Polish-born jurist who served as an adviser to the U.S. Department of War during World War II.

Although the term itself is of recent origin, genocide arguably has been practiced throughout history. Twentieth-century events often cited as genocide include the 1915 Armenian massacres (*q.v.*) by the Turkish-led Ottoman Empire, the extermination of Jews, Roma (Gypsies), and other minorities by Nazi Germany during World War II, and the killing of Tutsis by Hutus in Rwanda in the 1990s.

In contemporary international law, the crime of genocide is part of the broader category of "crimes against humanity," which appeared in the Charter of the International Military Tribunal convened at Nürnberg, Ger., in 1945. The charter granted the tribunal jurisdiction to indict and try leaders of the Nazi regime for inhumane acts committed against civilians—as well as for acts of persecution on political, racial, or religious grounds. The momentum created by the subsequent Nürnberg trials (*q.v.*) led to the passage by the UN General Assembly of Resolution 96-1 (1946), which made the crime of genocide punishable under international law, and of Resolution 260-III (1948), which approved the text of the Convention on the Prevention and Punishment of the Crime of Genocide. The convention, which entered into force in 1951, has been ratified by more than 130 countries.

Article 2 of the convention defines genocide as "any of the following acts committed with intent to destroy, in whole or in part, a national, ethnical, racial or religious group, as such: (a) Killing members of the group; (b) Causing serious bodily or mental harm to members of the group; (c) Deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part; (d) Imposing measures intended to prevent births within the group; (e) Forcibly transferring children of the group to another group."

Although the convention has enjoyed near unanimous international support, it has often been criticized for excluding political and social groups from the list of possible victims of genocide. The first part of the convention's definition of genocide, known as the "intentionality clause," also is problematic. Two of the most common objections to it are that intent is difficult to establish and that it is difficult to locate within increasingly complex societal arrangements. In support of the first objection, some scholars have noted that governments do not openly admit to committing genocidal acts—a fact that is borne out in history. The Iraqi regime of Saddam Hussein, for example, portrayed its use of chemical warfare against the Kurds in the 1980s as an effort to reestablish law and order, and the Ottoman and successive Turkish governments asserted that the Armenians killed in the massacres were casualties of war. In response, defenders of the intentionality clause have argued that "a pattern of purposeful action" leading to the destruction of a significant part of the targeted group is enough to establish genocidal intent, irrespective of the reasons the perpetrator regime offers for its actions.

Supporters of the second objection have argued that an approach that focuses solely on intent ignores the "structural violence" of social systems in which vast political and economic disparities can lead to the total marginalization and even extermination of particular groups. Defenders of the intentionality clause respond that it is necessary for differentiating genocide from other forms of mass killings and for devising effective strategies to prevent it.

The genocide convention was the first legal instrument to disentangle the most heinous of crimes against humanity from the "war-nexus" requirement, which had limited the jurisdiction of the Nürnberg tribunal to cases in which a crime against humanity was committed in conjunction with a crime against interstate peace. Instead, the convention declared

that genocide was an international crime "whether committed in time of peace or in time of war." Moreover, the convention was the first UN legal instrument to stipulate that individuals can incur international criminal responsibility whether or not they act on behalf of a state. The convention can also serve, in accordance with Article 8, as the legal basis of enforcement measures ordered by the Security Council (the only UN organ that can authorize the use of force).

During the first 50 years after its ratification, the genocide convention lacked effective enforcement mechanisms. Although it stipulated that persons charged with genocide should be tried before an international penal tribunal or a tribunal of the state in which the crime was committed, no permanent penal tribunal existed at the international level until the early 21st century, and prosecutions at the domestic level were unlikely except in the rare case where a genocidal regime was overthrown and its officials prosecuted by a successor regime.

The genocide convention was first invoked before an international tribunal in 1993, when the government of Bosnia and Herzegovina argued before the International Court of Justice that the Federal Republic of Yugoslavia was in breach of its legal obligations under the convention. During the 1990s the international community became more vigorous in prosecuting alleged crimes of genocide. The UN Security Council established separate tribunals for Yugoslavia and Rwanda, both of which contributed to the clarification of the material elements of the offense of genocide as well as of the criteria establishing individual criminal responsibility for its commission. The Rwandan tribunal, for example, stated that genocide included "subjecting a group of people to a subsistence diet, systematic expulsion from homes and the reduction of essential medical services below minimum requirement." It also ruled that "rape and sexual violence constitute genocide . . . as long as they were committed with the specific intent to destroy, in whole or in part, a particular group, targeted as such"—as was the case in the Rwandan conflict, where the government, dominated by the Hutu ethnic group, organized the mass rape of ethnic Tutsi women by AIDS-infected men. On the critical issue of intentionality, the Yugoslav tribunal also ruled that genocidal intent can be manifest in the persecution of select groups of people as well as large ones.

On July 1, 2002, the Statute of the International Criminal Court (*q.v.*, ICC), adopted in 1998 in Rome, entered into force. The ICC's jurisdiction includes the crime of genocide, which the statute defines exactly as does the genocide convention. The establishment of the ICC—though without the participation of the United States, China, and Russia—was another indication of a growing international consensus in favour of vigorous and concerted efforts to suppress and punish the crime of genocide. (G.J.An.)

**Genoese lace**, bobbin lace made at Genoa, Italy, from the second half of the 16th century; it developed from the earlier knotted fringe called *punto a groppo*. The early laces (*merletti a piombini*, "laces made with lead weights") were used for the edging of ruffs and later of collars. Styles followed a pattern similar to needle-made lace in Venice, taking the form of deeply pointed "vandykes" (V-shaped points seen on collars in many 17th-century portraits by Anthony Van Dyck). These points began to

Genovese lace, first half of the 17th century; in the Institut Royal du Patrimoine Artistique, Brussels

give way about 1600 to round, scalloped edges. Genoa was famous also for its tape lace, made from flat but curving bobbin-made tape.

**genotype**, the genetic constitution of an organism. The genotype determines the hereditary potentials and limitations of an individual from embryonic formation through adulthood. Among organisms that reproduce sexually, an individual's genotype comprises the entire complex of genes inherited from both parents. It can be demonstrated mathematically that sexual reproduction virtually guarantees that each individual will have a unique genotype (except for those individuals, such as identical twins, who are derived from the same fertilized egg).

The actual appearance and behaviour of the individual—*i.e.*, the individual's phenotype (*q.v.*)—is determined by the dominance relationships of the alleles that make up the genotype, along with environmental influences.

**Genovese, Vito**, byname DON VITONE (b. Nov. 27, 1897, Rosiglino, Italy—d. Feb. 14, 1969, Springfield, Mo., U.S.), one of the most powerful of American crime syndicate bosses from the 1930s to the 1950s.

Genovese immigrated to New York City in 1913, joined local gangs, and in the 1920s and '30s was Lucky Luciano's second-in-command in narcotics and other rackets. In 1937 he escaped to Italy to avoid prosecution on a murder charge and became a friend of Benito Mussolini. After the war, Genovese was returned to the United States to face trial on the murder charge. After a key witness against him died, Genovese was set free and reestablished his power in New York City. Finally, in 1958, the federal government indicted him for smuggling and distributing narcotics, and in 1959 he was convicted and sentenced to federal prison for 15 years. From prison he continued to rule and to order the killing of rivals.

**Genovesi, Antonio** (b. Nov. 1, 1712, Castiglione, Republic of Venice [Italy]—d. Sept. 23, 1769, Naples, Republic of Naples), Italian philosopher and economist whose proposals for reforms in the Kingdom of Naples combined humanist ideas with a radical Christian metaphysical system.

Ordained a priest in 1737, Genovesi went to Naples in 1738 and in 1741 was appointed to teach metaphysics in the university there. Two years later he wrote the first volume of his *Dis-*

*ciplinarium Metaphysicarum Elementa*, 5 vol. (1743–52; "Elements of the Discipline of Metaphysics"). In 1748, charged with propagating heretical ideas in his *Elementa*, he decided not to publish his companion work on theology; it appeared after his death as *Universae Christianae Theologiae Elementa* (1771; "Elements of Universal Christian Theology").

His fortunes improved in 1753, when he dedicated a discourse on agriculture to Bartolomeo Intieri, who founded at Naples the first European chair of "commerce and mechanics" (*i.e.*, political economy) in 1754 and directed that Genovesi be its first occupant. There he wrote and lectured. Genovesi's mercantilist view of economics is distinguished by a brilliant analysis of demand, by his high valuation of labour, and by his efforts to reconcile free competition with protectionist policies. In political philosophy he held that ecclesiastical authority should not extend beyond strictly spiritual matters.

**Genpachi**: see Okumura Masanobu.

**genre painting**, painting of scenes from everyday life, of ordinary people in work or recreation, depicted in a generally realistic manner. Genre art contrasts with that of landscape, portraiture, still life, religious themes, historic events, or any kind of traditionally idealized subject matter. Intimate scenes from daily life are almost invariably the subject of genre painting. The elimination of imaginative content and of idealization focuses attention upon the shrewd observation of types, costumes, and settings.

The term arose in 18th-century France to describe painters specializing in one kind (*genre*) of picture, such as flowers or animals or middle-class life, and was originally used derogatively by advocates of the ideal or grand manner in art. By the late 19th century, when the critic Jakob Burkhardt wrote *Netherland Genre Painting* (1874), the term was more approving and also restricted to its current sense. The term is still most popularly used to describe the works of such 17th-century Dutch and Flemish painters.

**genro**, Japanese GENRŌ ("principal elders"), extraconstitutional oligarchy that dominated the Japanese government from the promulgation of the Meiji Constitution (1889) to the early 1930s. The genro were men who had played a leading role in the 1868 Meiji Restoration (the overthrow of feudal rule) and in the organization of the new government that followed this revolution. After the constitution was promulgated, these men became personal counselors to the throne, a position that allowed them virtually to run the bureaucracy, though they rarely assumed overt power for themselves. Important figures in the group were Itō Hirobumi, framer of the constitution; Yamagata Aritomo, who modernized the army; and Saionji Kimmochi, the last survivor and most liberal of the group.

**Genroku period**, in Japanese history, era from 1688 to 1704, characterized by a rapidly expanding commercial economy and the development of a vibrant urban culture centred in the cities of Kyōto, Ōsaka, and Edo (Tokyo). The growth of the cities was a natural outcome of a century of peaceful Tokugawa rule and its policies designed to concentrate samurai in castle towns. Whereas Edo became the administrative capital of the Tokugawa shogunate, Ōsaka served as the country's commercial hub, and rich Ōsaka merchants generally were the ones who defined Genroku culture. Free of the rigid codes that restricted samurai, townsmen could spend their leisure in the pursuit of pleasure, while their profits created a cultural explosion. The bunraku puppet theatre and kabuki developed into a high dramatic art with the works of the playwrights Chikamatsu Monzaemon and

Takeda Izumo. The stories of Ihara Saikaku humorously depicted urban life, while haiku poetry was perfected by Matsuo Bashō. In art the wood-block prints (*ukiyo-e*) of Hishikawa Moronobu rank among the earliest masterpieces. Other notable pieces of wood-block art, including those of Suzuki Harunobu, who developed the multicolour technique, soon followed. The Genroku period set the standards for an urban culture that continued to flourish throughout the Tokugawa period.

**gens**, plural GENTES, ancient Roman kinship grouping whose members claimed descent from a common male ancestor. The descendants revered this ancestor and identified themselves by using his name as their second name (or *nomen*)—*e.g.*, Caius Valerius Catullus. The gens was exogamous—marriage with another member of the gens was discouraged.

The term gens was introduced into anthropology in 1877 by the American anthropologist Lewis Henry Morgan. Morgan intended gens to replace the term clan. The word clan, however, is increasingly used, except in the United States. See also clan.

**Genscher, Hans-Dietrich** (b. March 21, 1927, Reideburg, near Halle, Ger.), chairman (1974–85) of the West German Free Democratic Party (Freie Demokratische Partei; FDP) and foreign minister (1974–92).

During World War II Genscher was drafted into the German armed services and was a prisoner of war at war's end. After his release he settled in what became East Germany, studying law and economics and then becoming a junior barrister in 1949. In 1952 he fled to the West and soon joined the Free Democratic Party, rising quickly in its official ranks in Bremen. In 1965 he was elected to the Bundestag as a deputy for North Rhine-Westphalia. Beginning in 1969, the Free Democrats gave their support to the dominant Social Democrats in a coalition government, and Genscher became minister of the interior. Five years later he won the chairmanship of his party and the foreign ministry in the government. In 1982 the Free Democrats switched their coalitionist allegiance to the Christian Democrats, who took over the government; Genscher continued as foreign minister.

Genscher strongly favoured better relations with the Soviet Union and the old Eastern bloc. In 1989–90 he worked vigorously for German reunification and became the first foreign minister of the unified Germany. He resigned from the cabinet in 1992 but remained a member of the Bundestag until his retirement from politics in 1998.

**gentian** (genus *Gentiana*), any of about 400 species of annual or perennial (rarely biennial)

Pine-barren gentian (*Gentiana autumnalis*)

© John Bova—The National Audubon Society Collection/Photo Researchers

flowering plants of the family Gentianaceae distributed worldwide in temperate and alpine regions, especially in Europe and Asia, North and South America, and New Zealand. They are especially a notable feature of mountain regions, where the moisture-loving plants have access to underground water in summer and snow cover in winter. Gentian flowers are typically blue (hence "gentian blue") or purplish blue but may be purple, violet, mauve, yellow, white, or even red; the four or five petals are usually united into a trumpet, funnel, or bell shape. The flowers have been used in the making of dyes, especially *Gentiana pneumonanthe*, a source of blue dye. The tough fibrous roots were once used herbarily for putative alimentary cures, and the name gentian derives from Gentius, king of ancient Illyria and alleged discoverer of the plant's medicinal value. *Gentiana lutea*, the yellow gentian, is found in Europe and western Asia and is the source of a flavouring in liqueurs.

Other species, such as the fringed gentians, formerly included in *Gentiana*, are now referred to as *Gentianella* (about 125 species) and *Gentianopsis* (about 15 species). The gentian family, Gentianaceae, includes more than 80 genera and 1,000 species.

**Gentianales**, gentian order of flowering plants, belonging to the class Magnoliopsida (the dicotyledons). It is composed of 6 families and approximately 5,500 species, although up to 11 families and 12,000 species have been recognized, depending on the classification used. Four large families account for most species and are important as the source of ornamental plants, drugs, and, to a lesser extent, fibres and rubber.

Trees, shrubs, and vines are more characteristic of this order than are annual or perennial plants. The majority of species are native to the tropics or warmer temperate regions; only the gentian family (Gentianaceae) is found mainly in the North Temperate Zone. Most members of the Gentianales inhabit forests where humidity is high and soil composition favourable for growth.

The members of the gentian order have a leaf blade that is a single unit (simple) and leaves that are opposite (two per node or joint). Some members secrete sticky substances from glandular appendages or the stipules. The flowers are usually showy, alike in size and shape (regular), and the petals are usually fused. The carpels are normally united to form a compound ovary that is positioned above the flower petals. The flowers contain multiple stamens. Ovules possess one integument (early stage of seed coat), and the nucellus (the nutritive tissue beneath the integument) is one-layered. The fruits are usually capsules or follicles, contain numerous seeds, and are winged or comose (tufted) to aid in wind-dispersal.

The Loganiaceae, a largely tropical family, contains about 21 genera and at least 500 species. Seeds of the 40-foot (12-metre) tree of south Asia, *Strychnos nux-vomica*, yield the alkaloids strychnine and brucine. The former is a poison often used to kill rodents, and the latter is an additive in lubricants. Alkaloids produced by *S. ignatii*, the Saint-Ignatius-bean of the Philippines, have been used to treat cholera. *S. spinosa* of southern Africa produces a yellow berry with edible pulp. *S. toxifera* is a source of curare. About 70 species of Loganiaceae are ornamentals.

Latex tubes in the stems of the dogbane family, Apocynaceae, produce a milky juice (a feature shared with the milkweed family, Asclepiadaceae). Up to 200 genera and 2,000 species have been attributed to the Apocynaceae, although one classification places the numbers closer to 155 genera and 1,000 species. Most are shrubs or trees of tropical or subtropical regions. At least 33 genera are under cultivation. Members of Apocynaceae include the common oleander, the periwinkle

(*Vinca minor*), and *Funtumia elastica* (grown specifically for its rubber-producing latex).

The milkweed family, Asclepiadaceae, is characterized by specialized, oblong pollen masses (the pollinia) and by latex in all vegetative parts. Its 250 genera and 2,000 species have a wide distribution, particularly in the tropics. The floss of the milkweed seed has been used as a low-grade substitute for kapok and is useful for insulation.

Many members of the Asclepiadaceae are ornamental. They include the butterfly weed (*Asclepias tuberosa*) and the waxplant (*Hoya carnosa*). Many cultivars of the cactuslike carrion flower *Stapelia*, an African succulent, are available. Petals of many species are foul-smelling and yellowish, with bands of darker colours.

Flowers of certain members of the gentian family, or Gentianaceae, display some of the purest blues in the plant kingdom. This family of 75 genera and 1,100 species is composed of herbs distributed chiefly in North Temperate regions. Many gentians favour wet woods and meadows as habitats; others favour rocky, alpine conditions. Their tubular corollas vary from wide-open to bell forms and to completely closed ones. *Gentiana lutea* of Asia Minor is prized for its yellow flowers; its root is locally considered medicinal and is used to flavour vermouth.

In all families of this order, seeds are produced in great profusion and are the most effective method of reproduction. The Indian hemp (*Apocynum*) and several milkweeds, however, form colonies by means of rhizomes, from which new plants arise to propagate the species vegetatively.

In most genera, clusters of flowers (inflorescences) are arranged on somewhat elongated stems. The eventual form depends on the amount of branching and the length of stalk of each flower. Nearly flat-topped clusters are the general rule, with the oldest flower at the top or toward the centre. A representative flower of the gentian order will have parts in fours or fives. Following pollination and fertilization, the ovule becomes the seed and the ovary the fruit. In some families, the fruit ripens dry—as a capsule in gentians or as a one-carpel unit (the follicle) in milkweeds. Fruits in the logania family ripen as either fleshy berries or drupes (with stony internal layer). Berries of coffee are representative of many madders.

**Gentil, Émile** (b. April 4, 1866, Volmunster, Fr.—d. March 30, 1914, Bordeaux), French colonial administrator who explored the areas of the present Congo, Central African Republic, and Chad and helped establish French rule in equatorial Africa.

A naval officer, Gentil led an expedition from the French Congo down the Shari (Chari) River to Lake Chad in 1895–97, establishing a French protectorate over the sultanate of Bagirmi. In 1900 he was made governor of the Shari region and was one of the leaders of the campaign against the Muslim leader Râbiḥ az-Zubayr, whose defeat he described in *La Chute de l'empire de Rabah* (1902; "The Fall of Râbiḥ's Empire"). From 1904 to 1908 Gentil served as governor of the French Congo.

**Gentile**, person who is not Jewish. The word stems from the Hebrew term *goy*, which means a "nation," and was applied both to the Hebrews and to any other nation. The plural, *goyim*, especially with the definite article, *ha-goyim*, "the nations," meant nations of the world that were not Hebrew. The Latin versions of the Bible translated *goyim* as *gentes* (singular: *gens*), or *gentiles*. In modern usage, "Gentile" applies to a single individual, although occasionally (as in English translations of the Bible) "the Gentiles" means "the nations." In postbiblical Hebrew, *goy* came to mean an individual non-Jew rather than a "nation." Because most non-Jews in the West-

ern world were Christians, Gentile came to be equated with Christian. Strictly speaking, however, any non-Jew is a Gentile.

In the Church of Jesus Christ of Latter-day Saints (Mormons), whose members regard themselves as the true Hebrews, "Gentile" denotes any person, including a Jew, who is not a Mormon.

**Gentile** DA FABRIANO, original name NICCOLO DI GIOVANNI DI MASSIO (b. c. 1370, Fabriano, Papal States [Italy]—d. 1427, Rome), foremost painter of central Italy at the beginning of the 15th century, whose few surviving works are among the finest examples of the International Gothic style.

An early signed work by Gentile has stylistic affinities with Lombard painting and suggests that he was trained in the Lombard school. In 1409 Gentile was commissioned to decorate the Doges' Palace in Venice with historical frescoes, which were later completed by Il Pisanello. In 1414–19 Gentile was in Brescia working for Pandolfo III Malatesta. His final important cycle of frescoes was begun in Rome in the Church of St. John Lateran shortly before his death. As with the frescoes in Venice, they were completed by Il Pisanello.

His surviving masterpiece, the "Adoration of the Magi," was completed in 1423 for the Church of Santa Trinità, in Florence. Its graceful figures are clothed in velvets and rich brocades, and the Magi are attended by Oriental retainers, who look after such exotic animals as lions and camels. Its delicate linearity and vibrant colours enhance the effect of rich exoticism. The decorativeness of its elegant, courtly style continued to influence Florentine artists throughout the century and presented a counterattraction to the austere realism introduced by Masaccio. Gentile also produced a number of Madonnas, such as the altarpiece known as the Quaratesi Polyptych (1425), which show the Mother and Child, regally clad, sitting on the ground in a garden.

**Gentile, Giovanni** (b. May 30, 1875, Castelvetro, Italy—d. April 15, 1944, Florence), major figure in Italian idealist philosophy, politician, educator, and editor, sometimes called the "philosopher of Fascism." His "actual idealism" shows the strong influence of G.W.F. Hegel.

After a series of university appointments, Gentile in 1917 became professor of the history of philosophy at the University of Rome. While writing *La filosofia di Marx* (1899;

Giovanni Gentile

By courtesy of the *Giornale critico della filosofia italiana*

"The Philosophy of Marx"), a Hegelian examination of Karl Marx's philosophy, he met Benedetto Croce, and from 1903 to 1922 the two men coedited the periodical *La Critica*. Gentile influenced Croce's philosophy and remained his friend until 1924, when a lasting disagreement arose over Gentile's embrace of Fascism.

As minister of education in the Fascist government of Italy from October 1922 to July

1924, Gentile carried out wide reforms. In 1925 he served as president of two commissions on constitutional reform, thus helping to lay the foundations of the Fascist corporate state. After acting as president of the Supreme Council of Public Education (1926–28) and as a member of the Fascist Grand Council (1925–29), he saw his political influence steadily decline. Perhaps his most important achievement was the *Enciclopedia Italiana* (first edition completed in 1936), which he began to plan in 1925 and edited until 1943. After the fall of Benito Mussolini in 1943, Gentile supported the Fascist Social Republic established by the Germans at Salò and was made the president of the Academy of Italy, in which post he served until his death at the hands of anti-Fascist communists.

Gentile's idealist philosophy denied the existence of individual minds and of any distinction between theory and practice, subject and object, past and present. According to him, all of these categories are merely mental constructs. Mind is the Absolute, and education is the process of revelation of the Absolute.

Gentile was highly esteemed by his students, whose views he helped to publicize through *Giornale critico della filosofia italiana* ("Critical Journal of Italian Philosophy").

In addition to his editions of Italian philosophers (including Giordano Bruno, Tommaso Campanella, Giambattista Vico, and Vincenzo Cuoco), Gentile wrote prolifically in education and philosophy. Among his works are *Le origini della filosofia contemporanea in Italia*, 4 vol. (1917–23); *La riforma dell'educazione* (1920; *The Reform of Education*); *La filosofia dell'arte* (1931; *The Philosophy of Art*); and *La mia religione* (1943; "My Religion"). His "actual idealism" is the subject of *Teoria generale dello spirito come atto puro* (1916; *The Theory of Mind as Pure Act*).

**Gentileschi, Artemisia** (b. 1593, Rome, Papal States [Italy]—d. 1652/53, Naples, Kingdom of Naples), Italian painter, daughter of Orazio Gentileschi, who was a major follower of the revolutionary Baroque painter Caravaggio. She was an important second-generation proponent of Caravaggio's dramatic realism.

A pupil of her father and of his friend, the landscape painter Agostino Tassi, she painted at first in a style indistinguishable from her father's somewhat lyrical interpretation of Caravaggio's example. Her first known work is "Susanna and the Elders" (1610), an accomplished work long attributed to her father. She was raped by Tassi, and, when he did not fulfill his promise to marry her, Orazio Gentileschi in 1612 brought him to trial. During that event she herself was forced to give evidence under torture. She married a Florentine shortly after the trial and joined the Academy of Design in Florence in 1616. While in Florence she began to develop her own distinct style. Her colours are more brilliant than her father's, and she continued to employ the tenebrism made popular by Caravaggio long after her father had abandoned that style. Although her compositions were graceful, she was perhaps the most violent of all the Caravaggisti; she illustrated such subjects as the story from the Apocrypha of Judith, the Jewish heroine, beheading Holofernes, an invading general.

Artemisia Gentileschi was in Rome for a time and also in Venice. About 1630 she moved to Naples and in 1638–39 visited her father in London. There she painted many portraits and quickly surpassed her father's fame. Later, probably in 1640 or 1641, she settled in Naples, but little is known of the final years of her life.

**BIBLIOGRAPHY.** Mary D. Garrard, *Artemisia Gentileschi: The Image of the Female Hero in Italian Baroque Art* (1989).

**Gentileschi, Orazio**, original name ORAZIO LOMI (b. 1562, Pisa [Italy]—d. c. 1639, London, Eng.). Italian Baroque painter, one of the more important painters who came under the influence of Caravaggio and who was one of the more successful interpreters of his style.

Gentileschi first studied with his half brother Aurelio Lomi. At some time in the late 1570s or early 1580s he went to Rome, where, with the landscape painter Agostino Tassi, he painted frescoes in churches of Santa Maria Maggiore, San Giovanni Laterano, and Santa Nicola in Carcere from about 1590 to 1600, executing figures for Tassi's landscapes.

In the first years of the 17th century Gentileschi came under the influence of Caravaggio, also in Rome at the time. His paintings of

"The Annunciation," painting by Orazio Gentileschi, 1623; in the Galleria Sabauda, Turin, Italy  
SCALA—Art Resource

this period (e.g., "David and Goliath," 1610?, and "St. Cecilia and the Angel," 1610?) employ Caravaggio's use of dramatic, unconventional gesture and monumental composition, his uncompromising realism and contemporary representation of figure types, and to some extent his strong chiaroscuro, or light-and-dark contrast. Shortly afterward Gentileschi developed a Tuscan lyricism foreign to Caravaggio's almost brutal vitality, a lighter palette, and a more precise treatment reminiscent of his Mannerist beginnings. From 1621 to 1623 Gentileschi was in Genoa, where he painted his masterpiece, "The Annunciation" (1623), a work of consummate grace that shows a weakening of Caravaggio's influence. The composition still depends on dramatic gestures, here of the Virgin and the angel, and there is still a strong immediacy to the incident and an absence of idealization. The mood, however, is more restrained and lyrical than in his earlier works, the colours are light, and the earlier chiaroscuro is absent.

After a stay in France, Gentileschi traveled to England in 1626 at the invitation of King Charles I; he remained there as court painter for the rest of his life, his work becoming increasingly conventional and decorative. His last major work is an ambitious series of ceiling paintings for the Queen's House, Greenwich, painted probably after 1635, and now in Marlborough House, London.

**Gentili, Alberico** (b. Jan. 14, 1552, San Ginesio, Papal States [Italy]—d. June 19, 1608, London, Eng.). Italian jurist considered by many to be the founder of the science of inter-

national law and said to have been the first in western Europe to separate secular law from Roman Catholic theology and canon law.

A graduate of the University of Perugia, Italy (doctor of civil law, 1572), Gentili was exiled from Italy in 1579 because of his Protestantism. From 1581 until his death he taught at the University of Oxford, becoming well known for his lectures on Roman law and for his numerous writings.

In 1588 Gentili published *De jure belli commentatio prima* ("First Commentary on the Law of War"), the first of a three-volume series. A complete, revised edition appeared in 1598 as *De jure belli libri tres* ("Three Books on the Law of War"). In his view, international law should comprise the actual practices of civilized nations, tempered by moral (but not specifically religious) considerations. Although he rejected the authority of the church, he used the reasoning of the canon law as well as the civil law whenever it suited his purpose. The Dutch jurist Hugo Grotius, in writing the much better known *De Jure Belli ac Pacis* (1625; *On the Law of War and Peace*), drew extensively on Gentili's work.

**Gentleman Jim** (boxer): see Corbett, James J(ohn).

**Gentleman's Magazine** (1731–1914), long-popular English periodical that gave the name "magazine" to its genre. It was the first general periodical in England, founded by Edward Cave in 1731. It originated as a storehouse, or magazine, of essays and articles culled from other publications, often from books and pamphlets. Its motto—"E pluribus unum"—took note of the numerous sources scoured to assemble one monthly issue. Dr. Samuel Johnson joined *Gentleman's Magazine* in 1738, and a short time later it began to publish parliamentary reports and original writing.

**Gentlemen's Agreement** (1907), U.S.-Japanese understanding, in which Japan agreed not to issue passports to emigrants to the United States, except to certain categories of business and professional men. In return, President Theodore Roosevelt agreed to urge the city of San Francisco to rescind an order by which children of Japanese parents were segregated from white students in the schools.

The issue reflected the prejudices of Californians who feared that Japanese immigrants (a thousand arrivals monthly) would depress wages and gain control of most of the good farming land. The Japanese government carried out faithfully its part of the agreement and the San Francisco school board repealed the segregation order, but the bias and discrimination against Japanese in California continued.

**Gentofte**, northern residential suburb of Copenhagen, Den. It maintains itself as a separate municipality (København *amtskommune* [county commune]), although it is now indistinguishable from the surrounding suburbs. It is the site of a horse-trotting course and the renowned Tuborg breweries. Most of the foreign embassies in Denmark are located in Gentofte. Pop. (1990 est.) 65,303.

**Gentry, Charter to the**, also called **CHARTER TO THE NOBILITY**, formally **CHARTER FOR THE RIGHTS, FREEDOMS, AND PRIVILEGES OF THE NOBLE RUSSIAN GENTRY**, Russian ZHALOVANNAYA GRAMOTA DVORYANSTVU ("Given Charter for the Gentry"), or GRAMOTA NA PRAVA, VOLNOSTY, Y PREIMUSHCHESTVA BLAGORODNOGO ROSSIYSKOGO DVORYANSTVA (1785), edict issued by the Russian empress Catherine II the Great that recognized the corps of nobles in each province as a legal corporate body and stated the rights and privileges bestowed upon its members. The charter accorded to the gentry of each province and county in Russia (excluding those of northern European Russia and Siberia) the right to meet every three years in a general assembly that

could discuss and take action on the nobles' local affairs, elect a marshal of the nobility, and directly petition the autocrat on matters of importance to the gentry.

The charter also confirmed the nobles' exemption from compulsory service to the state and from payment of taxes. It granted them the rights of free speech and assembly, as well as the right to a trial by their peers. Members of the gentry exclusively were allowed to own estates populated by serfs; estates owned by nobles were made hereditary property, and the power to revoke title to an estate (as well as to revoke a nobleman's rank) was entrusted to the courts. The charter gave the gentry extensive power over its serfs; the nobles gained judicial authority over all crimes committed by serfs except robbery and murder and were empowered to sentence a serf to penal servitude in Siberia and also to recall him.

The charter, however, by accentuating distinctions among certain elements of the nobility, actually fostered enmity between the old aristocracy (descendants of princes and boyars) and the new gentry (which acquired its status as reward for service to the state). Nonetheless, by its recognition of the nobility as an elite class, the charter ensured that the gentry would support and maintain the autocratic form of government in Russia.

**Gentz, Friedrich**, also called FRIEDRICH VON GENTZ (b. May 2, 1764, Breslau, Silesia, Prussia [now Wrocław, Pol.]—d. June 9, 1832, Vienna, Austria), German political journalist, famous for his writings against the principles of the French Revolution and Napoleon and as a confidential adviser of Metternich. Though a commoner, he sometimes affected the *von* of nobility, having received a Swedish knighthood in 1804.

*Early life and career.* Gentz's father was a Prussian civil servant; his mother came from the French Huguenot colony of Berlin, with which young Gentz liked to associate. Up to an advanced age, he wrote his diaries in French, displaying in that language the same limpid elegance that distinguished his German. He studied under the German philosopher Immanuel Kant in Königsberg but was essentially self-taught, acquiring historical, juridical, and economic knowledge from books, chiefly English works. In 1785 Gentz entered the Prussian civil service in Berlin and in 1793 became a secretary in the War Office.

With the outbreak of the French Revolution, Gentz began his career as a political writer. As a pupil of Immanuel Kant, he had at first hailed the Revolution as the "awakening of mankind." But he soon began to criticize the Revolution and ended by combatting it. In 1793 he published a German translation of Edmund Burke's *Reflections on the Revolution in France*; thereafter, Burke, the great English conservative, remained for Gentz the master whose ideas most closely reflected his own and whose style he admired and imitated. In two periodicals he acquired or founded anew, *Neue deutsche Monatsschrift* and *Historisches Journal*, as well as in brochures published at irregular intervals from 1800 on, Gentz continued to analyze the great drama that unfolded in France. Gentz's writings of 1795–1802 are still uncannily topical. His attitude, which would now be called that of a conservative liberal, made him advocate the preservation of civic liberties against autocratic egalitarianism, the defense of the rule of law throughout Europe against illegitimate imperialism, and the maintenance of the equilibrium of powers against the encroachments of the one universal state, which, in his view, all French governments after 1793 were bound to strive for. In particular, Gentz pointed out the differences between the American and the French revolutions, seeing in the former a defense of historical rights against British usurpation, in the latter an antihistorical, aggressive, ide-

Gentz, detail of a portrait by Sir Thomas Lawrence; in Windsor Castle, Berkshire  
Copyright reserved

ology-laden undertaking. These political investigations were complemented by economic research, as in the great essay *Über die britische Finanzverwaltung* ("On British Financial Administration").

As a politician, Gentz strove for a coalition of "Free Europe" against French despotism. But, since Prussia observed a policy of strict neutrality during the period 1795–1806, Gentz's position in Berlin became increasingly untenable. In 1803 he accordingly moved to Vienna, the centre, as he hoped, of the Continent's resistance to Napoleon. The net result of his advocacy, however, was a series of disappointments: the War of the Third Coalition (1805–07) ended with the allied defeat at the Battle of Austerlitz and a rapprochement between Russia and France, and the Fourth Coalition ended with a Franco-Austrian alliance cemented by Napoleon's marriage to a Habsburg archduchess. Gentz found himself in a state of melancholy isolation; by 1810 his advocacy of European freedom had begun to weaken.

*Association with Metternich.* Gentz's friendship with the new Austrian foreign minister, Prince von Metternich, helped him gain access to the Vienna state chancery, this time with the regular title of *Hofrat* (privy councillor). Metternich, whom he admired as a skeptical, worldly-wise man of affairs and a pragmatic politician, became his mentor; Gentz, in turn, became the all-powerful minister's propagandist and confidential adviser.

The War of Liberation that began with Napoleon's catastrophe in Russia and ended with his overthrow evoked little enthusiasm in Gentz's tired spirit. He reached the peak of success at a time when his energies had already begun to flag. Gentz was allowed to officiate as secretary general of the great congresses of the immediate post-Napoleonic era—those held at Vienna, Aachen (Aix-la-Chapelle), Troppau, Laibach, and Verona. It was a position that entailed many advantages by way of orders and decorations, influence, and money. As he had earlier formulated the Austrian and Prussian war manifestos against Napoleon, so he now wrote up, with the same untiring skill, the protocols of these European congresses. These activities were of a rigidly conservative and purely defensive nature. The idea of "European freedom" was replaced by the old order of the Continent, an idealized 18th century, which Gentz defended against the 19th.

The last chapter in Gentz's life was a personal one: his liaison, at the age of 66, with young Fanny Elssler, a ballerina. It was his final triumph and his first complete happiness, and, when it paled, he soon died. His possessions had to be auctioned off in order to satisfy the creditors. Metternich paid for the funeral.

(G.Ma./Ed.)

**BIBLIOGRAPHY.** Two biographies of Gentz are Paul R. Sweet, *Friedrich von Gentz, Defender of the Old Order* (1941, reissued 1970); and Golo Mann, *Secretary of Europe: The Life of Friedrich Gentz, Enemy of Napoleon* (1946, reissued 1970).

**genus**, plural **GENERA**, biological classification ranking between family and species, consisting of structurally or phylogenetically related species or an isolated species exhibiting unusual differentiation (monotypic genus). Thus the species of roses collectively form the genus *Rosa*, of horses and zebras, the genus *Equus*. The genus name is the first word of a binomial scientific name (the species name is the second word) and is always capitalized. Thus the tea rose is *Rosa odorata*; the common horse is *Equus caballus*. See also species.

**Gény, François** (b. Dec. 17, 1861, Baccarat, Meurthe-et-Moselle, Fr.—d. Dec. 16, 1959, Nancy), French law professor who originated the *libre recherche scientifique* ("free scientific research") movement in jurisprudence. His advocacy of this principle liberalized the interpretation of codified law in France and thus helped to increase popular confidence in the judiciary. His approach also influenced legal philosophy in other countries.

A university law teacher, Gény was appointed in 1901 professor of civil law and, in 1919, dean of the faculty of law at the University of Nancy; this office he occupied until 1925. In 1930 he became corresponding member of the Academy of Moral and Political Sciences.

Gény emphasized the element of judicial discretion in making law. He attacked the traditional assumption underlying the interpretation of the Napoleonic Code (French civil code)—that the code had solved all legal problems, even those that could not have been foreseen. In his view, courts are free to make their own rules when preexisting written or unwritten law fails to cover the situation. According to his philosophy, the law results from applying juristic techniques, or "constructions" (*construits*), to the given data (*donnés*) of the social sciences.

**Geo-zoo** (Munich, Ger.): see Hellabrunn Zoo.

**geocentric system**, any theory of the structure of the solar system (or the universe) in which Earth is assumed to be at the centre of all. The most highly developed geocentric system was that of Ptolemy of Alexandria (2nd century AD). It was generally accepted until the 16th century, after which it was superseded by heliocentric models such as that of Nicolaus Copernicus. Compare heliocentric system; Ptolemaic system; Tychonic system.

**geochemical cycle**, developmental path followed by individual elements or groups of elements in the crustal and subcrustal zones of the Earth and on its surface. The concept of a geochemical cycle encompasses geochemical differentiation (*i.e.*, the natural separation and concentration of elements by Earth processes) and heat-assisted, elemental recombination processes.

For the lithosphere (*i.e.*, the crust and upper mantle), the geochemical cycle begins with the crystallization of a magma at the surface or at depth. In turn, surface alteration and weathering break down the igneous rock, a process that is followed by the transportation and deposition of the resulting material as sediment. This sediment becomes lithified and eventually metamorphosed until melting occurs and new magma is generated. This ideal cycle can be interrupted at any point. Each element may be affected differently as the cycle progresses. During the weathering of an igneous rock, for example, minerals containing iron, magnesium, and calcium break down and are carried in solution, but silicon-rich quartz and

feldspar are mainly transported as sediment. The resultant sedimentary rocks are dominated by quartz and feldspar, whereas others are dominated by calcium and magnesium owing to the precipitation of calcium or magnesium carbonates. Such elements as sodium remain in solution until precipitated under extreme conditions. As partial melting of sedimentary rocks begins, elements become separated according to melting properties; volatiles are released to the atmosphere, and physical movement of chemically separated bodies occurs. While the geochemical cycle over a short term is in a seemingly steady state, long-term, or secular, changes occur. Thus, for example, continents and oceans have evolved over geologic time.

**geochemistry**, scientific discipline that deals with the relative abundance, distribution, and migration of the Earth's chemical elements and their isotopes.

A brief treatment of geochemistry follows. For full treatment, see *MACROPAEDIA*: Earth Sciences.

Until the early 1940s geochemistry was primarily concerned with defining elemental abundances in minerals and rocks. Since that time, investigators have broadened the scope of their research significantly, studying, for example, the continual recycling of the Earth's constituent materials through agencies of the hydrosphere and atmosphere coupled with seafoam spreading, mountain building, and other processes involving the terrestrial crust. Modern geochemical research also includes the study of chemical transformations of biological materials in rocks and the cyclic flow of individual elements (and their compounds) between living and nonliving systems. Since the 1960s, certain areas of geochemical research have become interlinked with cosmology—*e.g.*, the study of the origin and relative abundance of elements in the solar system, the Milky Way Galaxy, and the universe as a whole; the chemical composition of meteorites; and the ages of terrestrial and lunar rocks.

**geochronology**, scientific study concerned with the sequence of geologic events in the history of the Earth.

A brief treatment of geochronology follows. For full treatment, see *MACROPAEDIA*: Geochronology.

Geologic history provides a conceptual framework and overview of the evolution of the Earth. An early development of the subject (initiated in the early 1800s) was stratigraphy, the systematic study of order and sequence, including faunal succession, in bedded sedimentary rocks. Applying the general principle of stratigraphy that different sedimentary strata contain different and distinctive fossils, investigators of the 19th and early 20th centuries were able to correlate strata with similar fossils over large areas. More recently, specialists in biostratigraphy have employed fossil remains to characterize successive intervals of geologic time, but only as relatively precise time markers to about 570 million years ago. Since the mid-20th century, radiometric dating has provided absolute age data to supplement the relative dates obtained from the fossil record and made it possible to quantify the geologic time scale as far back as the oldest rocks more than 3.9 billion years ago. Radiometric-dating techniques are based on the principle that radioactive isotopes in geologic material decay at constant, known rates to daughter isotopes. Using such techniques, investigators have been able to calculate the ages for various rock-forming minerals and thereby date the rocks and strata that contain such minerals. These dates have furnished an absolute age framework for the stratigraphic time scale

that had been developed by matching the evolutionary changes exhibited by fossil remains in successive rock beds.

**geode**, hollow mineral body found in limestones and some shales. The common form is a slightly flattened globe ranging in diameter from 2.5 to more than 30 cm (1 to 12 inches) and containing a chalcedony layer surrounding an inner lining of crystals. The hollow interior often is nearly filled with inward-projecting crystals, new layers growing on top of old. The crystals are of quartz, less often of calcite or dolomite, and sometimes of aragonite, ankerite, hematite, magnetite, pyrite, chalcocopyrite, and sphalerite. Most often the metal sulfides are innermost, and a layer of calcite is next to the outer chalcedonic layer; a second layer of chalcedony sometimes is present.

Geodes form by expansion from an initial fluid-filled cavity, such as the opening in a bivalve. The initial deposit, chalcedony, forms from a silica gel that surrounds and isolates the salt solution. If the water surrounding the forming geode becomes less saline, osmosis begins to bring the salinity inside into equilibrium with that outside (water seeps in, diluting the trapped solution), and the internal pressure increases. The geode will expand in response to the pressure, either at the expense of the surrounding limestone, which dissolves at the limestone-silica interface, or, if the limestone has not hardened, by pushing aside the lime mud. Expansion continues until the pressure difference becomes negligible. If the initial cavity is inside a fossil, the fossil is burst by the expanding geode. Ultimately, dehydration and crystallization of the silica gel occur, followed by shrinkage, cracking, and the entrance of water carrying dissolved minerals, which are deposited on the chalcedony wall.

**geodesic dome**, spherical form in which lightweight triangular or polygonal facets consisting of either skeletal struts or flat planes, largely in tension, replace the arch principle and distribute stresses within the structure itself. It was developed in the 20th century by R. Buckminster Fuller of the United States.

Geodesic dome construction by R. Buckminster Fuller, 20th century

A geodesic dome may be supported by light walls, but unlike other large domes it can also be set directly on the ground as a complete structure. A large geodesic dome was used to house the United States exhibit at Expo 67 in Montreal in 1967. Among many design applications are sports arenas, theatres, greenhouses, and exhibition halls.

**geodesy**, scientific discipline concerned with the precise figure of the Earth and its determination and significance. Until the advent of satellites, all geodesic work was based on land surveys made by triangulation methods employing a geodesic coordinate system (one used to study the geometry of curved surfaces). It is now possible to use satellites in conjunction with the land-based system to refine knowledge of the Earth's shape and dimensions; this endeavour is sometimes termed satellite geodesy.

**geoduck** (species *Panopea generosa*), marine invertebrate of the class Bivalvia (phylum Mollusca) that inhabits the sandy muds of the intertidal and shallow sublittoral zones of the Pacific coast of North America from southern Alaska to Baja California. The geoduck is the largest known burrowing bivalve. Its gaping shell reaches about 180–230 mm (7–9 inches) in length, but the siphons, which cannot be retracted into the shell, may extend up to 1.3 m (about 4 feet). The clam, including the shell, may weigh as much as 3.6 kg (8 pounds). The geoduck is highly prized for food, but inhabits deep burrows and is difficult to dig out. The name is probably derived from a Nisqually Indian phrase meaning “dig deep.” Several species similar to the Pacific geoduck occur in other parts of the world. *Panopea bitruncata*, for example, is found from the coast of North Carolina to the Gulf of Mexico.

**Geoffrey** (personal name): see under Godfrey, except as below.

**Geoffrey**, French GEOFFROI, or GEOFFROY, name of rulers grouped below by country and indicated by the symbol ●.

ANJOU

● **Geoffrey II**, byname GEOFFREY MARTEL, French GEOFFROI MARTEL (b. Oct. 14, 1006—d. Nov. 14, 1060, Angers, Anjou [France]), count of Anjou (1040–60), whose territorial ambitions, though making him troublesome to his father, Fulk III Nerra, resulted in the further expansion of Angevin lands after his father's death. (Geoffrey's byname, Martel, means “the Hammer.”)

In 1032 Geoffrey married Agnes, widow of William V the Great, Duke of Aquitaine. Claiming Aquitaine for Agnes' children by William the Great, Geoffrey attacked William's son by an earlier marriage, William the Fat, who had succeeded his father as duke. Fulk, who was William's vassal, sided with him against Geoffrey. Geoffrey in turn tried to seize his father's lands while the latter was on a pilgrimage to the Holy Land (1039); Fulk pardoned him only after forcing him to suffer great humiliation.

When Fulk died in 1040, Geoffrey embarked on a policy of expansion that at various times during the next 20 years brought him into conflict with Thibaut III, Count of Blois and Champagne; Henry I, king of France; and William I, Duke of Normandy; he extended his lands to include Touraine and a large part of Maine.

● **Geoffrey IV**, also called GEOFFREY PLANTAGENET, byname GEOFFREY THE FAIR, French GEOFFROI PLANTAGENET, or GEOFFROI LE BEL (b. Aug. 24, 1113—d. Sept. 7, 1151, Le Mans, Maine [France]), count of Anjou (1131–51), Maine, and Touraine and ancestor of the Plantagenet kings of England through his marriage, in June 1128, to Matilda (*q.v.*), daughter of Henry I of England. On Henry's death (1135), Geoffrey claimed the duchy of Normandy; he finally conquered it in 1144 and ruled there as duke until he gave it to his son Henry (later King Henry II of England) in 1150.

Geoffrey was popular with the Normans, but he had to suppress a rebellion of malcontent Angevin nobles. After a short war with Louis VII of France, Geoffrey signed a treaty (August 1151) by which he surrendered the whole of Norman Vexin (the border area between Normandy and Ile-de-France) to Louis.

BRITTANY

● **Geoffrey IV**, also called GEOFFREY PLANTAGENET, French GEOFFROI PLANTAGENET (b. Sept. 23, 1158—d. Aug. 19?, 1186, Paris [France]), duke of Brittany and earl of Richmond, the fourth, but third surviving, son of Henry II of England and Eleanor of Aquitaine. In 1166, in furtherance of his father's policy

of extending and consolidating Angevin power in France, Geoffrey was betrothed to Constance, daughter and heir of Conan IV, Duke of Brittany. At the same time, Duke Conan was forced to surrender to Henry II for Geoffrey's use the whole duchy of Brittany except the county of Guingamp. Geoffrey received the homage of the Breton nobles in 1169, and in 1173 he joined the rebellion against Henry II led by his eldest brother, Henry, the "Young King," and supported by the rulers of France, Scotland, and Flanders. He submitted to his father at Michaelmas, 1174, and was sent back to Brittany, where he proceeded to recover lost ducal estates and subdue rebellious barons. He and Constance were married in 1181.

From then until his death he fought against both his brother Richard the Lion-Heart and his father (toward whom he behaved atrociously), largely for possession of Anjou. In 1185 he issued an "assize" at Rennes regularizing the succession to military fiefs in Brittany. He died at Paris, either of illness or in a tournament, leaving a daughter, Eleanor, and a posthumous son, Arthur I.

#### NORMANDY

• **Geoffrey:** see Geoffrey IV (Anjou).

**Geoffrey OF MONMOUTH** (d. 1155), medieval English chronicler and bishop of St. Asaph (1152), whose major work, the *Historia regum Britanniae* (*History of the Kings of Britain*), brought the figure of Arthur into European literature.

In three passages of the *Historia* Geoffrey describes himself as "Galfridus Monemutensis," an indication that he probably came from Monmouth. Possibly of Breton descent, he appeared as witness to a number of documents in Oxford during the period 1129–51. Geoffrey alleges that the *Historia* was translated from a "very old book in the British tongue" brought by Walter, archdeacon of Oxford, from Brittany. This seems a pure fabrication, but it is clear that Geoffrey was for most of his life an Oxford cleric, closely connected with Walter and sharing with him a taste for letters. He may have been an Augustinian canon in the secular college of St. George, Oxford, of which Walter was provost.

The *Historia regum Britanniae*, published sometime between 1135 and 1139, was one of the most popular books of the Middle Ages, although its historical value is almost nil. The story begins with the settlement of Britain by Brutus the Trojan, great-grandson of Aeneas, and by the Trojan Corineus, the eponymous founder of Cornwall, who exterminate giants inhabiting Britain. Then follow the reigns of the early kings down to the Roman conquest; here are found such well-known episodes as those of Loqrine and Sabrina, the founding of Bath by Bladud and of Leicester by Leir (Lear), and the division of Leir's kingdom between the two ungrateful daughters. The story of the Saxon infiltration during the reign of the wicked usurper Vortigern, of the successful resistance of the Saxons by Vortimer, and of the restoration of the rightful line, followed by the great reigns of Aurelius and his brother Uther Pendragon, leads up to the account of Arthur's conquests, the culminating point of the work. Chapters 106–111 introduce the enchanter Merlin, who predicts, in an obscure and apocalyptic manner, the future political history of Britain. These chapters were first published separately, before 1136, and dedicated to Alexander, bishop of Lincoln. They gave rise to the genre of political prophecies attributed to Merlin. Probably between 1148 and 1151, Geoffrey produced a poem in ornate Latin hexameters, the *Vita Merlini*, which portrays a Merlin whose adventures are based on genuine Celtic material about a madman with a gift for divination.

Denounced from the first by sober historians,

Geoffrey's fictional history nevertheless had an enormous influence on later chroniclers. Romanticized versions in the vernacular, the so-called *Bruts*, were in circulation from about 1150. Writers of the later Middle Ages gave the material a wide currency; and indeed Geoffrey's influence was at its greatest after the accession of the Tudors. The text, with an English translation, was published in 1929 by Acton Griscom and Robert Ellis Jones. J.J. Parry produced an edition of the *Vita Merlini* in 1925.

**Geoffrey OF VILLEHARDOUIN**, French GEOFFROI DE VILLEHARDOUIN: see Villehardouin, Geoffrey of.

**Geoffrin, Marie-Thérèse Rodet** (b. 1699, Paris, Fr.—d. 1777, Paris), French hostess whose salon in the Hôtel de Rambouillet was an international meeting place of artists and men of letters from 1749 to 1777.

The daughter of a valet, she married a rich manufacturer, a member of the newly influential bourgeoisie, with whom she had no rapport. Although lacking formal education herself, Madame Geoffrin was sensitive, an excellent listener, and naturally intelligent; she inherited the salon of the more unconventional Madame de Tencin, gave it an added tone of respectability, and became a generous, motherly patron to her guests and protégés, offering them criticism and advice. She ruled her domain with tact and strictness; neither religion nor politics as a subject of conversation was permitted. On Mondays such artists as François Boucher, Maurice-Quentin de La Tour, and Jean-Baptiste Greuze attended; on Wednesdays writers, including Horace Walpole, Pierre Marivaux, Bernard de Fontenelle, and Helvétius were present. Madame Geoffrin's salon was also a centre for the Encyclopédistes, whose vast project she subsidized.

**Geoffroy**, also spelled GEOFFROI (French personal name): see under Geoffrey, except as below.

**Geoffroy, Étienne-François**, also called GEOFFROY L'AÎNÉ, or GEOFFROY THE ELDER (b. Feb. 13, 1672, Paris, Fr.—d. Jan. 6, 1731, Paris), French chemist, the first chemist to speak of affinity in terms of fixed attractions between different bodies.

Étienne-François Geoffroy, engraving by Landon after a portrait by Nicolas de Largillière  
H. Roger-Viollet

Assuming that one acid displaces another acid of weaker affinity for a specific base in the salt of that base, Geoffroy composed tables (1718) listing the relative affinities of different reagents for particular substances. Geoffroy's tables remained an authoritative reference throughout most of the 18th century, until they were invalidated by Claude-Louis Berthollet's demonstration that the thoroughness of chemical reactions depends upon the relative quantities of the starting materials and the physical conditions pertaining during the reaction.

Geoffroy was professor of chemistry at the

Jardin du Roi, Paris, and of pharmacy and medicine at the Collège de France, Paris (1712–31). He considered the quest for the philosopher's stone (a substance capable of transforming base metals into gold) a delusion, but he believed that iron could be formed during the combustion of vegetable matter. His works included *Tractatus de Materia Medica* (1699; "Treatise on Pharmacology").

**Geoffroy Saint-Hilaire, Étienne** (b. April 15, 1772, Étampes, Fr.—d. June 19, 1844, Paris), French naturalist who established the principle of "unity of composition," postulating a single consistent structural plan basic to all animals as a major tenet of comparative anatomy, and who founded teratology, the study of animal malformation.

After taking a law degree (1790), Geoffroy studied medicine under Louis Daubenton and enrolled in science courses at the Collège du Cardinal Lemoine in Paris. At the height of the Revolution in 1792, he risked his life to save several of his teachers and fellows from execution. The following year, Daubenton arranged his appointment as superintendent of the cabinet of zoology at the Jardin des Plantes, and, when the gardens were converted to the National Museum of Natural History, Daubenton obtained for him one of its chairs of zoology.

In 1794, when the agronomist Alexandre-Henri Tessier wrote enthusiastically to the faculty about his young protégé, Georges Cuvier, Geoffroy immediately invited Cuvier to work with him, and the two began a collaboration that resulted in their joint publication of five works, one of which proposed a "subordination of characters"—a method for distinguishing only those animal features that allowed them to be separated into phyla; this became a basic principle of Cuvier's zoological system.

In 1798 Geoffroy was appointed a member of the scientific expedition accompanying Napoleon's invasion of Egypt. Three years later he succeeded, against the wishes of the British, in transporting the specimens collected there back to France. Following his election to the Academy of Sciences (1807), he was again called upon by Napoleon, this time to obtain the collections of Portuguese museums by any means. Exercising tact, he obtained the specimens by exchanging items from French museums.

After his appointment as professor of zoology at the University of Paris (1809), he began the anatomical studies that he would later summarize in *Philosophie anatomique*, 2 vol. (1818–22). His studies on embryos supplied important evidence for his views on the unity of organic composition among vertebrates, which he now defined in three parts: the law of development, whereby no organ arises or disappears suddenly, explaining vestiges; the law of compensation, stipulating that one organ can grow disproportionately only at the expense of another; and the law of relative position, stating that the parts of all animals maintain the same positions relative to each other.

When Geoffroy attempted to apply this philosophy to invertebrates in 1830, a major dispute arose with Cuvier, who had independently separated all animals into four immutable groups. The debate that followed divided the scientific world and compelled both men to elaborate their models of natural history. While Geoffroy believed that ancestral species historically gave rise to unchanging modern forms through the occasional evolutionary appearance of successful monstrosities, Cuvier denied evolution entirely. Geoffroy's evolutionary concepts did much to create a receptive scientific audience for Charles Darwin's arguments.

**Geoffroy Saint-Hilaire, Isidore** (b. Dec. 16, 1805, Paris, Fr.—d. Nov. 10, 1861, Paris), French zoologist noted for his work on anatomical abnormalities in humans and lower animals.

In 1824 Geoffroy joined his father at the National Museum of Natural History as an assistant naturalist, and, after taking his M.D. in 1829, he taught zoology from 1830 to 1833. He was elected a member of the Academy of Sciences in Paris in the latter year. In his *Histoire générale et particulière des anomalies de l'organisation chez l'homme et les animaux*, 4 vol. (1832–37; “General and Particular History of Structural Monstrosities in Man and Animals”), he introduced the term teratology for the study of congenital abnormalities.

Geoffroy succeeded his father in 1837 in Paris as professor of comparative anatomy at the Faculty of Sciences and, in 1841, at the National Museum of Natural History. He organized the Faculty of Sciences at Bordeaux in 1838 and served as inspector general of the University of Paris in 1844 and as a member of the royal council for public instruction the same year. In 1854 he founded the Société d'Acclimatation to study how animals adjust to different climates and in 1856 was elected president of the Academy of Sciences in Paris. In 1847 he published a scientific biography of his father, *Vie, travaux, et doctrine scientifique d'Étienne Geoffroy Saint-Hilaire* (“Life, Works, and Scientific Principles of Étienne Geoffroy Saint-Hilaire”).

**Geoffroy's cat** (species *Oncifelis geoffroyi*), South American cat, family Felidae, found in mountainous regions, especially in Argentina. It is gray or brown with black markings and grows to a length of about 90 cm (36 inches), including a tail of about 40 cm (16 inches). Geoffroy's cat climbs well and preys on small mammals and birds. It breeds once a year; litters consist of two or three kittens.

**geographic cycle:** see geomorphic cycle.

**geographic information system:** see GIS.

**Geographic Names, Board on (BGN)**, interdepartmental agency of the U.S. government created in 1890 and providing standardized geographic names of foreign and domestic places for use by the federal government. It was established in its present form by a public law enacted in 1947. Located in Washington, D.C., the BGN shares its responsibilities with the Department of the Interior and operates through several committees composed of members of various federal departments and agencies. The BGN publishes a series of gazetteers of foreign countries based on the work of geographers, linguists, and cartographers; gazetteers of Antarctica, undersea features, and most countries except the United States had been published by the early 1980s. Responsibility for producing and distributing the gazetteers lies with the Defense Mapping Agency, Department of the Interior. In the late 1990s a portion of the information gathered by the BGN was made available on the Internet.

**Géographie Universelle**, major French work on the regional geography of the entire world. It consists of 15 volumes in 23 parts. The work is noted for its vivid characterization and description of each region.

The first French attempt to provide a universal geography was Conrad Malte-Brun's six-volume *Précis de la Géographie Universelle*, published between 1810 and 1829. A second geography, the profusely illustrated *Nouvelle Géographie Universelle* by Elisée Réclus (*q.v.*), comprised 19 volumes that were published between 1876 and 1894. Réclus's effort was

largely successful and has been called the “greatest individual writing feat in the history of geography.” A third, expanded version was published as *Géographie Universelle*. It was organized and initiated by the French geographer Paul Vidal de la Blache (*q.v.*) but represented the combined efforts of some 15 geographers, mostly his students, under the editorship of Lucien Gallois. The set was published over a 19-year period (1927–46).

**geography** (from Greek *gēo*, “earth,” *graphein*, “to write”), the scientific study of the Earth's surface. Geography describes and analyzes the spatial variations in physical, biological, and human phenomena that occur on the surface of the globe and treats their interrelationships and their significant regional patterns.

A brief treatment of the discipline of geography follows. For full treatment, see MACROPAEDIA: Geography. Related subjects are treated in a number of articles in the MACROPAEDIA. For historical and technical treatment, see Earth Sciences; European Overseas Exploration and Empires, The History of; Mapping and Surveying.

For a description of the place of geography in the circle of learning, see PROPAEDIA: Part Ten, Division III.

Geography is one of the oldest subjects of study, and it has been called the mother of sciences. In the classical world geography had close ties with history (as in Herodotus) in attempting to describe what other lands and peoples were like or with astronomy and philosophy (as in Eratosthenes and Ptolemy) in trying to ascertain the size of the Earth and to locate places on it. Alexander von Humboldt (1769–1859), a German naturalist and geographer, was a key figure in the rise of modern geography because of his exact measurements, his careful recording of observations, and his mapping of significant areal patterns of human and natural features.

Though once associated entirely with mapping and the exploration of the Earth, the discipline of geography is today a wide-ranging one. Any pattern of spatial variation of phenomena on the surface of the Earth may be influenced by many of the processes that animate the natural and human realms, requiring geographers to be conversant with the principles of the biological, social, and earth sciences. Desertification in Africa, for example, is often attributed to drought, but studies reveal that it has been accelerated by overgrazing, overexpansion of farming, and removal of trees and shrubs for firewood. Many such phenomena are studied by other specialists, but it is the distinctive task of the geographer to investigate their distributional patterns, their regional complexes, the networks that link the elements, and the processes involved in the interaction among them.

The special subdisciplines of geography are divided into areas of physical, human, and regional geography. Physical geography is further subdivided into geomorphology, climatology, biogeography, and hydrology. In this category particular attention has been paid to coastal areas, to water and mineral resources (including energy), and to natural hazards. Human geography includes historical geography, cultural and social geography, population geography, political geography, economic geography (including the study of agriculture, industry, trade, and transportation), and urban geography. Medical geography, environmental management, and conservation of resources fall between these two large fields. The scale of study in regional geography may range from worldwide regionalization, to a continent, a major cultural area, a country, a subregion within a country, or a city.

Geography utilizes a battery of methods and techniques. Particularly important are direct

field observations and mapping. Methods of observation have been enhanced by such means as aerial photography and electronic remote sensing from artificial Earth satellites. Statistical methods help in spatial analysis of quantitative data, particularly census and survey data. Maps, however, remain the distinctive tool for the geographer.

The discipline of geography has many uses. It enables individuals to know the basic features of the world in which they live, the great variety of lands and peoples, the complex associations and interrelations of human beings with resources and nature, and the problems faced by inhabitants of other countries and regions. Geographic research provides explanations of the distribution of physical, biological, and human features on Earth and of their complex chains of interconnection. Applied geographic analysis has proved useful in managing resources, in understanding problems of the environment, in analyzing natural hazards (such as droughts or floods), and in measuring the distribution of environmental pollution or contamination by discharges of urban, agricultural, and industrial wastes. The analysis of unanticipated environmental effects caused by the construction of large dams and reservoirs has been particularly important. Geographers are engaged in planning land use and housing. They are an important resource in national and international agencies that deal with the study, inventory, development, or administration of natural or human resources.

**geoid**, model of the figure of the Earth that coincides with mean sea level over the oceans and continues in continental areas as an imaginary sea-level surface defined by spirit level. It is everywhere perpendicular to the pull of gravity and approximates the shape of a regular oblate spheroid. It is irregular, however, because of local buried-mass concentrations (departures from lateral homogeneity at depth) and because of differences in elevation between continents and seafloors. Mathematically speaking, the geoid is an equipotential surface: that is, it is characterized by the fact that over its entire extent the potential function is constant. This potential function describes the combined effects of the gravitational attraction of the Earth's mass and the centrifugal repulsion caused by the rotation of the Earth about its axis.

**geologic oceanography:** see marine geology.

**geologic time**, the extensive interval of time occupied by the Earth's geologic history. It extends from about 3.9 billion years ago (corresponding to the age of the oldest known rocks) to the present day. It is, in effect, that segment of Earth history that is represented by and recorded in rock strata.

The geologic time scale is the “calendar” for events in Earth history. It subdivides all time since the end of the Earth's formative period as a planet (nearly 4 billion years ago) into named units of abstract time: the latter, in descending order of duration, are eons, eras, periods, and epochs. The enumeration of these geologic time units is based on stratigraphy, which is the correlation and classification of rock strata. The fossil forms that occur in these rocks provide the chief means of establishing a geologic time scale. Because living things have undergone evolutionary changes over geologic time, particular kinds of organisms are characteristic of particular parts of the geologic record. By correlating the strata in which certain types of fossils are found, the geologic history of various regions (and of the Earth as a whole) can be reconstructed. The relative geologic time scale developed from the fossil record has been numerically quantified by means of absolute dates obtained with radiometric dating methods. The eons, eras, periods, and epochs of the geologic time scale

Geologic time						
eon	era	period	epoch (and sub-epoch)*	approximate number of years ago (in millions)

are shown in the Table. See also geochronology.

**geology**, scientific study of the Earth, including its composition, structure, physical properties, and history. The term geology is broadly inclusive and is often regarded as embracing all of the geologic sciences.

A brief treatment of geology follows. For full treatment, see MACROPAEDIA: Earth Sciences.

Geology is commonly divided into a number of subdisciplines: (1) those concerned with the chemical makeup of the solid Earth, which include the study of minerals (mineralogy) and rocks (petrology); (2) those having to do with the structure of the solid Earth, as, for exam-

ple, the study of the relationships of rocks and geologic features in general (structural geology) and the science of volcanic phenomena (volcanology); (3) those concerned with landforms and the processes that produce them (geomorphology and glacial geology); (4) those dealing with geologic history, including the study of fossils and the fossil record (paleontology), the development of sedimentary strata (stratigraphy), and the evolution of planetary bodies and their satellites (astrogeology); and (5) economic geology and its various branches—e.g., mining geology and petroleum geology. Some major fields closely allied to geology are geodesy, geophysics, and geochemistry.

The various subdisciplines of geology not only intergrade with one another but also with other branches of the Earth sciences and with such fields as physics, chemistry, biology, and mathematics. Paleontology, for instance, at times requires the use of organic chemistry, physical chemistry, and statistics. The statistical analysis of data also is an important facet of geomorphology and stratigraphy, as is the use of mathematical models.

Besides providing a better understanding of the Earth's evolution and its present features, geology serves society in a variety of practical ways. Exploration for deposits of commercially valuable minerals is broadly guided by geologic principles and conducted with geophysical and geochemical methods. The search for fossil fuels (coal, oil, and natural gas) is strongly influenced by those aspects of geology dealing with the deposition and deformation of sedimentary rocks and with the flow of underground fluids. Significant, too, is the contribution of seismological research, whose findings have enabled engineers to design structures that are better able to withstand earthquakes.

**geology, marine:** see marine geology.

**geology, structural:** see structural geology.

**geomagnetic field**, magnetic field associated with the Earth. It primarily is dipolar (i.e., it has two poles, these being the north and south magnetic poles) on the Earth's surface. Away from the surface, the dipole becomes distorted.

In the 1830s, the German mathematician and astronomer Carl Friedrich Gauss studied the Earth's magnetic field and concluded that the principal dipolar component had its origin inside the Earth instead of outside. He demonstrated that the dipolar component was a decreasing function inversely proportional to the square of the Earth's radius, a conclusion that led scientists to speculate on the origin of the Earth's magnetic field in terms of ferromagnetism (as in a gigantic bar magnet), various rotation theories, and various dynamo theories. Ferromagnetism and rotation theories generally are discredited—ferromagnetism because the Curie point (the temperature at which ferromagnetism is destroyed) is reached only 20 or so km (about 12 miles) beneath the surface, and rotation theories because apparently no fundamental relation exists between mass in motion and an associated magnetic field.

Most geomagneticians concern themselves with various dynamo theories, whereby a source of energy in the core of the Earth causes a self-sustaining magnetic field. In the dynamo mechanism, fluid motion at the Earth's core involves the movement of conducting material across an existing magnetic field, thus creating a current. The geomagnetic dynamo is by far the most important source, for without the field that it creates, other sources could not exist.

Other sources of the geomagnetic field include crustal magnetization (which occurs when the solid materials that form the Earth's crust become magnetized by the Earth's main field and cause detectable anomalies); ionospheric dynamo (the flow of charged particles across magnetic field lines that is caused by the Sun's heating of the ionosphere); the ring current (the current produced by the drift of charged particles far above the Earth's surface); magnetopause current (the sheetlike flow of particles that form a boundary between the Earth's magnetic fields and solar wind); tail current (similar to magnetopause current); field-aligned currents (caused by the circulation of magnetic field lines); and auroral electrojets (broad sheets of electric current

that flow in the northern and southern auroral ovals).

**geomagnetic reversal**, an alternation of the Earth's magnetic polarity in geologic time. *See* polar wandering.

**geomagnetics**, branch of geophysics concerned with all aspects of the Earth's magnetic field, including its origin, variation through time, and manifestations in the form of magnetic poles, the remanent magnetization of rocks, and local or regional magnetic anomalies. The latter reflect the difference between theoretical and observed magnetic intensities at points of measurement with a magnetometer, and, when plotted on a magnetic map (called an aeromagnetic map if the magnetometer was flown across the area), the anomalies provide the basis for inferences about probable subsurface structure and composition.

**Geometres, John**, also called JOHN KYRIOTES (fl. 10th century), Byzantine poet, official, and bishop, known for his short poems in classical metre. Geometres held the post of *protospatharios* (commander of the guards) at the Byzantine court and later was ordained priest, finally becoming metropolitan of Melitene in eastern Asia Minor. His poems, on both contemporary politics and religious subjects, are distinguished by considerable charm and appreciation of natural beauty. His prose works, most of which remained unpublished, include a life of the Virgin Mary, consisting of sermons for her feast days, and an encomium of Eve's apple.

**Geometric style**, style of ancient Greek art, primarily of vase painting, that began about 900 BC and represents the last purely Mycenaean-Greek art form that originated before the influx of foreign inspiration by about 800 BC. Athens was its centre, and the growing moneyed population of new Greek cities was its market.

Vases decorated in Geometric style exhibit painted horizontal bands filled with patterns, much like the vases of the preceding Proto-Geometric style. Geometric-style bands, how-

regularly spaced horizontal bands filled with sharply angular patterns in dark paint upon light ground is one of undulating rhythm, closely akin to basketry.

In addition to using abstract motifs, artists working in the Geometric style began using figures of humans and animals, seeing both as the sum of geometrized parts—bodies becoming triangles, legs and arms becoming line segments. First used just as patterns, they later developed into more complex groupings, usually narrative—funeral scenes, sea battles, dances, boxing matches, and exploits of popular heroes.

Representative objects of this period include vases, small bronze and clay figurines, elaborately decorated safety-pin-like clasps, or fibulae, and limestone seals. Artisans also made gold bands impressed with animal and human figures, which were put on the head of a deceased person, often in a way that would keep the mouth closed. Although the Geometric style gave way to the Classical style, its patterns remained popular and influenced much later Grecian art.

**geometrid moth**, any member of the large, cosmopolitan moth family Geometridae (order Lepidoptera), which includes the species commonly known as pug, wave, emerald, and carpet moths. The larvae of geometrid moths are called by a variety of common names—inchworm, cankerworm, looper, and measuring worm—and the moths themselves are sometimes called measuring worm moths.

Adult geometrids have slender bodies and broad wings. Many species resemble dried, dead leaves, but there are some brightly coloured types, especially in the tropics. When preparing to land they tend to select a background coloration into which they blend.

The distinctive coloration patterns of certain species warn predators of their foul taste. Some species have wingless females (e.g., the European winter moth *Operophtera brumata*).

Research using the currant or magpie moth (*Abraxas grossulariata*) led to the discovery of sex-linked characters (i.e., genetic characters determined by genes on the sex chromosomes). Dark forms of the peppered moth (*Biston betularia*) are used in studying industrial melanism.

**geometry**, branch of mathematics that deals with the properties of space and objects in space. It is one of the oldest branches of mathematics, having arisen in response to such practical problems as those found in surveying, and its name is derived from Greek words meaning "Earth measurement." Eventually it was realized that geometry need not be limited to the study of flat surfaces (plane geometry) and rigid three-dimensional objects (solid geometry) but that even the most abstract thoughts and images might be represented and developed in geometric terms.

A brief treatment of geometry follows. For full treatment, *see* MACROPAEDIA: Geometry; Mathematics, The History of.

In several ancient cultures, there developed a form of geometry suited to the relationships between lengths, areas, and volumes of physical objects. This geometry was codified in Euclid's *Elements* in about 300 BC on the basis of 10 axioms and postulates, from which several hundred theorems were proved by deductive logic. The *Elements* epitomized the axiomatic-deductive method for many centuries.

Analytic geometry, in which algebraic notation and procedures are used for the description of geometric objects, was introduced by René Descartes in 1637. Soon thereafter, Isaac Newton, Leonhard Euler, and others extended this idea to the study and classification of conic sections and other families of plane curves and the solution of problems involving them. These studies founded algebraic geometry, which reached its full development at the hands of Max Noether of Germany late in the

19th century and Corrado Segre and Federigo Enriques of Italy early in the 20th.

In the late 18th century, Gaspard Monge of France elaborated analytic geometry into descriptive geometry, a rational system for depicting three-dimensional objects such as buildings and machines by means of coordinated views from three perpendicular directions. The related problem of perspective in painting became the basis of a further extension, namely, projective geometry. This branch of mathematics, systematized by Victor Poncelet of France by 1822, deals with those properties of geometric figures that are not altered by projection. It provided the proper context for two celebrated theorems that had been proved by Girard Desargues and Blaise Pascal in about 1640.

The application of the concepts of mathematical analysis—continuity and limit—to the study of geometry was undertaken in about 1820 by Carl Friedrich Gauss in connection with practical problems of surveying and geodesy. Gauss initiated the field of differential geometry by providing analytic expressions for the length of arc and the curvature of plane curves and extending his results to the curvature of surfaces. From 1854 onward, his student Bernhard Riemann generalized these ideas to spaces of any number of dimensions; the resulting geometric concepts were adopted by Albert Einstein in the 20th century in framing his general theory of relativity.

Riemann's researches made him one of the principal founders of non-Euclidean geometry. Around 1830 Nikolay Lobachevsky and János Bolyai had published the results of their independent investigations of the consequences of replacing Euclid's parallel postulate with the stipulation that through a given point not on a given line, two parallels to the line can be drawn. (Gauss had examined this possibility but published nothing on it.) Riemann offered another alternative: there is no parallel. After 1870 non-Euclidean geometry was further generalized and unified with projective geometry by Felix Klein of Germany and Sophus Lie of Norway.

Topology, the youngest and most sophisticated branch of geometry, focuses on the properties of geometric objects that remain unchanged upon deformation: a doughnut and a teacup are topologically equivalent. The continuous development of topology dates from 1911, when the Dutch mathematician L.E.J. Brouwer introduced methods generally applicable to the topic.

**geōmoroi**, also called AGROIKOI, or GEORGOI, class of citizens in ancient Greek society. In 7th-century-BC Attic society, *geōmoroi* were freemen, generally peasant farm holders, lower on the social and political scale than the eupatridae, the aristocracy, but above the *dēmiourgoi*, the artisans. The *geōmoroi* were ineligible for any major political or religious post but had the right to attend sessions of the Assembly. In 580 BC, three *geōmoroi* shared the archonship (magistracy) with five eupatridae and two *dēmiourgoi*.

In Syracuse and in Samos, where society was divided into only two classes, the *geōmoroi* were the oligarchs, contrasted with the *dēmos*, the common people.

**geomorphic cycle**, also called GEOGRAPHIC CYCLE, or CYCLE OF EROSION, theory of the evolution of landforms. In this theory, first set forth by William M. Davis between 1884 and 1934, landforms were assumed to change through time from "youth" to "maturity" to "old age," each stage having specific characteristics. The initial, or youthful, stage of landform development began with uplift that produced fold or block mountains. Upon dissection by streams, the area would reach maturity and, ultimately, would be reduced to an old-age surface called a peneplain, with an elevation near sea level. The cycle could be

ever, are more numerous, covering the entire vase, with triple lines dividing patterned zones at regular intervals. The old Proto-Geometric design elements, the circle and arc, lost favour with the Geometric artist, while the zigzag and triangle remained and were incorporated along with some new elements, the meander and swastika. The overall visual effect of the

interrupted by uplift during any period of the life cycle and thus returned to the youthful stage; this return is called rejuvenation. The geomorphic cycle could be applied to all landforms such as hillslopes, valleys, mountains, and river drainage systems. It was assumed that, if the stage of a landform was known, its history followed directly according to a predetermined framework.

Though Davis acknowledged that rock type, structure, and the processes of erosion play a part in landform determination, he emphasized that time was the primary factor. It is now believed that time is no more important in landform development than the other factors. The cycle-of-erosion theory has long been accepted in the face of accumulating quantitative data that refutes it. It is generally held now that the initial conditions—or uplift—in a region do not necessarily predetermine the end products. Rather, there tends to be an eventual attainment of dynamic equilibrium between landforms and the processes that act upon them. When this happens, the physiographic history of a region is “erased.”

**geomorphology**, scientific discipline concerned with the description and classification of the Earth's topographic features.

A brief treatment of geomorphology follows. For full treatment, see *MACROPAEDIA: Earth Sciences*. For treatment of the physical, chemical, and biological processes that affect the surface features of the Earth, see *Geomorphic Processes*.

Much geomorphologic research has been devoted to the origin of landforms. Such studies focus on the forces that mold and alter the primary relief elements of the terrestrial surface. These forces include tectonic activity and surficial earth movements (e.g., landslides and rockfalls). They also involve weathering and the erosion and deposition of the resulting rock debris by wind, glacial ice, and streams. In recent years, increasing attention has been given to the effects of human action on the physical environment as well.

Many systems of classifying landforms have been devised since the late 19th century. Some systems describe and group topographic features primarily according to the processes that shaped or modified them. Others take additional factors into consideration (e.g., character of the surface rocks and climatic variations) and include the developmental stage of landforms as an aspect of their evolution over geologic time.

Geomorphology is closely allied with a number of other scientific disciplines that are concerned with natural processes. Fluvial and coastal geomorphology rely heavily on fluid mechanics and sedimentology; studies of mass movement, weathering, wind action, and soils draw on the atmospheric sciences, soil physics, soil chemistry, and soil mechanics; research on certain landform types entails the principles and methods of geophysics and volcanology; and the study of human impact upon landforms relies on the disciplines of geography and human ecology.

**Geophone**, trade name for an acoustic detector that responds to ground vibrations generated by seismic waves. Geophones—also called jugs, pickups, and tortugas—are placed on the ground surface in various patterns, or arrays, to record the vibrations generated by explosives in seismic reflection and refraction work. They also are used as military detection devices. See also seismic survey.

**geophysics**, major branch of the Earth sciences that applies the principles and methods of physics to the study of the Earth.

A brief treatment of geophysics follows. For full treatment, see *MACROPAEDIA: Earth Sciences*.

Geophysics deals with a wide array of geologic phenomena, including the temperature

distribution of the Earth's interior; the source, configuration, and variations of the geomagnetic field; and the large-scale features of the terrestrial crust, such as rifts, continental sutures, and mid-oceanic ridges. Modern geophysical research extends to phenomena of the outer parts of the Earth's atmosphere (e.g., the ionospheric dynamo, auroral electrojets, and magnetopause current system) and even to the physical properties of other planets and their satellites.

Many of the problems of geophysics are analogous to those of astronomy because the subject studied is rarely under direct observation, and conclusions must be drawn largely on the basis of mathematical interpretation of physical measurements. These include measurements of the Earth's gravitational field with gravimeters on land and sea and artificial satellites in space; magnetometric measurements of the planet's magnetic field; and seismological surveys of subsurface geologic structures using reflected and refracted elastic waves produced by earthquakes or by artificial means (see seismic survey).

Research conducted with geophysical techniques has proved extremely useful in providing evidence in support of the theory of plate tectonics (q.v.). Seismographic data, for instance, have demonstrated that the world's earthquake belts mark the boundaries of the enormous rigid plates that constitute the Earth's outer shell, while the findings of paleomagnetic studies have made it possible to trace the drift of the continents over geologic time.

**geopolitics**, the analysis of geographic influences on power relationships in international politics. Geopolitical theorists have sought to demonstrate the importance in the determination of national policy of such considerations as the acquisition of natural boundaries, access to important sea routes, and the control of strategically important land areas.

The term *geopolitics* was coined by the Swedish political scientist Rudolf Kjellén in his *Staten som Livsform* (1916; “The State as an Organism”). The term spread throughout central Europe between World Wars I and II and came into worldwide use during the latter. Between the wars, geopolitical arguments came to be employed in special pleading to promote the interests of particular nations or ideologies. Thus, for example, Karl Haushofer sought in his monthly journal of geopolitics, *Zeitschrift für Geopolitik*, to give a geopolitical rationale to the international claims of Germany; later, the Nazis adopted his theories for their own purposes. A warning was sounded by Sir Halford Mackinder (“The Geographical Pivot of History,” 1904, and *Democratic Ideals and Reality*, 1919) when he advanced a theory of a heartland in world politics. This heartland covered “Euro-Asia,” and, according to Mackinder, it was vital that the democratic nations control that area.

In the past, a nation's sphere of influence has been determined primarily by geopolitical factors. Such factors have, however, become relatively less significant in the foreign policies of states because of the improvements in communications and transportation that have enabled states to overcome the limitations imposed on them by geographic location or barriers.

#### BOHEMIA

● **George**, byname **GEORGE OF PODEBRADY**, Czech **JIRÍ Z PODEBRAD** (b. April 23, 1420, Poděbrady, Bohemia [now in Czech Republic]—d. March 22, 1471, Prague), king of Bohemia from 1458; as head of the conservative Utraquist faction of Hussite Protestants, he established himself as a power when Bohemia was still under Habsburg rule and was thereafter unanimously elected king by the estates. A nationalist and Hussite king of a prosperous state, he incurred the enmity of the papacy and Bohemia's Roman Catholic neighbours, which finally destroyed his power.

George became the leader of the Utraquists in 1444. Opposing the Roman Catholic pro-Habsburg party, whose prospective Bohemian king Ladislav was still a minor, he captured Prague in 1448, thereafter defeating the Habsburg faction. Accepting the situation, Ladislav's guardian, the future emperor Frederick III, entrusted George with the administration of Bohemia in 1451, while the Bohemian Diet appointed him regent. When Ladislav began his rule in 1453, George's importance waned; but, after the king's sudden death in 1457, he was elected king (March 2, 1458) despite accusations, probably false, that he had poisoned Ladislav. Bohemia prospered under his rule, and he enhanced his prestige by trying to organize an anti-Turkish league of Christian states (1642). But he refused Pope Pius II's demand that he abolish the Compactata, which had legitimized the Utraquist party. Although Pius died (1464) before his planned crusade against Bohemia began, the new pope, Paul II, supported a confederacy of nobles against George (1465), and on Dec. 23, 1466, the pope excommunicated him, pronounced him deposed, and forbade Roman Catholics to continue allegiance to him. Emperor Frederick III and Matthias Corvinus of Hungary joined the alliance against Bohemia, and on May 3, 1469, Matthias established himself in Brno as a rival king of Bohemia. George, however, refused to abdicate, and the struggle continued until his death.

#### GREAT BRITAIN/UNITED KINGDOM

● **George I**, in full **GEORGE LOUIS**, German **GEORG LUDWIG** (b. May 28, 1660, Osnabrück, Hanover [Germany]—d. June 11, 1727, Osnabrück), elector of Hanover (1698–1727) and first Hanoverian king of Great Britain (1714–27).

George I, detail of an oil painting after Sir Godfrey Kneller, 1714; in the National Portrait Gallery, London  
By courtesy of the National Portrait Gallery, London

George Louis of Brunswick-Lüneburg was the son of Ernest Augustus, elector of Hanover, and Sophia of the Palatinate, a granddaughter of King James I of England. George married his cousin Sophia Dorothea of Celle in 1682, but in 1694, accusing her of infidelity, he divorced her and imprisoned her in the castle of Ahlden, where she died 32 years later. He succeeded his father as elector of Hanover in 1698. The English Parliament's Act of Settlement (1701), seeking to ensure a Protestant succession to the throne in opposition to the exiled Roman Catholic claimant (James Edward, the Old Pretender), made George third in line for the throne after Princess Anne (queen from 1702–14) and his mother.

During the War of the Spanish Succession (1701–14) George fought with distinction against the French. England's Whig politicians began to court his favour, but many Tories remained loyal to the Old Pretender. When George's mother died on June 8, 1714, he became heir to the throne, and on the death of Queen Anne (Aug. 1, 1714) the Whigs, who had just gained control of the government, ushered him into power.

Naturally, George formed a predominantly Whig ministry. Although the Jacobite rebellions of 1715 and 1719 were readily suppressed, he was far from popular in England. Ugly rumours concerning his treatment of his wife were widely disseminated, and the greed of his two German mistresses reflected badly on his court. He attempted diligently, however, to fulfill his obligations to his new kingdom. Since he could not speak English, he communicated with his ministers in French. Although he stopped attending Cabinet meetings, he met with key ministers in private—a step that led to the decline of the Cabinet, which had largely controlled the government during Queen Anne's reign. His shrewd diplomatic judgment enabled him to help forge an alliance with France in 1717–18. Nevertheless, he often found it difficult to get his way in domestic politics, in which he had to deal with such strong-willed ministers as Robert Walpole (later earl of Orford), James Stanhope, and Viscount Charles Townshend. In 1716–17 Townshend and Walpole left his government in protest over Stanhope's alleged efforts to mold English foreign policy to the needs of George's Hanoverian possessions. By joining with George's son, the Prince of Wales (later King George II), whom the King detested, these dissidents formed an effective opposition movement within the Whig Party.

Shortly after this faction was reconciled to George in 1720, the South Sea Company suffered a financial collapse. In the ensuing scandal it became apparent that George and his mistresses had taken part in South Sea Company transactions of questionable legality, but Walpole's skill in handling the House of Commons saved the King from disgrace. As a result, George was forced to give Walpole and Townshend a free hand in the ministry. They pushed several of the King's friends out of office, and by 1724 George had come to rely completely on their judgment. George died of a stroke on a trip to Hanover. In addition to his son and successor, George II, he had a daughter, Sophia Dorothea (1687–1757), wife of King Frederick William I of Prussia and mother of Frederick the Great. R. Hatton's *George I* was published in 1978.

• **George II**, in full GEORGE AUGUSTUS, German GEORG AUGUST, also called (1706–27) MARQUESS AND DUKE OF CAMBRIDGE (b. Nov. 10 [Oct. 30, old style], 1683, Herrenhausen Palace, Hanover—d. Oct. 25, 1760, London), king of Great Britain and elector of Hanover from 1727 to 1760. Although he possessed sound political judgment, his lack of self-con-

fidence caused him to rely heavily on his ministers, most notable of whom was Sir Robert Walpole.

George Augustus was the only son of the German prince George Louis, elector of Hanover (King George I of Great Britain from 1714 to 1727), and Sophia Dorothea of Celle. He

George II, detail of an oil painting by Thomas Hudson, c. 1737; in the National Portrait Gallery, London

grew up in Hanover and married (1705) the beautiful and intelligent Caroline of Ansbach. Upon the accession of his father to the English throne he was designated prince of Wales. By 1717 George I and his son, who had for years detested each other, were quarrelling openly. The Prince's London residence, Leicester House, became the gathering place for a dissident Whig group headed by Walpole and Viscount Charles Townshend. The tepid reconciliation that took place between George I and the Prince in 1720 led to the inclusion of Walpole in George I's administration, and Walpole lost the Prince's favour when he became one of George I's leading ministers. The Prince, upon his accession as George II, would have dismissed Walpole from office had not Caroline intervened on the minister's behalf.

During the first two decades of his reign George II followed foreign and domestic developments closely. He supported Walpole's policy of peace and retrenchment and allowed the minister to use crown patronage to build up his majority in Parliament. Walpole won acknowledgment of George's legitimacy from many influential Tories who had been Jacobites—supporters of the exiled Stuart pretender to the English throne. Hence, no politician of prominence deserted George's cause during the abortive Jacobite Rebellion of 1745. Nevertheless, opposition to George and Walpole grew as the pattern of George I's reign repeated itself: George II and his son Frederick Louis, prince of Wales, quarrelled, and the Prince became a leader of an anti-administration faction. By 1742 these dissidents were strong enough to force Walpole to resign. George II quickly found another mentor in John Carteret (later Earl Granville), whose haughty ways proved unpopular in political circles. The two men brought England into the War of the Austrian Succession (1740–48), and in doing so they gave their opponents an opportunity to charge them with subordinating the interests of England to the needs of George's German possessions. In November 1744 George bowed to parliamentary pressure and accepted Carteret's resignation. Fifteen months later the King's ministers, by resigning (temporarily) en masse, forced George to accept into office Carteret's chief opponent, William Pitt (later earl of Chatham).

During the last decade of his life George II's interest in politics declined. He was little more than an observer of the events of the Seven Years' War (1756–63) against France, for it was Pitt who devised the brilliant strategy that eventually brought about a British victory. George died suddenly and was succeeded by

his grandson (son of Frederick Louis) King George III.

Throughout his life George II maintained a passion for anything military. He displayed courage while fighting the French at the Battle of Dettingen in 1743—the last time a British king appeared on the battlefield—and he organized each day with the precision of a drill sergeant. His other major interest was music; he loved opera and was a patron of the German composer George Frideric Handel. Charles Trench's *George II* appeared in 1973.

• **George III**, in full GEORGE WILLIAM FREDERICK, German GEORG WILHELM FRIEDRICH (b. June 4 [May 24, old style], 1738, London—d. Jan. 29, 1820, Windsor Castle, near London), king of Great Britain and Ireland (1760–1820) and elector (1760–1814) and then king (1814–20) of Hanover, during a period when Britain won an empire in the Seven Years' War but lost its American colonies, and then, after the struggle against Revolutionary and Napoleonic France, emerged as a leading power in Europe. During the last years of his life (from 1811) he was intermittently mad—his son, the future George IV, acting as regent.

*Early years.* George III was the son of Frederick Louis, prince of Wales, and Princess Augusta of Saxe-Gotha. From his parents and their entourage, the young George imbibed an unreasonable dislike of his grandfather, King George II, and of all his policies. George was a child of strong feelings but of slow mental development. This unequal growth of brain and heart made him difficult to teach and too easy to command and produced in him

George III, painting by Peter Edward Stroehling, 1807

By gracious permission of H.M. Queen Elizabeth II

an appearance of apathy; he could not read properly until he was 11. His affection for his immediate family circle dominated his life.

George was 12 when his father died, leaving him heir to the throne. It is clear that, in beginning with his 18th birthday to prepare conscientiously for his future responsibilities, he tormented himself with thoughts of his inadequacy. The curious blend of obstinate determination with self-distrust, a feature of his maturity, was already evident. His method of screwing up his courage was to set himself an ideal of conduct. This ideal George thought he had found personified in John Stuart, 3rd earl of Bute, who became his inspiration, his teacher, and later his chief minister.

George was potentially a better politician than Bute, for he had tenacity, and, as experience matured him, he could use guile to achieve his ends. But at his accession in 1760 in the midst of the Seven Years' War (1756–

63), between Great Britain and Prussia on one side and France, Austria, and Russia on the other, George did not know his own capacity nor the incapacity of his hero. As king, in 1761, he asked Bute for a review of all eligible German Protestant princesses "to save a great deal of trouble," as "marriage must sooner or later come to pass." He chose Charlotte Sophia of Mecklenburg-Strelitz and married her on Sept. 8, 1761. Though the marriage was entered into in the spirit of public duty, it lasted for more than 50 years, due to the King's need for security and his wife's strength of character. Bute's only other useful contribution to his royal pupil was to encourage his interest in botany and to implant in the court more respect for the graces of life, including patronage of the arts, than had been usual for the past half century.

*Political instability, 1760-70.* Politically, Bute encouraged the most disastrous of George's delusions. The government of England—at the time lacked effective executive machinery, and members of Parliament were always more ready to criticize than to cooperate with it. Moreover, the ministers were, for the most part, quarrelsome and difficult to drive as a team. The King's first responsibility was to hold coalitions of great peers together. But under Bute's influence he imagined that his duty was to purify public life and to substitute duty to himself for personal intrigue. The two great men in office at the accession were the elder Pitt and Thomas Pelham-Holles, duke of Newcastle. Bute and George III disliked both. Pitt was allowed to resign (October 1761) over the question of war against Spain. Newcastle followed into retirement when his control of treasury matters seemed to be challenged. The two former ministers were each dangerous as a focal point for criticism of the new government under the touchy captaincy of Bute. The government had two principal problems: to make peace and to restore peace-time finance.

Peace was made but in such a way as to isolate Britain in Europe, and for almost 30 years the country suffered from the new alignments of the European powers. Nor was George III happy in his attempt to express the agreed purposes of the country that to Bute had seemed so clear. George III might "glory in the name of Briton," but his attempts to speak out for his country were ill-received. In 1765 he was being vilified by the gutter press organized by the parliamentary radical John Wilkes, while "patriotic" gentlemen, moved by Pitt or Newcastle, suspected that the peace had been botched and that the King was conspiring with Bute against their liberties. For Bute the way out was easy—he resigned (April 1763).

George realized too late that his clumsiness had destroyed one political combination and made any other difficult to assemble. He turned to George Grenville, to his uncle, William Augustus, duke of Cumberland, to Pitt, and to the 3rd Duke of Grafton for help. All failed him. The first decade of the reign was one of such ministerial instability that little was done to solve the basic financial difficulties of the crown, made serious by the expense of the Seven Years' War. Overseas trade expanded, but the riches of the East India Company made no significant contribution to the state. The attempt to make the American colonists meet their own administrative costs only aroused them to resistance. Nor was there consistency in British colonial policy. The Stamp Act (1765) passed by Grenville was repealed by Lord Rockingham in 1766. Indirect taxes, in the form of the Townshend Acts (1767), were imposed without calculation of their probable yield and then repealed (except for that on tea) as a manoeuvre in home politics.

George III was personally blamed for this instability. According to the Whig statesman

Edmund Burke and his friends, the King could not keep a ministry because he was faithless and intrigued with friends "behind the curtain." Burke's remedy was to urge that solidity should be given to a Cabinet by the building up of party loyalty: the King as a binding agent was to be replaced by the organization of groups upon agreed principles. Thus the early years of George III produced, inadvertently, the germ of modern party politics. In truth, however, the King was not guilty of causing chaos by intrigue. He had no political contact with Bute after 1766; the so-called king's friends were not his agents but rather those who looked to him for leadership such as his predecessors had given. The King's failure lay in his tactlessness and inexperience, and it was not his fault that no one group was strong enough to control the Commons.

By 1770, however, George III had learned a good deal. He was still as obstinate as ever and still felt an intense duty to guide the country, but now he reckoned with political reality. He no longer scorned to make use of executive power for winning elections nor did he withhold his official blessing from those of whose characters he disapproved.

*North's ministry, 1770-82.* In 1770 the King was lucky in finding a minister, Lord North, with the power to cajole the Commons. North's policy of letting sleeping dogs lie lulled the suspicions of independent rural members who were always ready to imagine that the executive was growing too strong. As a result, 12 years of stable government followed a decade of disturbance.

Unfortunately, issues and prejudices survived from the earlier period that North could only muffle. America was the greatest and the fatal issue, and North could not avoid it because the English squires in Parliament agreed with their king that America must pay for its own defense and for its share of the debt remaining from the war that had given it security. George III's personal responsibility for the loss of America lies not in any assertion of his royal prerogative. Americans, rather, were disposed to admit his personal supremacy. Their quarrel was with the assertion of the sovereignty of Parliament, and George III was eventually hated in America because he insisted upon linking himself with that Parliament. North would have had difficulty in ignoring the colonists' insults in any case; with the King and the House of Commons watching to see that he was not weak, he inevitably took the steps that led to war in 1775.

By 1779 the typical English squires in Parliament had sickened of the war, but the King argued that though the war was indefensible on economic grounds it still had to be fought, that if disobedience were seen to prosper, Ireland would follow suit. He argued also, after the French had joined the Americans in 1778, that French finances would collapse before those of Britain. So the King prolonged the war, possibly by two years, by his desperate determination. The period from 1779 to 1782 left a further black mark upon the King's reputation. By 1780 a majority in Parliament blamed North's government for the calamities that had befallen the country, yet there was no responsible or acceptable alternative, for the opposition was reputed to be both unpatriotic and divided. At the time people believed that corruption alone supported an administration that was equally incapable of waging war or ending it. This supposed increase in corruption was laid directly at the King's door, for North wearily repeated his wish to resign, thus appearing to be a mere puppet of George III. When North fell at last in 1782, George III's prestige was at a low ebb. The failure of Shelburne's ministry (1782-83) reduced George to the lowest point of all. North joined with the liberal Whig Charles James Fox to form a coalition government, and George even contemplated abdication.

*George and the Younger Pitt, 1783-1806.*

Yet within a year the King had dramatically turned the tables, carrying out amid applause the most high-handed act of royal initiative in 18th-century England. When Fox and North produced a plan to reform the East India Company, which aroused fear that they intended to perpetuate their power by controlling Eastern patronage, the King reemerged as the guardian of the national interest. He let it be known that anyone who supported the plan in the House of Lords would be reckoned his enemy. The bill was defeated, and the ministers resigned. The King was ready with a new "patriotic" leader, William Pitt, the Younger. This initiative was dangerous. Pitt's government was in a minority in the Commons, and the discarded ministers were in a mood to threaten a constitutional upheaval. Everything depended on the verdict of a general election in March 1784. The country, moved by real feeling as well as by treasury influence, overwhelmingly endorsed the King's action. The King did not go on after his victory to further demonstrations of power. Though many of Pitt's ideas were unwelcome to him, he contented himself with criticism and a few grumbles. Pitt could not survive without the King, and the King, if he lost Pitt, would have been at the mercy of Fox. They compromised, but the compromise left most power, with the King's willing assent, in Pitt's capable young hands.

George loved his children possessively and with that hysterical force that he had always shown in relations with those close to him. He was depressed by the Prince of Wales's coming of age in 1783 as it meant emancipation from the family. The King's ruefulness was soon converted into rage. The Prince associated politically with Fox's Whigs and socially with Fox's gaming friends. In contrast to George III's rather straitlaced court, the Prince's circle was lively and dissolute. As his sons escaped him, one by one, George oscillated between excitement and despair. In the crises of his reign he frequently talked of abdication; but in 1788 it was announced that it was his reason that had fled its throne.

The stresses endured by this hard-working man seemed sufficient to account for his violent breakdown. Twentieth-century medical investigation, however, has suggested that the King had an inherited defect in his metabolism known as porphyria. An excess in purple-red pigments in the blood intoxicated all parts of the nervous system, producing the agonizing pain, excited overactivity, paralysis, and delirium that the King suffered in an acute form at least four times during his reign. The porphyria diagnosis, however, is not universally accepted by medical opinion.

The King's incapacity produced a political storm. But while Pitt and Fox battled over the powers that the Prince of Wales should enjoy as regent, the King suddenly recovered in 1789. He was left with the fear that he might again collapse into the nightmare of madness. For the last decade of the 18th century, he was bothered more about the details than about the main lines of policy. Pitt, whose policies contented him more and more, gradually absorbed in his own following most of North's old following and even some of Fox's. After the outbreak of war with Revolutionary France in 1793, all but the most radical Whigs joined the government, leaving Fox in hopeless, if eloquent, opposition.

The war with France seemed to most of the aristocracy and the upper middle class to be waged for national survival. The old king, an object of compassion in his collapse and obviously a well-meaning man, was soon a symbol of the old English order for which the country was fighting. Although his potential power in

politics was greatly increased, his will to wield it was enfeebled. George enjoyed himself in encouraging farmers to grow more food; or he talked for hours (ending his sentences rhetorically and fussily with the repeated words "what, what, what?") about past conflicts, or military tactics, or even of the shortcomings of Shakespeare; or he played to himself on his harpsichord; or he regulated the lives of his daughters, who found it so much less easy to escape than did his sons. From such quiet occupations he was aroused to activity by Pitt's Irish policy at the turn of the century.

The French war had made the issue of Roman Catholic emancipation urgent. Rebellion in Ireland, in Pitt's view, could not be cured simply by the union of the British and Irish Parliaments. Conciliation, by the political emancipation of the Roman Catholics, was a necessary concomitant of union. George III believed this proposal to be radical ruin and used all his personal prestige to have emancipation defeated. Pitt resigned (1801), and George persuaded Henry Addington (later 1st Viscount Sidmouth) to form a less adventurous Cabinet. The collapse of Addington's administration in 1804, after the short Peace of Amiens (1802-03), brought Pitt back into office (1804-06), but he returned at the cost of giving up his emancipation proposals. The King was decisive in this crisis only because it was an issue upon which he felt most deeply and upon which he instinctively expressed the feelings of the majority of the backbenchers in the House of Commons, though Pitt never pushed the matter to a real trial of strength.

*Last years, 1806-20.* On the death of Pitt (January 1806), the King accepted Fox as foreign secretary in a coalition "ministry of all the talents" (1806-07). He even came to feel affection for Fox and sincerely to lament his death in 1806. During this short period of Whig administration, the King allowed his ministers to discuss (abortively) peace with Napoleon and to abolish the slave trade; he asserted himself and forced their resignation only when they dared to propose some amelioration of the laws against Roman Catholics. This second break on the Roman Catholic issue came about in circumstances which witnessed to George's declining abilities. Still strong in body, he had become almost blind. He needed the help of a secretary in the task, which he would not reduce, of reading all the official papers. Lord Grenville thought the King had agreed to a paper that proposed the grant of higher rank in the army for papists. The King thought that his ministers were trying to trick him and that Sidmouth alone had explained to him the significance of the paper. He demanded from his ministers a promise not to bring up the subject again, for he feared he might be deceived into betraying his sworn duty to the Church of England. The perfectly proper refusal of ministers to pledge themselves for the future led to their supersession by the Tories, under Lord Portland (1807-09), Spencer Perceval (1809-12), and Lord Liverpool (1812-27), successively.

Much of the remainder of the King's lifetime was a living death. The death of his youngest child and frequent companion, Princess Amelia, in 1810, was a bitter blow; she had, in part, consoled him for his disappointment about his sons. Worse still was the return of the King's illness. In 1811 it was acknowledged that he was violently insane. The doctors continued to hope for recovery, but Parliament enacted the regency of the Prince of Wales (the future George IV) and decreed that the Queen should have the custody of her husband. He remained insane, with intervals of senile lucidity, until his death at Windsor Castle. George III's reign, on its personal side, was the tragedy of a well-intentioned man

who was faced with problems too great for him to solve but from which his conscience prevented any attempt at escape. (J.S.W.)

**BIBLIOGRAPHY.** The best account of George III's character is John Brooke, *King George III* (1972). Romney Sedgwick's introduction to his edition of *The Letters from George III to Lord Bute, 1757-1766* (1939), vividly relates the character to the political situation. Two quite wide surveys are Richard Pares, *King George III and the Politicians* (1953); and J. Steven Watson, *The Reign of George III* (1960). There has been a great deal of scholarly controversy about the nature of politics in the early years of George III's reign, in which the work of Lewis B. Namier has been outstanding. The major works are *The Structure of Politics at the Accession of George III*, 2nd ed. (1957), and *England in the Age of the American Revolution*, 2nd ed. (1961). This approach to the political history of George III's reign has been sharply and pertinently criticized by Herbert Butterfield in *George III and the Historians* (1957). Less interest has been displayed in the latter part of George III's reign, but John Ehrmann, *The Younger Pitt*, 2 vol. (1969), deals very thoroughly with the relations of George III with his most successful prime minister, William Pitt, the Younger. The question of the nature of George III's illness has been raised by Ida Macalpine and Richard Hunter, *George III and the Mad Business* (1969), but their arguments for porphyria as against insanity are not fully accepted by medical opinion.

INDEX  
first

• **George IV**, in full GEORGE AUGUSTUS FREDERICK, German GEORG AUGUST FRIEDRICH (b. Aug. 12, 1762, London, Eng.—d. June 26, 1830, Windsor, Berkshire), king of the United Kingdom of Great Britain and Ireland and king of Hanover from Jan. 29, 1820, previously the sovereign de facto from Feb. 5, 1811, when he became regent for his father, George III, who had become insane.

The eldest son of George III and Charlotte Sophia of Mecklenburg-Strelitz, he had become by age 17, as he said, "rather too fond of women and wine." His way of life and his close friendship with Charles James Fox and other loose-living Whig politicians caused his father to regard him with contempt. In 1784 the prince met the only woman whom he ever deeply loved, Maria Fitzherbert, whom he married secretly on Dec. 15, 1785. The marriage, however, was invalid: members of the royal family under the age of 25 were forbidden to marry without the king's consent.

On April 8, 1795, in order to induce Parliament to pay his debts, the prince contracted a loveless marriage with his cousin Caroline, daughter of the Duke of Brunswick and of George III's sister Augusta. A few weeks after the birth of their only child, Princess Charlotte (1796-1817), the couple separated. A few months after George IV's accession in 1820, Caroline, who had been living in Italy since 1814, returned to claim her rights as queen consort. A bill to deprive her of those rights and to dissolve the marriage on the ground of her adultery was introduced into the House of Lords but was never put to a vote in the Commons. The problem was solved by Caroline's death on Aug. 7, 1821.

In November 1810 George III became permanently insane, and shortly afterward the prince became regent under the terms of the Regency Act (1811). In February 1812, when the restrictions of that statute expired, George decided to retain his father's ministers rather than appoint survivors from among his old Whig friends (Fox had died in 1806). His decision benefited the nation, because the 2nd Earl Grey and other leading Whigs were prepared to abandon the war with France and leave Napoleon the master of the European continent. As it was, Great Britain and its al-

lies finally triumphed over Napoleon in 1815. George IV's accession on the death of his father did not add to the powers that he had possessed as regent.

George IV as prince regent, detail of an unfinished portrait by Sir Thomas Lawrence, 1814; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

He insulted and intrigued against the 2nd Earl of Liverpool, prime minister from 1820 to 1827. George Canning, who became foreign secretary in 1822 and prime minister in 1827, won George's approval, partly by cultivating the friendship of Sir William Knighton, the king's physician and keeper of the privy purse, on whose advice George relied excessively. But after 1827 he ceased to have any personal weight with either of the two great parties.

George IV's character was in part redeemed by his linguistic and other intellectual abilities and especially by his astute judgment in the arts; he patronized the architect John Nash, who developed Regent Street (1811-c. 1825) and Regent's Park, London; and he sponsored Sir Jeffry Wyattville's restoration of Windsor Castle. George's most famous effort was the exotic Royal Pavilion at Brighton with its Mughal Indian and Chinese decorations, designed by Nash.

**BIBLIOGRAPHY.** Biographies include Doris Leslie, *The Great Corinthian*, new ed. (1967); Joanna Richardson, *George the Magnificent* (1966); and Christopher Hibbert, *George IV*, 2 vol. (1972-73), all concentrating on George's personality more than his politics.

• **George V**, in full GEORGE FREDERICK ERNEST ALBERT (b. June 3, 1865, London, Eng.—d. Jan. 20, 1936, Sandringham, Norfolk), king of the United Kingdom from 1910 to 1936, the second son of Prince Albert Edward, later King Edward VII.

George V  
Camera Press

He served in the navy until the death (1892) of his elder brother, Prince Albert Victor, brought the need for more specialized training as eventual heir to the throne. Created Duke of York (May 1892), he married (July 1893) Princess Mary of Teck, who had been his brother's fiancée. Created Duke of Cornwall and Prince of Wales after his father's accession (1901), he succeeded his father on May 6, 1910, and was crowned on June 22, 1911.

Formidable difficulties faced the new king early in his reign. The constitutional struggle to curb the power of the House of Lords was unresolved, and the Liberal government secured an undertaking from the king that, should the lords not yield, he would create sufficient new peers to overcome the opposition. After the Liberal success in the election of December 1910, the House of Lords relented and passed the Parliament Act (1911), and the king did not have to fulfill his pledge. Respect for King George greatly increased during World War I, and he visited the front in France several times.

After World War I the king was confronted by an outbreak of serious industrial unrest. He was also faced with a difficult decision on the resignation of Andrew Bonar Law in 1923, when he had to find a new prime minister. Both Lord Curzon and Stanley Baldwin had supporters among the elder statesmen whom George consulted, but, believing Baldwin had more support in the Conservative Party and that the prime minister should be in the House of Commons, the king selected him.

King George was seriously ill at the end of 1928, and for the rest of his reign he had to be extremely careful of his health. In 1931 the collapse of the pound and the consequent financial crisis split the Labour administration. To secure strong government, he persuaded Ramsay MacDonald and a part of his Cabinet to remain in office and join with Conservative and Liberal ministers in the formation of a national coalition government. The celebration of George's silver jubilee (May 1935) enabled the public to express its affection and admiration for him.

King George had five sons—King Edward VIII (later Duke of Windsor); King George VI; Henry, Duke of Gloucester; George, Duke of Kent; and Prince John, who died young—and one daughter, Mary, princess royal, who married the 6th Earl of Harewood.

**BIBLIOGRAPHY.** Kenneth Rose, *King George V* (1983), studies both the monarch and the man.

• **George VI**, also called (1920–36) **PRINCE ALBERT, DUKE OF YORK**, in full **ALBERT FREDERICK ARTHUR GEORGE** (b. Dec. 14, 1895, Sandringham, Norfolk, Eng.—d. Feb. 6, 1952, Sandringham), king of the United Kingdom from Dec. 11, 1936.

The second son of the future king George V, the prince served in the Royal Navy (1913–17), the Royal Naval Air Service (1917–19), and the Royal Air Force (1919) and then attended Trinity College, Cambridge (1919–20). On June 3, 1920, he was created Duke of York. He sponsored the annual Duke of York's Camp (1921–39), at which equal numbers of public (private) school boys and boys from industrial areas spent a week together as his guests. On April 26, 1923, he was married to Lady Elizabeth Angela Marguerite Bowes-Lyon, youngest daughter of the 14th Earl of Strathmore and Kinghorne. They had two children: Princess Elizabeth (afterward Queen Elizabeth II) and Princess Margaret (afterward Countess of Snowdon).

The Duke of York was officially proclaimed king on Dec. 12, 1936, following the abdication of his brother Edward VIII. He took the name of George VI and was crowned on May 12, 1937. Before the outbreak of World War II, the king affirmed Anglo-French solidarity and formed a close friendship with U.S. President Franklin D. Roosevelt, but he supported Prime Minister Neville Chamberlain's "appeasement" policy toward Germany and Italy. In May 1940, when the House of Commons forced Chamberlain to resign, the king wished to appoint Edward Halifax (later 1st Earl of Halifax) to the premiership but was induced to select Winston Churchill, whose wartime leadership he then supported unreservedly. During the war he visited his armies on several battle fronts.

Although King George had ceased to be emperor of India when India and Pakistan became separate independent countries, he was formally recognized, on April 27, 1949, as

George VI  
Keystone

head of the Commonwealth of Nations by the governments of its member states. From 1948 on, the king's health deteriorated, and he died a few months after undergoing an operation for lung cancer.

Although he was an important symbolic leader of the British people during World War II, his reign was perhaps most important for the accelerating evolution of the British Empire into the Commonwealth of Nations and the postwar transformation of Great Britain into a welfare state. He earned respect by scrupulously observing the responsibilities and limitations of a constitutional monarch and by overcoming the handicap of a severe stammer.

**BIBLIOGRAPHY.** Denis Judd, *King George VI, 1895–1952* (1982); and Patrick Howarth, *George VI* (1987), study his private life and political influence.

## GREECE

• **George I**, original name **PRINCE WILLIAM OF DENMARK**, Danish **PRINS VILHELM AF DANMARK** (b. Dec. 24, 1845, Copenhagen, Den.—d. March 18, 1913, Salonika, Greece), king of Greece, whose long reign (1863–1913) was the formative period for the development of Greece as a modern European state. His descendants occupied the throne until the military coup d'état of 1967 and eventual restoration of the republic in 1973.

Born Prince William, the second son of King Christian IX of Denmark and the brother of Queen Alexandra of England, he was nominated to the Greek throne by Britain, France, and Russia after the first Greek king, Otto, was deposed in 1862. The National Assembly accepted William as king of the Hellenes in March 1863, and he ascended the throne as George (Georgios) I on October 31. Although the early years of his reign were dominated by his harsh and unpopular adviser Count Sponneck, who was obliged to return to Denmark in 1877, he refrained from transgressing the prerogatives of the National Assembly and became one of the most successful constitutional monarchs in Europe.

• **George II** (b. July 20, 1890, Tatoi, near Athens, Greece—d. April 1, 1947, Athens), king of Greece from September 1922 to March 1924 and from October 1935 until his death. His second reign was marked by the ascendancy of the military dictator Ioannis Metaxas.

The eldest son of King Constantine I, George was excluded from the succession during World War I for his allegedly pro-German sympathies, but he came to the throne when his father was deposed by General Nikólaos Plastíras in September 1922. Feeling ran high against the royal family, however, and, after

a royalist coup d'état had been suppressed in October 1923, George felt compelled to leave Greece on December 19 with his queen, Elizabeth. In March 1924 the Greek National Assembly voted the end of the monarchy and proclaimed Greece a republic. The king remained in exile until the conservative Populist Party, with the support of the army, gained control of the Assembly and declared the restoration of the monarchy in October 1935; a plebiscite, which was most probably manipulated by the prime minister, General Geórgios Kondílis, was held in November in an effort to demonstrate that the great majority of the people favoured his return.

In 1936 General Ioannis Metaxas seized power after asserting that the nation was on the verge of being taken over by the communists. The king's support of Metaxas put the throne in a controversial position, particularly after Metaxas banned political parties, dissolved Parliament, suspended constitutional rights, and even decreed the censorship of Pericles' great funeral oration to the Athenians as recorded by Thucydides. The king was forced into exile after the German invasion

George II  
Dimitri Papadimos, Athens

of Greece in April 1941, going first to Crete, then to Alexandria, and finally to London. After the war republican sentiments again threatened his throne, but he was restored by a plebiscite supervised by the Allies and returned to Greece in September 1946. Upon his death, he was succeeded by his brother Paul.

## HANOVER

• **George I–IV**; see **George I–IV** (Great Britain/United Kingdom).

• **George V** (b. May 27, 1819, Berlin—d. June 12, 1878, Paris), last king of Hanover (1851–66), only son of Ernest Augustus, king of Hanover and Duke of Cumberland.

His youth was passed in England and in Berlin until 1837, when his father became king of Hanover. He lost sight in one eye during a childhood illness and in the other by an accident in 1833. Blindness debarred him from a knowledge of the world; he formed a fantastic conception of the dignity of the house of Welf and had ideas of founding a great Welf state in Europe. From his accession in November 1851 he was constantly disputing with the diet, contrary to whose wishes he refused Prussia's demand for the unarmed neutrality of Hanover during the Austro-Prussian War of 1866. This led to an immediate Prussian invasion, the surrender of George's army on June 29, 1866, and Prussia's formal annexation of Hanover in September. The king subsequently lived in Austria or in France. He died in Paris and was buried in St. George's Chapel, Windsor. His son, Ernest Augustus, Duke of Cumberland (1845–1943),

continued to maintain the claim of his house to the kingdom of Hanover.

#### SAXE-MEININGEN

• **George II** (b. April 2, 1826, Meiningen, Saxe-Meiningen [now in Germany]—d. June 25, 1914, Bad Wildungen, Waldeck), duke of Saxe-Meiningen, theatrical director and designer who developed many of the basic principles of modern acting and stage design.

George II, 1900

Archiv für Kunst und Geschichte, Berlin

A wealthy aristocrat and head of a small German principality, Saxe-Meiningen early studied art and in 1866 established his own court theatre group, which he served as producer, director, financial backer, and costume and scenery designer. Influenced by the contemporary English theatre, he insisted on realistic lighting, speech, and stage mechanics and historically accurate costumes and sets. He also replaced virtuoso solo performances on a flat stage with ensemble acting on a multilevel stage that greatly facilitated the handling of crowd scenes. When the group was disbanded in 1890, it had toured 36 European cities. The Meiningen troupe's methods had their effect upon the younger generation of European stage directors, particularly André Antoine, who founded the first theatre of naturalism (Théâtre-Libre, Paris, 1887), and Konstantin Stanislavsky, an influential proponent of realism in the Russian theatre.

**George**, town, Western Cape province, South Africa. The town lies distantly east of Cape Town and immediately inland from the Indian Ocean. It was founded in 1811 as the first British settlement in the Cape Colony and named after King George III, as was George Peak nearby. Hops, not otherwise grown in South Africa, are cultivated in the area. Boats, shoes, and furniture are manufactured in the town. George serves as an educational and service centre for the surrounding rural area. It has a mild and equable climate and is traditionally a place of retirement for whites. The majority of the population are people of mixed race. Pop. (1985) 41,920.

**George**, SAINT (fl. probably 3rd century; d. traditionally Lydda, Palestine [now Lod, Israel]; feast day April 23), early Christian martyr who during the Middle Ages became an ideal of martial valour and selflessness. He is the patron saint of England.

Nothing of George's life or deeds can be established, but legends about him as a warrior-saint, dating from the 6th century, became popular and increasingly extravagant. Jacob de Voragine's *Legenda aurea* (1265–66; *Golden Legend*) repeats the story of his rescuing a Libyan king's daughter from a dragon and then slaying the monster in return for a promise by the king's subjects to be baptized. George's slaying of the dragon may be a Christian version of the legend of Perseus, who was said to have rescued Andromeda from a sea monster near Lydda. It is a theme much

represented in art, the saint frequently being depicted as a youth wearing knight's armour with a scarlet cross.

George was known in England by at least the 8th century. Returning crusaders likely popularized his cult (he was said to have been seen helping the Franks at the Battle of Antioch in 1098), but he was probably not recognized as England's patron saint until after King Edward III (reigned 1327–77) made him the patron of the newly founded Order of the Garter. He was also adopted as protector of several other medieval powers, including Portugal, Genoa, and Venice. With the passing of the chivalric age and finally the Protestant Reformation, the cult of Saint George dwindled. His feast is given a lesser status in the calendar of the Church of England; a holy day of obligation for English Roman Catholics until the late 18th century, it is now an optional memorial for local observance.

**George of Cappadocia** (b. Lydda?, Palestine [now Lod, Israel]—d. Dec. 24, 361, Alexandria, Egypt), opponent of and controversial successor (357) to Bishop Athanasius the Great of Alexandria, whom the Roman emperor Constantius II had exiled for attacking Arianism. As an extreme Arian, George was detestable both to the orthodox and to the Semi-Arians. A violent and avaricious man, he insulted, persecuted, and plundered orthodox and pagan alike. The death on Nov. 3, 361, of his protector, Constantius, made him vulnerable to insurrection, and he was murdered by an Alexandrian mob.

**George of Laodicea** (b. Alexandria, Egypt—d. c. 361, Laodicea [now Latakia], Syria), bishop of Laodicea who was one of the principal champions of the homoiousian, or moderate Arian, theological position.

George was ordained in Alexandria by Bishop Alexander but was excommunicated on charges of immorality and for advocating Arianism. He failed to reconcile Arius with Alexander. Appointed bishop of Laodicea (c. 335), he attended numerous synods in the following decades, and, as an advocate of the homoiousian theology, he opposed the orthodox bishop Athanasius the Great of Alexandria. He protected Bishop Eusebius of Emesa during his exile for being a Semi-Arian and wrote a biography of him, of which fragments are extant. A defense of the homoiousian doctrine, which he composed in conjunction with Bishop Basil of Ancyra (now Ankara, Turkey) and others, was preserved by Bishop St. Epiphanius of Salamis, Cyprus.

**George of PODEBRADY**: see *George under George* (Bohemia).

**George of Trebizond** (b. 1396, Candia, Crete [now Iráklion, Greece]—d. 1486, Rome [Italy]), Byzantine humanist, Greek scholar, and Aristotelian polemic. His academic influence in Italy and within the papacy, his theories on grammar and literary criticism, and his Latin translations of ancient Greek works, although at times strongly criticized, contributed substantially to Italian humanism and the Renaissance.

Named for his family's origin in Trebizond (now Trabzon in Turkey), on the Black Sea, George went to Italy as a youth and soon distinguished himself as a scholar, becoming professor of Greek at Vicenza in 1420 and at Venice in 1433. He eventually succeeded to the literary primacy of the humanist scholar Francesco Filelfo (1398–1481). Hearing of his reputation, Pope Eugenius IV invited him to Rome as his private secretary and to join the faculty of philosophy at the Sapienza academy. In the course of his criticism of the classical Latin rhetorician Quintilian (1st century AD), George incurred the wrath of the Roman humanist Lorenzo Valla. Harsh contention intensified over his hurried translations of Aristotle's *Rhetoric* and *The History of Animals*,

Plato's *Laws*, Ptolemy's *Ahmagest*, and various tracts from the Greek Church Fathers, resulting in errors and linguistic deformities. Such lapses in scholarship cost him the patronage of Pope Nicholas V (1447–55) and forced him to leave Rome in 1453. On his final return in 1466, the ferocity of criticism mounted as the Platonists Gemistus Plethon and Cardinal Bessarion attacked George's assertions of the superiority of Aristotle's realism over Plato's idealist theory of knowledge. Significant success, however, came when George published, in 1471, a radically revised Latin grammar in which he abandoned the medieval method for the purer form of the 6th-century Latinist Priscian. An earlier work on rhetoric based largely on Aristotelian and later Greek principles attained lasting recognition, even from his critics, who admitted to the erudition and brilliance of his vast oeuvre.

**George THE MONK**, also called **GEORGE THE SINNER**, Greek **GEORGIOS HAMARTOLOS** (fl. 9th century), Byzantine historian, author of a world chronicle that constitutes the prime documentary source for mid-9th-century Byzantine history, particularly the iconoclast (Greek: "image destroyer") movement.

George's chronicle, with a theological naïveté characteristic of the age, records events from the Creation to the reign of the emperor Michael III (842–867). Incorporating texts from earlier Byzantine historians, he integrated data of his own experience from 813 to 842 through an original monastic and theological perspective. Strongly opposed to iconoclasm, George recounted in detail and with satisfaction the resolution of the controversy in favour of the orthodox use of religious images following the reign of the emperor Theophilus (829–842).

The chronicle, which also provides data on the growing Islamic-Christian conflict, enjoyed widespread diffusion among the neighbouring Slavic peoples throughout the medieval period. Accordingly, its influence on Byzantine chronography, prompting a multiplicity of versions and translations, renders the reconstruction of the primitive text most difficult. George's chronicle assumes increased value in that many of the sources it excerpted are now lost to history. Some versions contain a "continuation" to the year 948 written by an anonymous author more politically oriented than George.

**George THE PISIDIAN**, Greek **GEORGIOS PISIDES** (fl. early 7th century), Byzantine epic poet, historian, and cleric whose classically structured verse was acclaimed as a model for medieval Greek poetry, but whose arid, bombastic tone manifested Hellenism's cultural decline.

A deacon and archivist of Constantinople's cathedral Hagia Sophia, George chronicled imperial events and the deeds of his ruler, the emperor Heraclius (610–641), whom he accompanied on his successful campaigns against the threatening Persian and Caucasian tribes. He thus eulogized the Byzantine resurgence in "The Expedition of Heraclius Against the Persians" (622) and "The Heracliad" (627), an ode commemorating the victory over the Parthians and the recovery of the "Holy Cross" that they had seized earlier in Jerusalem.

George's major work, the *Hexaëmeron* (Greek: "Of Six Days"), a rhapsody on the beauty of creation and the Creator's wisdom, was popularized through translations into Armenian and Slavic languages. Other writings included the moralistic elegy "De vanitate vitae" ("On the Vanity of Life"), in the manner of the Old Testament book of Ecclesiastes; a "Hymn to the Resurrection," celebrating Christ's triumph over life and death; and, to support Heraclius' religious politics, a metrical polemic, "Against Wicked Severus," attacking the patriarch of Antioch and leader of the independent Syrian Monophysite Church.

With his impeccable style and fluidity of expression, George was compared to the 5th-century-BC Greek tragedian Euripides. Although he enjoyed the reputation of being perhaps the outstanding Byzantine poet of the iambic form, his obvious imitation of classical Greek authors and his pretentious imagery evoked negative reactions from later critics.

**George THE SYNCHELLUS** (fl. late 8th century—d. after 810), Byzantine historian and author of a world chronicle of events from the creation to the reign of the Roman emperor Diocletian (reigned 284–305). Together with the parallel work by Eusebius of Caesarea, George's work constitutes the prime instrument for interpreting Christian chronography concerning the primitive church.

Having first lived in the Holy Land of Palestine, George became private secretary to Tarasius, patriarch of Constantinople (reigned 784–806), thus acquiring the title Syncellus (Greek: Cellmate), an official Byzantine position of cleric confidant to a high ecclesiastic. After the death of Tarasius, George retired to a monastery and composed his "Chronicle," which treats extensively of Christ's birth and the New Testament period but gives scant attention to the post-apostolic age. Following George's death, his "Chronicle" was extended by Theophanes the Confessor to his own time (813); subsequent contributors carried it to the year 961.

**George, Henry** (b. Sept. 2, 1839, Philadelphia—d. Oct. 29, 1897, New York City), land reformer and economist who in *Progress and Poverty* (1879) proposed the single tax: that the state tax away all economic rent—the income from the use of the bare land, but not from improvements—and abolish all other taxes.

Leaving school before his 14th birthday, George worked for two years as a clerk in an importing house and then went to sea. Back in Philadelphia in 1856, he learned typesetting and in 1857 signed up as a steward on another ship, quitting it in San Francisco to join the gold rush in Canada, where, however, he arrived too late. In 1858 he returned to California, where he worked for newspapers and took part in Democratic Party politics until 1880. In 1871 he and two partners started the *San Francisco Daily Evening Post*, but credit difficulties forced them to close it in 1875. A political appointment as state gas-meter inspector enabled him to work on *Progress and Poverty*.

George's book caught the spirit of discontent that had arisen from the great depression of 1873–78. It had an enormous sale and was translated into many languages. Its vogue was enhanced by George's pamphlets, his frequent contributions to magazines, and his lecture tours in both the United States and the British Isles.

As a basis for his argument, George gave new meaning to the orthodox, or "Ricardian," doctrine of rent. He applied the law of diminishing returns and the concept of "margin of productivity" to land alone. He argued that since economic progress entailed a growing scarcity of land, the idle landowner reaped ever greater returns at the expense of the productive factors of labour and capital. This unearned economic rent, he held, should be taxed away by the state. George envisaged that the government's annual income from this "single tax" would be so large that there would be a surplus for expansion of public works. His economic argument was reinforced and dominated by humanitarian and religious appeal.

George's specific remedy had no significant practical result, and few economists of reputation supported it. Nevertheless, his forceful emphasis on "privilege," his demand for equality of opportunity, and his systematic economic analysis proved a stimulus to orderly reform.

**BIBLIOGRAPHY.** R.A. Sawyer, *Henry George and the Single Tax* (1926); Anna George de Mille, *Henry George*, ed. by D.C. Shoemaker (1950); S.B. Cord, *Henry George: Dreamer or Realist?* (1965).

**George, Lake**, freshwater lake, southeastern New South Wales, Australia, located about 25 mi (40 km) northeast of Canberra, just east of the Lake George Range, a low ridge in the Great Dividing Range. Occupying a structural trough formed by faulting during the middle Miocene Epoch (about 16,000,000 years ago) or a little earlier, the lake drains a 380-sq-mi (984-sq-km) basin between the headstreams of the Yass and Shoalhaven rivers, although it has no external drainage itself. The lake, substantially larger during late Pleistocene times (about 10,000 years ago), maintains a particularly delicate balance among rainfall, evaporation, and streamflow, displaying wide fluctuations in surface elevation (about 2,208 ft [673 m]) and surface area (mean area about 31 sq mi). When full, the lake has a length of about 16 mi, a width of about 6 mi, and a depth of 20 to 26 ft. However, in some years (e.g., 1838–39, 1846–50, 1930–34, 1936–47, and 1982), the lake is dry and its alluvial floor becomes rich pastureland. The Aboriginal name of the lake is Werriwa. The lake was first visited by a European, Joseph Wild, in 1820 and named for George IV.

**George, Lake**, lake in northeastern New York, U.S.; it is 32 mi (51 km) long, 1 to 4 mi wide and extends northward from Lake George village to Ticonderoga, where it is connected to Lake Champlain through a narrow channel which descends 220 ft (67 m) in a series of cataracts and waterfalls. Located in the foothills of the Adirondacks at an elevation of 317 ft above sea level and surrounded by low mountains, including Mts. Prospect (1,705 ft) and Black (2,665 ft), the lake is of glacial origin, has a maximum depth of about 200 ft, and is fed by mountain streams and submerged springs. Dotted with islands, it is noted for its scenic beauty and is a popular resort area.

It was known to the Indians as Andiatarocete (meaning "place where the lake contracts"). The first Europeans to see the lake were probably Father Isaac Jogues, a French Jesuit missionary, and his companions, René Goupil and Guillaume Couture, who were being taken by their Indian captors to the town of the Mohawks in 1642. Father Jogues returned to the lake in 1646 and christened it Lac du Saint-Sacrement. In 1755 Gen. Sir William Johnson renamed it for King George II. James Fenimore Cooper refers to it in his novels as Lake Horicon.

Strategically located at the head of the valley extending northward to the St. Lawrence, the lake was the scene of numerous battles during the French and Indian War and the American Revolution. The Battle of Lake George (commemorated by a monument and state park) took place just south of the lake on Sept. 8, 1755, when Gen. William Johnson defeated a force of French Canadians and Indians led by Baron Ludwig August Dieskau. Following the battle, Johnson built Ft. William Henry (now restored), which was replaced (1759) by Ft. George (ruins remain). During the American Revolution, the Green Mountain Boys under Ethan Allen captured Ft. Ticonderoga at the falls on the lake's outlet (see Ticonderoga).

**George, Stefan** (b. July 12, 1868, Büdesheim, near Bingen, Hesse—d. Dec. 4, 1933, Minusio, near Locarno, Switz.), lyric poet chiefly responsible for the revival of German poetry at the close of the 19th century.

He studied philosophy and the history of art in Paris, Munich and Berlin and travelled widely, becoming associated with Mallarmé and the Symbolists in Paris and with the Pre-Raphaelites in London. Returning to Germany, where he divided his time between

Berlin, Munich, and Heidelberg, he founded a literary school of his own, the George-Kreis, held together by the force of his authoritarian personality. Many well-known writers belonged to it or contributed to its journal, *Blätter für die Kunst*, published from 1892 to 1919. The chief aim of the journal was to revitalize the German literary language, felt to be in decline.

Stefan George, c. 1925–30

By courtesy of the Stadarchiv, Munich

George aimed to impose a new classicism on German poetry, avoiding impure rhymes and metrical irregularities. Vowels and consonants were arranged with precision to achieve harmony. The resulting symbolic poem was intended to evoke a sense of intoxication. These poetic ideals were a protest not only against the debasement of the language but also against materialism and naturalism, to which George opposed an austerity of life and a standard of poetic excellence, preaching a humanism inspired by Greece, which he hoped would be realized in a new society. His ideas, and the affectations into which they led some of his disciples, his claim of superiority, and his obsession with power were ridiculed, attacked, and misused by those who misunderstood them. But George himself was strongly opposed to the political developments—above all, the rise of Nazism—which his ideas are sometimes thought to reflect. When the Nazi government offered him money and honours, he refused them and went into exile.

George's collected works fill 18 volumes (*Gesamtausgabe*, 1927–34), including five of translations and one of prose sketches. His collections of poetry, of which *Hymnen* (1890), *Pilgerfahrten* (1891), *Algabal* (1892), *Das Jahr der Seele* (1897), *Der Teppich des Lebens* (1899), *Der siebente Ring* (1907), *Der Stern des Bundes* (1914), and *Das neue Reich* (1928) are the most important, show his poetic and spiritual development from early doubts and searching self-examination to confidence in his role as a seer and as leader of the new society he projected.

Personally, and spiritually, he found the fulfillment of his striving for significance in "Maximin" (Maximilian Kronberger; 1888–1904), a beautiful and gifted youth whom he met in Munich in 1902. After the boy's death George claimed that he had been a god, glorifying him in his later poetry and explaining his attitude to him in *Maximin, ein Gedenkbuch* (privately published, 1906).

**George Cross**, a British civilian and military decoration, instituted in 1940 by King George VI for "acts of the greatest heroism or of the most conspicuous courage in circumstances of extreme danger." The award, which can be conferred posthumously, is usually given to civilians, although it can be bestowed on military personnel for acts for which military decorations are not usually awarded. The George Cross superseded the Medal of the Order of the British Empire for Gallantry (commonly known as the Empire Gallantry Medal).

The island of Malta received the George Cross in recognition of its inhabitants' gallantry in World War II. Recipients of this award may add G.C. after their names; the cross ranks second only to the Victoria Cross (the highest British military decoration). The cross is silver, with one side depicting St. George slaying the dragon and with the inscription "For Gallantry;" the other side gives the recipient's name and the date of the award.

The George Medal, instituted at the same time as the George Cross, is analogous to it but is awarded for services not quite so outstanding as those which merit the George Cross. Recipients of this medal can add G.M. after their names. The medal is silver; one side has the effigy of the reigning British monarch, and the other side has St. George and the dragon with the inscription "The George Medal."

**George River**, French RIVIÈRE GEORGE, river in Nord-du-Québec region, northeastern Quebec province, Canada. It rises near the Labrador (Newfoundland) border, flows northward parallel to the boundary for 350 miles (563 km), and empties into the eastern side of Ungava Bay. Named after King George III by Moravian missionaries in 1811, the river flows mostly through a treeless tundra in a course broken by numerous falls and rapids. At its mouth is Kangisualujuaq, established in 1838 as a Hudson's Bay Company trading post.

**George Town**, also spelled GEORGETOWN, also called PENANG, or PINANG, leading port of Malaysia, situated on a triangular promontory in the northeastern sector of the island of Penang (Pinang). Its sheltered harbour is separated from the west-coast Malayan mainland by a 3-mile (5-kilometre) channel through which international shipping approaches from the north to avoid the many shallows of the southern route.

The town was founded as Fort Cornwallis in 1786 by Captain Francis Light of the British East India Company and flourished as a port of call for shipping on the India-China run. It became for a time the capital and commercial centre of the Straits Settlements. A restored Fort Cornwallis, St. George's Church (1817), and the Esplanade recall the town's colonial past. As a thriving entrepôt, George Town attracted Chinese (mainly Hokkien and Cantonese) and Indian traders. Although Chinese and European culture predominates, there is a sizable Malay minority in the city.

Industries in the southern suburbs include tin smelting, rice and coconut-oil milling, and the manufacture of soap and of rattan and bamboo articles. Industrial estates at Bayan Lepas are the site of electronics assembly plants. Most of the mainland's exports are ferried or brought by lighter to George Town from the smaller ports of Butterworth and Perai, which cannot handle oceangoing vessels. By the late 20th century, the bulk of the Malay Peninsula's cargo, previously channeled through the east-coast ports, moved through George Town. Major exports include tin, rubber, and copra. The University of Science of Malaysia (founded 1969) is at Minden Barracks on the outskirts. Also on the outskirts is George Town's most spectacular temple, the Kek Lok Si Temple, or, as it is sometimes called, the Million Buddhas Precious Pagoda, a complex of structures on three levels with thousands of gilded Buddhas. Pop. (1991 prelim.) 219,376.

**George Washington Birthplace National Monument**, national monument consisting of 538 acres (218 hectares) of plantation land in Westmoreland county, eastern Virginia, U.S. It lies along the Potomac River 38 miles (61 km) east-southeast of Fredericksburg. John Washington, great-great-grand-

father of George, was the first family member to settle in the area, in about 1656. In 1731 Augustine, John's grandson, married his second wife, Mary Ball, and settled at Popes Creek, where his son George was born Feb. 22, 1732. "Wakefield," the house where George spent the first three years of his life, was built (1722–26) by Augustine but destroyed by fire (1779) after the family had moved to Mount Vernon in 1735. The present Memorial Mansion, reconstructed (1931–32) near a stone marker set by the Washington family in 1815, represents a typical 18th-century Virginia plantation dwelling with a period garden. The nearby Colonial Living Farm also depicts the environment of Washington's infant years. Foundations of what is believed to be the birthplace house and other buildings have been unearthed.

The monument was established in 1930 through the efforts of the Wakefield National Memorial Association (organized in 1923 to recover the birthplace grounds) aided by John D. Rockefeller, Jr.

**George Washington Bridge**, vehicular suspension bridge crossing the Hudson River, U.S., between The Palisades park near Fort Lee, N.J., and Manhattan island, New York City (between 178th and 179th streets). The original structure was built (1927–31) by the Swiss-born engineer Othmar H. Ammann according to the modified designs of architect Cass Gilbert. It was constructed to carry eight lanes of traffic. A lower deck with six more traffic lanes was added in 1958–62, along with a modernistic bus terminal on the Manhattan side (designed by Pier Luigi Nervi).

When first built, the main span of 3,500 feet (1,067 m) doubled the record for suspension bridges. Overall, the bridge now extends 4,760 feet (1,450 m) between anchorages, with the decks 115 feet (35 m) and 212 feet (65 m) above mean high water and the lattice-steel towers rising 604 feet (184 m) high above the water. On the New York side the tower stands

George Washington Bridge, seen from New Jersey, looking toward Manhattan

© Jeffrey Sylvester, FPG International

on land; on the New Jersey side the tower rises out of the river 76 feet (23 m) from shore. The bridge was built and is operated by the Port of New York Authority.

**George William**, German GEORG WILHELM (b. Nov. 13, 1595, Kölln an der Spree, Brandenburg [now in Berlin, Ger.]—d. Dec. 1, 1640, Königsberg, Prussia [now Kaliningrad, Russia]), elector of Brandenburg (from 1619) through much of the Thirty Years' War.

Though a Calvinist, George William was persuaded by his Roman Catholic adviser Adam von Schwarzenberg to stay out of the struggle between the Holy Roman emperor and the German Protestant princes. His neutrality won him the hostility of both sides. In 1631 Gustavus II Adolphus of Sweden occupied

Brandenburg, forcing the elector to join the Protestants, but, after the Swedish defeat by an imperial army at Nördlingen (1634), George William withdrew from the conflict.

**Georgetown**, town, port on MacCarthy Island in the Gambia River, central Gambia. It was founded in 1823 by Captain Alexander Grant as a settlement for freed slaves. Georgetown's Wesleyan Mission (1823) introduced

Sifting peanuts in baskets at Georgetown, The Gambia

Photo Research International

the peanut (groundnut), a crop still exported downstream on the Gambia River. Georgetown is now a collecting centre for swamp rice and peanuts grown by the local Muslim Malinke (Mandingo), Fulani (Fula), and Wolof peoples. Pop. (1993) 2,800.

**Georgetown**, capital city of Guyana. The nation's chief port, Georgetown lies on the Atlantic Ocean at the mouth of the Demerara River. Although the settlement was founded by the British in 1781 and named after George

III, it had been largely rebuilt by the French by 1784. Known during the Dutch occupation as Stabroek, it was established as the seat of government of the combined colonies of Essequibo and Demerara in 1784. When the British regained control in 1812, the name was changed back to Georgetown.

Many houses and public buildings in the city are constructed of wood, the former generally raised on brick pillars 4–10 feet (1–3 m) from the ground. As a consequence of great fires in 1945 and 1951, however, most buildings in the business sections were reconstructed of reinforced concrete. The public buildings in the centre of the city include the government offices, town hall, and cathedrals. The University of Guyana (1963) is in the suburb of Turkeyen. The city also has an extensive

tol. Georgetown was settled late in the 17th century. It was laid out as a town in 1751, under the name of George. With construction of the Potomac Canal and the town's incorporation as the city of George Town in 1789, it became a bustling trade centre. In 1871 it was merged into the District of Columbia, and in 1878 it was annexed to the city of Washington. Georgetown is largely residential, and its streets are old-fashioned, well-shaded, and narrow. In the "Heights" section are Georgetown University (1789) and many fine homes with beautiful gardens. Legislation was passed by the U.S. Congress in 1950 to preserve the character of the section, to be known as Old Georgetown, which was later designated a national historic district.

**Georgetown**, city, port of entry, seat of Georgetown county, eastern South Carolina, U.S. It lies near the Atlantic coast where the Pee Dee, Waccamaw, Black, and Sampit rivers enter Winyah Bay. An early Spanish settlement there (1526) was abandoned because of fever. The first English settlement was made on the site about 1700, and the community, formally established in 1734, was named for Britain's George II.

As a shipping point for rice, indigo, lumber, and naval supplies, Georgetown influenced the development of coastal South Carolina and has many historic landmarks. The Marquis de Lafayette first landed on American soil (June 13, 1777) at nearby North Island. Occupied by the British during the American Revolution, the town was attacked several times by the American soldier Francis Marion, the "Swamp Fox." Colonial structures include Prince George Winyah Church and the Masonic Lodge. Georgetown's harbour, on the Intracoastal Waterway, has been developed as a deepwater port. Paper is the most important

Prince George Winyah Church, Georgetown, S.C.  
Mill and Joan Mann from CameraMann

manufacture, and tourism (yachting, fishing) is an economic asset. Nearby is Hopsewee Plantation (c. 1740), a restored rice plantation. Also near Georgetown are the Brookgreen Gardens, with more than 400 pieces of sculpture mounted in the gardens of a former rice and indigo plantation that is also a game sanctuary. Horry Georgetown Technical Education Center is in Georgetown. Inc. town, 1805; city, 1892. Pop. (2000) 8,950.

**Georgia**, officially REPUBLIC OF GEORGIA, Georgian *SAKARTVELO*, or *SAKARTVELO RESPUBLIKIS*, a country of Transcaucasia, formerly one of the constituent union republics of the Soviet Union. It lies in the Caucasus Mountains on the southeastern shores of the Black Sea.

Georgia is bounded to the north by Russia and to the south by Turkey, and to the south and southeast by Azerbaijan and Armenia. Within Georgia are the autonomous republics of Abkhazia and Adzharia, inhabited mostly by non-Georgian ethnic groups. The capital of Georgia is Tbilisi. Area 26,900 square miles (69,700 square km). Pop. (2002 est.) 4,961,000.

A brief treatment of Georgia follows. For full treatment, see *MACROPAEDIA: Transcaucasia*.

For current history and for statistics on society and economy, see *BRITANNICA BOOK OF THE YEAR*.

*Physical and human geography.* Most of Georgia is mountainous; many peaks in the Caucasus Mountains are higher than 15,000 feet (4,600 m). It is the Caucasian mountain barrier that protects Georgia against cold air from the north, allowing the Black Sea to warm the region. Western Georgia has a humid, subtropical maritime climate, while in the east climates range from moderately humid to dry subtropical. The fertile Kolkhida lowlands lie near the shores of the Black Sea and are drained by the Rioni and Inguri rivers.

Georgia

It is possible that the Georgians have always lived in this region of the Caucasus; they converted to Christianity in the 4th century. A number of feudal states developed in the region from the 6th century onward, but in the 13th century a population of five million was reduced catastrophically by Mongol and other invasions. Russia annexed Georgia at the beginning of the 19th century. Not until the 20th century did the region's population approach its 13th-century peak. Two-thirds of the people are Georgians, who refer to themselves as *Kartvelebi* (*Kartveli*, or *Kartvelians*). The Georgians speak a language belonging to the Kartvalian (South Caucasian) family. Most Georgians are members of the Georgian Orthodox church. The country's minorities include Armenians (about 8 percent), Russians, and Azerbaijanis.

Georgia has a well-developed industrial base. It stands out as a region of hydroelectric power, mineral extraction, and developing machinery production. Coal, manganese, and nonmetallic minerals are extracted, and steel has been produced since 1956. Georgia's industrial products range from electric railway locomotives, heavy motor vehicles, and earth-moving equipment to lathes and precision instruments. The chemical industry produces mineral fertilizers, synthetic fibres, and pharmaceutical products. Georgia also produces cotton, wool, and silk fabrics and clothing. Agricultural land in Georgia is in short supply and difficult to farm; the production of labour-intensive crops such as tea, citrus fruits, wine grapes, sugar beets, and tobacco is necessary.

City Hall, Georgetown, Guyana

botanical garden, a zoo, a seaside promenade, and many outdoor recreational facilities.

Georgetown is the chief commercial and manufacturing centre of Guyana. It exports sugar, rice, and tropical fruits, as well as timber, balata, bauxite, gold, and diamonds from the Guyanese hinterland. Large sugar refineries are located in the city. Guyana's highway network is poor, although roads do lead along the coast and inland from Georgetown for a short distance. The city is served by various international steamship lines and airlines. Pop. (1999 est.) 275,000.

*A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume*

**Georgetown**, seat (1867) of Clear Creek county, north-central Colorado, U.S. It lies along the South Fork of Clear Creek, in the Front Range of the Rocky Mountains at an elevation of 8,540 feet (2,603 m), 40 miles (64 km) west of Denver. A historic mining town, it originated in 1864 when the Belmont (silver) Lode was discovered nearby, and by the time that the Colorado Central Railroad arrived in 1877, it was producing vast amounts of silver. It was incorporated in 1885 and named for George Griffith, a local official. By the 1890s silver mining had declined and so had the town.

Unlike other Colorado mining towns, Georgetown escaped any major fire, and many original buildings have survived, notably Hamill House (1867) and the Hotel de Paris (1875). The latter was built and operated by an eccentric Frenchman, Louis du Puy, whose outlook and epicurean tastes were extreme; it was during its heyday one of the most elegant hostelrys west of the Mississippi River and is now owned by the Colonial Dames of America. Georgetown remains a tourist base for drives to surrounding ghost towns. The Georgetown Loop Historic Mining and Railroad Park is 2 miles (3 km) west, and the Loveland Basin and Valley Ski areas are nearby. The Eisenhower Memorial (road) Tunnel, penetrating 1.7 miles (2.7 km) through the Continental Divide, is a few miles west. Pop. (2000) 1,088.

**Georgetown**, section of the city of Washington, D.C., U.S., at the confluence of the Potomac River and Rock Creek, about 2.5 miles (4 km) northwest of the national Capi-

There is a well-developed transportation infrastructure.

Relatively free legislative elections were held in Georgia in 1990, being open to various political parties. These elections were won by a coalition of noncommunist parties that declared independence for Georgia in 1991. The government is led by a head of parliament (or president), a prime minister and cabinet, and an elected parliament.

Georgia ranks high in medical services and is famed for its spas. Education is free and compulsory through the secondary level, and attendance is high at every level. Most schools use Georgian as the language of instruction. The Ivan Dzhavakhladze University of Tbilisi was established in 1918.

**History.** The origins of human settlement in Georgia can be traced to early Paleolithic times. There is evidence of tribes engaged in cattle raising and agriculture. The fabled wealth of the region known as Colchis (*q.v.*) was known to the ancient Greeks, and the area was part of the Roman Empire by 65 BC. Georgia embraced Christianity in AD 337, and it was involved in the conflicts between the Byzantine and Persian empires for the next three centuries. After 654 local authority was exercised by Arab caliphs, who established an emirate in the city of Tiflis (Tbilisi). The unification of the lands inhabited by peoples of Georgian and related Caucasian stock was led by the Bagratids, a dynasty prominent in the affairs of Armenia from the end of the 8th century to the beginning of the 12th. King Bagrat III (975–1014) united all the principalities of eastern and western Georgia into one state. The zenith of Georgia's power was reached in the reign (1184–1213) of Queen Tamara; her realm stretched from Azerbaijan on the east to Circassia to the northwest, forming a pan-Caucasian empire.

Invasions of the pan-Caucasian empire by the Mongols from 1220 onward brought Georgia's golden age to an end, and the onslaughts of Timur between 1386 and 1403 dealt blows to Georgia's economic and cultural life from which the kingdom never recovered. The fall of Constantinople (now Istanbul) to the Ottoman Turks in 1453 isolated Georgia from Western Christendom, and the next three centuries saw repeated invasions by the Turks and the Persians. A treaty with Russia was signed in 1783 guaranteeing Georgia's independence in return for Russian suzerainty, but Russia deserted Georgia in the Persian invasion of 1795, and from 1801 to 1864 the Georgian kingdoms were successively annexed by the Russians, who did, however, ensure the survival of Georgia as an entity by successfully repelling attacks from all others.

Owing to World War I and the Russian Revolution, the years 1917–21 saw successively a Transcaucasian state ruled from Petrograd (now St. Petersburg), an independent Transcaucasia, and an independent Georgia. In February 1921 a Soviet regime, the Transcaucasian Soviet Federated Socialist Republic, was installed by the Red Army; it was replaced in 1936 by the Georgian Soviet Socialist Republic as a full member of the Soviet Union. Under Soviet rule Georgia was transformed from an agrarian country to a largely industrial, urban society. In 1990 a noncommunist coalition favouring independence came to power in the first free, multiparty legislative elections ever held in Soviet Georgia. On April 9, 1991, Georgia declared independence.

Georgia's president, Zviad Gamsakhurdia, became increasingly authoritarian and was forcibly deposed in January 1992. His successor from March 1992, Eduard Shevardnadze, was forced to cope with a secessionist rebellion in Abkhazia and other internal threats by cultivating closer ties with Russia. Following a

period of civil unrest, however, Shevardnadze resigned in 2003. Mikhail Saakashvili was elected president in 2004.

**Georgia**, one of the 13 original states of the United States of America, lying in the South Atlantic region, southeastern U.S. It is bounded on the north by Tennessee and North Carolina, on the east by South Carolina and the Atlantic Ocean, on the south by Florida, and on the west by Alabama. The capital is Atlanta.

A brief treatment of Georgia follows. For full treatment, see *MACROPAEDIA: United States of America*.

The Creek and Cherokee Indians were Georgia's original inhabitants. The state was the last of the original 13 American colonies to be settled by European colonists. A charter to settle Georgia was given to James Oglethorpe in 1732 by King George II of Great Britain. Oglethorpe's intention was to set up a colony where convicts, debtors, and other poor people could get a new start. He founded Savannah in 1733, but the colony did not grow immediately. After the American Revolution, white settlement accelerated, especially in a westward direction from Augusta, through the future cotton counties of middle Georgia. This movement forced the removal of the Indians to areas beyond the Mississippi River. The American Civil War (1861–65) was particularly hard on Georgia. General William Tecumseh Sherman's army burned Atlanta and devastated the countryside in the course of his famous March to the Sea. Atlanta recovered, however, to become the premier city of the postwar South.

Northern Georgia is located within the southern end of the Blue Ridge Mountains (part of the Appalachian Mountain system). The state's highest point, Brasstown Bald, is in this range and reaches 4,784 feet (1,458 m) above sea level. South of these mountains is an area known as the Piedmont, a stretch of sandy hills extending from east to west the breadth of the state. South of the Piedmont is the rolling terrain of the coastal plain.

Maritime tropical air masses dominate the climate in summer, but in other seasons continental polar air masses are not uncommon. January temperatures average between 39° and 49° F (4° and 10° C); August, 79° to 82° F (26° to 28° C). In northern Georgia, rain usually averages about 50 inches (1,270 mm) annually. The east-central areas are drier, with about 44 inches (1,100 mm) annually.

In Georgia's earliest days, settlers included the English, blacks, Austrian Salzburger, Scottish Highlanders, New England Congregationalists, and Jews. Except for the increasing number of blacks brought in as slaves (44 percent of the population by 1860), foreign immigration was insignificant after the earliest days. Though the state grew in population during the 20th century, its out-migration exceeded its in-migration until 1960. Black out-migration has been an important factor in the state's demographic makeup, but in the late 20th century blacks nevertheless accounted for almost 27 percent of the total population. As in other southern states, Georgia's population growth rate is well above the national average.

Agriculture in Georgia has followed national trends: farms have become fewer in number but larger in size. Cotton is still a major crop and so are peanuts (groundnuts) and tobacco. Poultry, cattle, and pigs are raised.

Marble and granite are exploited, as is kaolin, a white clay used in ceramic and paper products. Lumber, plywood, and paper are major products, as are naval stores, made from Georgia's extensive pine forests.

Cotton-textile production remains one of Georgia's major industries. Other manufacturing activities include airplane and automobile assembly, mobile homes, chemicals, and food processing. The federal government represents

a significant addition to Georgia's economy through its major military installations.

Navigation of Georgia's inland waterways has been revived, and Savannah and Brunswick are the state's two Atlantic ports. Atlanta has become an important air-travel centre, its airport ranking as one of the country's busiest.

Communications media are highlighted by the *Atlanta Constitution* newspaper and the Cable News Network (CNN), also based in Atlanta. Public institutions of higher learning are headed by the University of Georgia in Athens and by Atlanta's Georgia Institute of Technology and Georgia State University. Area 58,910 square miles (152,576 square km). Pop. (2002 est.) 8,560,310.

**Georgia, Strait of**, narrow passage of the eastern North Pacific between the central east coast of Vancouver Island and the southwest mainland of British Columbia, Canada. It averages 138 miles (222 km) in length and 17 miles (28 km) in width. To the north the strait ends in a jumble of islands separating it from Johnstone and Queen Charlotte straits farther north. The southern end is marked by the San Juan Islands of the U.S. state of Washington. Texada and Lasqueti islands are the largest within the strait, which has a midchannel depth of 900–1,200 feet (275–370 m). The mainland coast is cut by many inlets, one of which is the mouth of the Fraser River and the site of Vancouver. The Fraser's outflow aids a general counterclockwise movement of water in the strait, known locally as the Gulf. The strait forms a link in the scenic and sheltered Inside Passage sea route between Seattle, Wash., and Skagway, Alaska. Its name, honouring George III, was conferred by Captain George Vancouver in 1792.

**Georgia Platform**, statement of qualified support for the U.S. Union among Georgia conservatives following the Compromise of 1850. Drawn up by Charles J. Jenkins and adopted by a state convention on Dec. 10, 1850, at Milledgeville, the Georgia Platform consisted of a set of resolutions accepting the Compromise of 1850. It was not an endorsement of the compromise, but it said that Georgia would abide by the compromise provisions "as a permanent adjustment of the sectional controversy."

The Georgia Platform warned that the state would and should resist any future congressional activity disrupting the interstate slave trade, weakening the fugitive slave laws, or abolishing slavery in the District of Columbia. Such activity could well prompt a dissolution of the Union, according to the platform.

**Georgian Bay**, bay, northeastern arm of Lake Huron, south-central Ontario, Canada. It is sheltered from the lake by Manitoulin Island and the Bruce (or Saugen) Peninsula. The bay is 120 miles (190 km) long and 50 miles (80 km) wide, and the depth (generally 100–300 feet [30–90 m]) reaches a maximum of 540 feet (165 m) near the Main Channel, which leads to Lake Huron.

The principal rivers emptying into Georgian Bay are the French, draining Lake Nipissing; the Muskoka, draining the Muskoka chain of lakes; the Severn, draining Lake Simcoe; the Magnetawan; and the Nottawasaga. The Severn River is part of the Trent Canal, a series of navigable rivers and lakes joined by canals extending southeastward for 240 miles (390 km) to the Bay of Quinte on Lake Ontario. The coast of the bay is indented by Nottawasaga, Matchedash, and Colpoys bays and by Parry and Owen sounds.

The Georgian Bay Islands National Park, established in 1929, comprises some 40 islands in the southeastern and western parts of the bay. The largest is Beausoleil Island (4 square miles [10 square km]), once the home of Ojibwa (Chippewa) Indians. Another, Flowerpot Island, is named for two giant flowerpot-shaped

pillars that were sculptured from limestone cliffs by the waves. The park's landscape is varied and includes glacier-scraped rocks and some dense forests. The Thirty Thousand Islands that lie along the bay's eastern shore constitute another popular summer resort area.

The surrounding region is well forested except for an apple-growing area along the southern shore. The bay's important commercial shipping focusses on the ports of Parry Sound, Port McNicoll, Collingwood, Midland, and Owen Sound.

The French explorer Samuel de Champlain was the first European to record seeing part of the Great Lakes when he reached Georgian Bay from the north in 1615. The bay was named for Britain's George IV by Captain Henry Bayfield of the Royal Navy.

**Georgian language,** Georgian KARTULI ENA, official language of the Republic of Georgia, whose spoken form has many dialects, usually divided into East Georgian and West Georgian groups. These, together with the related Mingrelian (Megrelian), Laz (Chan), and Svan languages, make up the Kartvelian, or South Caucasian, language family. Georgian is also spoken in parts of Azerbaijan and northeastern Turkey and in many villages in the region of Eşfahān in Iran.

The Georgian literary tradition, in the form of inscriptions, dates back to the 5th century. Many literary monuments remain from the Old Georgian period (5th–11th century), among them a translation of the Bible. The New Georgian literary language is based on an East Georgian dialect and originated in the secular literature of the 12th century; it became fully established in the middle of the 19th century. Old Georgian was used for religious purposes until the beginning of the 19th century.

New Georgian has five vowels and 28 consonants; Old Georgian had five vowels but 30 consonants. Georgian has roughly the same parts of speech as do the Indo-European languages. The noun has seven cases, and the adjective, usually preceding the noun it modifies, agrees with the noun in case but not in number.

Historically, the Georgian language was written in two scripts: Khutsuri, an ecclesiastical script of 38 letters, including 6 vowels, is no longer in use; Mkhedruli, a lay alphabet originally of 40 letters (7 are now obsolete), 6 of them vowels, is the script commonly used at present in printing and handwriting. Both scripts are written from left to right.

The Old Georgian script must have been derived from the Greek alphabet. This is suggested by the order of the alphabet (which reflects the Greek sequence) and the shape of some of the characters, although the angular shape of the majority of signs of the Old Georgian script appears to be a result of a free creation of its inventor.

The modern Georgian script is based on the round-form cursive, which was developed from the angular book script of the 9th century; the latter was a direct descendant of the Old Georgian system.

**Georgian literature,** body of writings in the Georgian language.

Georgian literary history began with the area's conversion to Christianity in the 4th century and a need to invent an alphabet for the propagation of the Scriptures in the vernacular. The Gospels were translated in the 5th century into Georgian, and the Acts of the Apostles and Psalms were translated soon afterward, as were works of early Greek Fathers.

Original Georgian literature began with biographies of saints, the first one being that of St. Shushanik (c. 480), and other early works include an account of the conversion of Georgia by the holy woman known as St. Nino in addition to stories about King Vakhtang I

Gorgasal, a 5th-century hero. Georgian ecclesiastical literature was rooted in Byzantine Greek culture, and Georgian romances and epics blended the civilization of Persia with original elements of Caucasian folklore. Important prose romances were the *Visramiani* ("Visramiani: The Story of the Loves of Vis and Ramin"), adapted from an Iranian romance dating to Parthian times, and *Aniran-Darejaniani*, a cycle of fantastic tales. Secular poetry started with Ioann Shavteli and Chakhrukhadze, who wrote odes in honour of King David II (d. 1125) and Queen Tamara (d. 1213). The supreme achievement of Georgia's golden age was Shota Rustaveli's epic *Vepkhis-tqaosani* (*The Knight in the Panther's Skin*) on the themes of ideal comradeship, courtly love, and heroic endeavour. His poetic tradition, broken by Mongol invasions, was renewed in the 17th century by the Georgian royal poets Teimuraz I and Arehil II.

Belles lettres revived in Georgia during the 18th century with the lexicographer Sulkhana-Saba Orbeliani, who wrote a book of fables, *The Book of Wisdom and Lies*. The main poets of the period were David Guramishvili and Bissarion Gabashvili.

The Russian occupation of 1801 brought Georgia into the orbit of European intellectual life. Romantic poetry flourished with the work of Alexander Tchavtchavadze and the Byronic lyrics of the youthful bard Nicholas Baratashvili. Satirical comedy developed under the lead of Giorgi Eristavi, founder of the modern Georgian theatre. Exponents of the realistic novel were Lavrenti Ardaziani and Iliia Tchavtchavadze, the latter being Georgia's most distinguished man of letters of modern times, renowned as an essayist, publicist, and poet. The life of the Georgian mountaineers is brilliantly portrayed in the stories of Alexander Qazbegi and the ballads of Vazha Pshavla. Even more famous was the patriotic poet and man of letters Akaki Dsereteli (Tsereteli).

Under the tsarist regime Georgian literature often assumed a propagandistic, moralistic tone. A number of leading writers, including the novelist Mikheil Javakishvili and the poets Paolo Iashvili and Titsian Tabidze, perished in the Stalinist purge of 1937. However, poets of the stature of Ioseb Grishashvili and Ana Kalandadze, dramatists such as Shalva Dadiani, and novelists such as Konstantine Gamsakhurdia succeeded in maintaining a high standard of creative originality during the Soviet era.

**Georgian Orthodox church,** autocephalous (independent) church of the Orthodox communion in Georgia. The church is one of the most ancient Christian communities in the world. The Georgians adopted Christianity through the ministry of a woman, St. Nino, early in the 4th century. Thereafter, Georgia remained in the ecclesiastical sphere

of Antioch and also under the influence of neighbouring Armenia. Its autocephaly was probably granted by the Eastern Roman emperor Zeno (474–491) with the consent of the patriarch of Antioch, Peter the Fuller. The heads of the Georgian church have since that time borne the title of catholicos.

In the Middle Ages, Georgia experienced several periods of political expansion, during which the church developed remarkably rich traditions of art, architecture, and literature.

In 1801, having been annexed by Russia, the country lost its political and ecclesiastical independence, and after 1817 the Georgian church was governed by Russian exarchs. During the Russian Revolution of 1917, the church reestablished its autocephalous catholicate. It was severely persecuted during the 1920s by the Soviet government, but under the Soviet leader Joseph Stalin, a former Georgian seminarian, it seems to have enjoyed favourable treatment. In 1977, after the election of Catholicos Elias II, several vacant dioceses received new bishops, and a seminary, located in the historical seat of the catholicos in Mtskheta, was reorganized.

**Georgian poetry,** a variety of lyrical poetry produced in the early 20th century by an assortment of British poets, including Lascelles Abercrombie, Hilaire Belloc, Edmund Charles Blunden, Rupert Brooke, William Henry Davies, Ralph Hodgson, John Drinkwater, James Elroy Flecker, Wilfred Wilson Gibson, Robert Graves, Walter de la Marc, Harold Monro (editor of *The Poetry Review*), Siegfried Sassoon, Sir J.C. Squire, and Edward Thomas.

Brooke and Sir Edward Marsh, wishing to make new poetry accessible to a wider public, with Monro, Drinkwater, and Gibson, planned a series of anthologies. To this series they applied the name "Georgian" to suggest the opening of a new poetic age with the accession in 1910 of George V. Five volumes of *Georgian Poetry*, edited by Marsh, were published between 1912 and 1922.

The real gifts of Brooke, Davies, de la Marc, Blunden, and Hodgson should not be overlooked, but, taken as a whole, much of the Georgians' work was lifeless. It took inspiration from the countryside and nature, and in the hands of less gifted poets, the resulting poetry was diluted and middlebrow conventional verse of late Romantic character.

**Georgian style,** the various styles in the architecture, interior design, and decorative arts of Britain during the reigns of the first four members of the house of Hanover, between the accession of George I in 1714 and the death of George IV in 1830. There was such diversification and oscillation in artistic style

Entrance hall of Syon House (1762–69), in the London borough of Hounslow, designed by Robert Adam in the Neoclassical Georgian style

A.F. Kerling

during this period that it is perhaps more accurate to speak of "Georgian styles."

For the first 50 years of the Hanoverian dynasty the same Whig aristocracy that controlled the government also dictated artistic thought. The splendid architectural achievements of Sir Christopher Wren and his followers during the reigns of the three preceding Stuart monarchs were in the extravagant and monumental Baroque style of continental Europe, which the Whig aristocrats eventually judged to be of questionable taste. Thus, the new generation of architects, theorists, and wealthy amateurs set out to reform architecture in accordance with the classical tenets of the Italian architect Andrea Palladio (see Palladianism). The second important Georgian architectural style, Neoclassicism, came into fashion about the mid-18th century. The models for the architecture of this period were no longer the buildings of the Italian Renaissance but those of Classical Greece and Rome. Neoclassicism's austere use of Doric and Ionic architectural elements increasingly dominated English architecture in the late 18th century. Toward the end of the century and during the reign of George IV, a number of other styles of building and interior decoration became popular, chief among them Gothic Revival and the Regency style (*q.v.*).

In addition to architecture and interior design, the Georgian era saw great achievements in the decorative arts. Technical as well as aesthetic advances were made in pottery by Josiah Wedgwood and Josiah Spode. Paul de Lamerie, working primarily in the Rococo style, was preeminent among English silversmiths of the early to mid-18th century, after which the Neoclassical designs of the Adam family dominated this craft. Furniture design encompassed a variety of distinct and memorable styles, ranging from the complicated curves of pieces by Thomas Chippendale (mid-18th century), to the classical influence of the Adams, to the straight, simple lines of the works of George Hepplewhite and Thomas Sheraton. It was also during the Georgian era that wallpaper came to supplant wood paneling as the preferred method of covering interior walls.

The Georgian era is notably remembered as marking the summit of house design in Britain. Its legacy can be seen in the entire city squares of uniform, symmetrical townhouses in London, their facades employing classical pilasters, pedimented doors and windows, and graceful moldings. These houses' interiors—with harmonious proportions, quiet colours, Roman-derived stucco ornamentation, and Chippendale and Sheraton furniture—once made elegant settings for the paintings of Reynolds and Gainsborough that adorned the walls.

*A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume*

**Georgievsk, Treaty of** (July 24, 1783), agreement concluded by Catherine II the Great of Russia and Erekle II of Kartalinia-Kakhetia (eastern Georgia) by which Russia guaranteed Georgia's territorial integrity and the continuation of its reigning Bagratid dynasty in return for prerogatives in the conduct of Georgian foreign affairs.

Under the terms of the treaty, Catherine and her heirs were to defend Georgia against enemies, and Erekle renounced dependence upon Iran or any other power. Though the treaty was to have permanent validity, Emperor Paul I's manifesto of Dec. 18, 1800, unilaterally declared the annexation of Kartalinia-Kakhetia to Russia, and on Sept. 12, 1801, his suc-

cessor, Alexander I, formally reaffirmed this determination.

**Geórgios** (Greek personal name): *see under* George.

**geórgoi** (ancient Greek social class): *see* geómoroi.

**geostrophic motion**, fluid flow in a direction parallel, rather than perpendicular, to lines of equal pressure (isobars) in a rotating system, such as the Earth. Such flow is produced by interaction of the Coriolis force (*q.v.*; caused by the Earth's rotation) and the pressure-gradient force. The velocity of the flow is proportional to the gradient of the pressure. Although observed fluid motions are not strictly geostrophic, large-scale oceanic and atmospheric movements approach the ideal; that is, the geostrophic current usually represents the actual current within about 10 percent, provided the comparison is made over large areas.

On a nonrotating Earth, the pressure-gradient force would cause the wind to blow directly from a region of high to one of low pressure, across isobars. Because the Earth does rotate, however, the Coriolis force deflects the wind into parallelism with the isobars. The Coriolis force deflects the wind to the right in the Northern Hemisphere and to the left in the Southern Hemisphere.

Near the surface, friction between the air and the surface causes the wind to blow at less than a right angle to the pressure gradient. Near the Equator, where the Coriolis force is weak (because it is a function of latitude), the wind generally blows toward low pressure. The geostrophic-wind concept is useful in weather forecasting because it facilitates the mapping of wind streamlines in regions where wind observations are sparse, and of isobars where pressure data are scanty. *See also* gradient wind.

**geosyncline**, linear trough of subsidence of the Earth's crust within which vast amounts of sediment accumulate. The filling of a geosyncline with thousands or tens of thousands of feet of sediment is accompanied in the late stages of deposition by folding, crumpling, and faulting of the deposits. Intrusion of crystalline igneous rock and regional uplift along the axis of the trough generally complete the history of a particular geosyncline, which is thus transformed to a belt of folded mountains. The concept of the geosyncline was introduced by the American geologist James Hall in 1859 and is basic to the concept of mountain building.

Two segments of a geosyncline are recognizable in the rock strata of many of the world's mountain systems today. Thick volcanic sequences, together with graywackes (sandstones rich in rock fragments with a muddy matrix), cherts, and various sediments reflecting deep-water deposition or processes, were deposited in eugeosynclines, the outer, deepwater segment of geosynclines. The occurrence of limestones and well-sorted quartzose sandstones, on the other hand, is considered to be evidence of shallow-water formation, and such rocks form in the inner segment of a geosyncline, termed a miogeosyncline.

Aside from the parts or segments of a geosyncline, several types of mobile zones have been recognized and named. Among the more common of these are the taphrogeosyncline, a depressed block of the Earth's crust that is bounded by one or more high-angle faults and that serves as a site of sediment accumulation, and the paraliageosyncline, a deep geosyncline that passes into coastal plains along continental margins.

**geothermal energy**, power obtained by using heat from the Earth's interior. Most geothermal resources are in regions of active volcanism. Hot springs, geysers, pools of boiling

mud, and fumaroles (vents of volcanic gases and heated groundwater) are the most easily exploited sources of such energy. The ancient Romans used hot springs to heat baths and homes, and similar uses are still found in some geothermal regions of the world, such as Iceland, Turkey, and Japan. The greatest potential for geothermal energy, however, lies in the generation of electricity. Geothermal energy was first used to produce electric power at Larderello, Italy, in 1904. By the late 20th century, geothermal power plants were in operation in Italy, New Zealand, Japan, Iceland, Mexico, the United States, and elsewhere, and many others were under construction in other countries.

The most useful geothermal resources are hot water and steam trapped in subsurface formations or reservoirs and having temperatures ranging from 176° to 662° F (80° to 350° C). Water and steam hotter than 356° F (180° C) are the most easily exploited for electric-power generation and are utilized by most existing geothermal power plants. In these plants the hot water is flashed to steam, which is then used to drive a turbine whose mechanical energy is then converted to electricity by a generator. Hot, dry subsurface rocks may also become more widely used as a source of geothermal energy once the technical problems of circulating water through them for heating and conversion to steam are completely resolved. The development of geothermal resources has become increasingly attractive owing to the rising cost of petroleum and the nonpolluting character of geothermal energy production.

**Geougen** (Central Asian people): *see* Juanjuan.

**Gepidae**, a Germanic tribe that lived on the southern Baltic coast in the 1st century AD, having migrated there from southern Sweden some years earlier. The Gepidae again migrated during the 2nd century and were reported in the mountains north of Transylvania by the end of the 3rd century. They united with other tribes in an assault on the Roman Empire but were crushed in 269 in a battle near Naissus (Niš). In 454 they and other Germanic tribes decisively defeated the Huns on the unlocated Nedao (Nedad) River in Pannonia, a province south and west of the Danube.

Intermittent wars occurred between the Gepidae and the Lombards from 536 to about 567, when the Gepidae were finally crushed by a coalition of Lombards and Avars. Thereafter, the Gepidae became submerged in Avar domains.

**ger** (tentlike dwelling): *see* yurt.

**Gera**, city, Thuringia *Land* (state), east-central Germany. It lies along the Weisse Elster River, southwest of Leipzig. First mentioned in 995 and by 1237 referred to as a town, it became part of the principality of Meissen in 1547. Passing to the Reuss family in 1562, it became their residence and capital from 1564 to 1918. Although largely destroyed by fire in 1639, 1686, and 1780, the city was always rebuilt. It suffered heavy damage in World War II, after which a new city centre was built. The Osterstein Palace (1686–1735) was the seat of the Reuss princes. There are Baroque and Renaissance buildings around the market square. A rail junction, Gera manufactures textiles, metal products, machinery, fats, oils, and furniture. Nearby are mines producing uranium ore. Pop. (1990 est.) 132,257.

**Gerald of Wales**, also called **GERALD DE BARRI**: *see* Giraldus Cambrensis.

**Geraldton**, town and Indian Ocean port, southwestern Western Australia. It lies along Champion Bay, across Geelvinck Channel from the Houtman Abrolhos (islands). Surveyed in 1850, Geraldton originated as a mili-

tary post for the nearby Murchinson goldfield and was declared a town in 1871. During World War II it was used as a U.S. amphibious air base. Geraldton is linked to Perth (230 miles [370 km] southeast) by rail, air, and the Brand Highway and Midlands Road. It is now the state's second largest port, serving as the outlet for the northern Wheat Belt and a hinterland producing barley, oats, lupines, fruits, and tomatoes. Live sheep, mineral sands, gold, iron ore, and talc are also shipped, and natural gas is tapped. Geraldton has superphosphate plants, and crayfish are caught and exported. The town, which has Roman Catholic and Anglican cathedrals, is a winter resort. Pop. (1991 prelim.) 20,590.

**Geraniales**, the diverse geranium order of flowering plants, belonging to the class Magnoliopsida (dicotyledons; characterized by two seed leaves). It consists of 5 families and some 3,600 species. Most members of the order are herbaceous, with a superior compound ovary and one to two ovules per locule. Many of the economically important families of Geraniales require rich, moist soil.

The wood-sorrel family (Oxalidaceae) is composed of some 900 species readily recognized by their three cloverleaf-like leaflets. Most of the Oxalidaceae are herbs found in tropical

*Impatiens walleriana*  
Barry L. Runk from Grant Heilman Photography

regions; some are weeds in temperate regions, and still others are grown as ornamentals.

The geranium family (Geraniaceae), consisting of 14 genera and some 700 species, is worldwide in distribution and generally grows in temperate or subtropical regions. The florist's geranium (*Pelargonium* × *domesticum*) is a favourite house plant and is available in many varieties. These cultivars (horticultural varieties) have originated from plants native to South Africa. Herb Robert (*Geranium robertianum*) is a well-known garden plant, as are some species of *Erodium*. The pin-clover (*E. cicutarium*), a Mediterranean species now naturalized in the United States, is a weed, but in California it is grown as a forage crop. Geranium oil, used in perfumes, is produced by *Pelargonium odoratissimum* and related species.

The remaining families of the Geraniales order are of lesser economic importance; some are, however, important locally for food and ornamental plantings, and many are of scientific interest. The family Balsaminaceae has 2 genera and some 900 species of subsucculent annual or perennial plants. Some species of *Impatiens* are cultivated. Nasturtiums of the Tropaeolaceae, which are garden plants suited to moist habitats, yield spicy buds containing mustard oil for seasoning. Of the nearly 100 species in this genus, *Tropaeolum tuberosum* of the high Andes is an important vegetable-tuber crop. Limnanthaceae has 2 genera and 8 species of small, subsucculent annual plants, found in temperate parts of North America. Some species of *Limnanthes* are used as ornamentals, and they have attracted interest as a source of oilseeds.

Many members of the *Oxalis* genus prop-

agate vegetatively. Reproduction by seeds is, however, the universal method of perpetuating the species of this order. Inflorescences of the Geraniales range from those set closely on an elongated flowering stalk (spike) to branched clusters (panicles). A few flat-topped flower clusters (umbels) are produced in the wood-sorrel and balsam families. A representative flower of the Geraniales possesses five sepals and an equal number of petals of similar size and shape, 10 stamens in two whorls, and a pistil composed of five carpels. Sepals are joined basally to form a short funnel; petals are separate, and stamens are joined at their base. The ovary portion of the pistil consists of five chambers, each containing one ovule. Five separate styles end in pollen-receptive stigmas.

Insects are the almost universal agents of Geraniales pollination. The fragrant flowers of the garden geranium are visited by nocturnal insects. Some North American species of *Impatiens* are pollinated by hummingbirds. After pollination and fertilization, the ovule becomes the seed and the ovary the fruit. In some families, the fruit ripens dry and splits at maturity into segments (mericarps), or, in other species, the fruits open completely (capsule).

**geranium**, also called CRANESBILL (genus *Geranium*), any of a group of about 300 species of perennial herbs or shrubs in the family Geraniaceae, native mostly to subtropical southern Africa. Geraniums are among the most popular of bedding and greenhouse plants. The closely related genus *Pelargonium* contains some 280 species of annual, biennial, and perennial herbaceous plants that are commonly called geraniums.

The cultivated geraniums of the genus *Pelargonium* are herbaceous to woody, with thick fleshy leaves varying in shape from round to lobed to deeply cut; the flowers, borne in terminal clusters, vary in colour from white through shades of pink to deep red and violet. Most of the cultivated species are hybrids. Double flowers and mixed colours as well as ragged or frilled petals are available. While mostly propagated by stem cuttings, from which flowering plants can be produced in four or five months, geraniums are also grown from seed. Breeding and selection has resulted in a line of seed geraniums useful in

Hybrid geranium (*Pelargonium* × *hortorum*)  
John H. Gerard

bedding for their regular symmetry, elongated flower stalks, and habit of rapid and clean dropping of flower petals.

The show, or Martha Washington, geraniums (*P.* × *domesticum*, largely derived from *P. cucullatum*, *P. angulosum*, and *P. grandiflorum*) have large pansylike flowers, few to the cluster.
